Dr. LEONARD GUTHRIE believed that there are well authenticated instances of the spontaneous disappearance of tumours, both malignant and benign. He suggested that the phenomenon might be due to interference with the blood supply of the tumours. This explanation might be opposed to the effects of phrynin and various drugs vaunted as cures for cancer. For instance, carbonate of lime, chian turpentine and cinnamon, which latter contained tannic acid. Finally, the success which sometimes followed opphorectomy for inoperable cancer of the breast was possibly due to the profound effect produced by that operation on the work

of the sympathetic system.

Dr. WASHBOURN mentioned some observations which had been made by Mr. Bellingham Smith and himself upon infective sarcomata occurring in dogs, and which they had published in the Pathological Society's Transactions, and in the British Medical Journal. The sarcomata were originally situated in the mucous membrane of the vagina and penis, and were transmitted from animal to animal during the act of cortus. They consisted of round cells with an alveolated arrangement, and were similar in structure to the round-celled alveolar sarcomata met with in the human subject. By inoculation they would be transmitted to the subcutaneous tissue of dogs. At the end of two or three months the resulting tumours reached their maximum development, forming lobulated masses about two inches in diameter. They then took one of two courses. Either they became disseminated, secondary nodules appearing in the internal organs causing the death of the animal; or they disappeared. In the latter case they either slowly dwindled away, being replaced by fibrous tissue, or they disappeared by a process of ulceration. A most interesting point was the fact that after the tumour had disappeared, the animals were absolutely immune to subsequent inoculation. Up to the present time no micro-organisms bearing a causal relationship to the tumour had been discovered.

Mr. D'ARCY POWER replied.

A NEW FORM OF ETHER INHALER.

Mr. Bellamy Gardner showed an improved ether inhaler which he had devised. Its advantages were:

being emitted upon a sponge by simply turning a tap; (3) compactness and portability in the filled condition. He had used it in over 700 cases during the past two and a-half years, and recommended it as combining the advantages of Clover's and Ormsby's inhalers.

In answer to questions by Dr. Cock and Mr. Eastes, Mr. Gardner stated that the supply of ether could be accurately regulated, and that with ordinary care there was no fear of any fluid ether entering the face-piece.

> LIVERPOOL MEDICAL SOCIETY. MEETING HELD FEBRUARY 23RD, 1899.

The President, Dr. MACFIE CAMPBELL, in the Chair.

MR. HUGH E. JONES exhibited patients on whom the operation of discission of the crystalline lens had been

performed for high myopia.

Mr. F. T. PAUL submitted a case of cholecystectomy for gall-stones and cancer. The tumour was a small villous carcinoma of the fundus of the gall-bladder, which was removed, together with the upper half of the organ and thirteen gall-stones. The patient recovered from the operation in a few weeks, but two-and-a-half months subsequently died from enlargement of the liver, which was apparently not due to recurrent cancer, but to some inflammatory condition, probably set up by stones in the hepatic ducts.

Mr. RUSHTON PARKER remarked that few operations were more gratifying to the surgeon and patient than the removal of gall-stones. He took it that Mr. Paul in this case excised the gall-bladder, because being discovered in the search for gall-stones to be cancerous it appeared removable, and was not thereby advocating the general removal of similarly affected gall-bladders as

ninted at by one speaker.

Mr. ROBERT JONES related the case of a youth of 16 who came to him because of difficulty in flexing his knee, caused by a hard mass apparently attached to the upper two-thirds of thigh, which interfered with muscular action. Further growths were found on the inner aspect of right jaw below ramus a small lump below right olecranon; thickenings at insertion of right patella, and at each first tarso-metatarsal joint. His back presented an extraordinary spectacle. Over the spinous processes a continuous line of hard material, cartilaginous or bony, extended from the level of the fifth dorsal to the fourth lumbar spine. This central ridge bifurcated at the lower end, the extremities of the bifurcated portions almost reaching to the iliac crests. From the central tissue two transverse strips projected at the upper end, and two at the lower, almost symmetrical in appearance. The upper ones arose about the level of the seventh dorsal and were about two inches in length: the lower ones at the level of the second lumbar, the right being about three inches long, and the left two inches. These prolongations were movable, and the fingers could be placed under their tips. The boy was unable to stand absolutely erect from the fact that extension of the spine resulted in the jamming of structures in contact with the lower end of the prominence. Four years ago the patient fell on a door-step and hurt his back; a year later the growth started in the centre of the spine. The origin of the tumour of the jaw cannot be fixed. The thickening at the elbow started after a blow, and the tumour of the thigh has lasted four months. Mr. Jones purposes removing the growth on the back, and any other deposits which may interfere with breathing.

Dr. ALEXANDER read notes of a case of "Pylorectomy" for Stenosis of the Pylorus, Murphy's button was employed, and the patient quickly recovered.

Dr. Briggs read a paper on

VAGINAL SECTION.

The paper was mainly based on sixteen operations in the author's practice. In thirteen posterior vaginal section, and in three anterior vaginal section was the (1) a breathing channel two inches in diameter; (2) a operation performed. The cases treated by posterior reservoir for six ounces of ether, the quantity required vaginal section included five of hæmatocele due to

ectopic pregnancy, three of tubo-ovarian cyst (ovarian hydrocele), one of simple papilloma of both ovaries, one of hydro-salpinx, one of chronic infective salpingo-cophoritis, two of chronic infective metro-salpingo-oöphoritis (with hysterectomy)—thirteen in all. The cases treated by anterior vaginal section included three of chronic salpingo-cophoritis with retroversion, for each of which, after the removal of the ovary and tube, the uterus was steadied forwards by vaginal fixation. In hæmatoceles, the vaginal drain was employed in chronic cases, and the important question seemed to be: Was it necessary to empty or remove the Fallopian tube, in cases of incom-plete tubal abortion or tubal mole? The uncertainty of being able to recognise the tubal condition ought not to be disregarded until it had been shown that drainage alone was sufficient. Dr. Briggs explained that in three of his cases a portion of the outer end of the tube was removed, and in two cases the tube was neither felt nor seen. All the cases recovered equally well, with the exception of one where the patient was lost sight of and the unhealed sinus suppurated. Operators seemed to agree that the tubes and ovaries might be left behind. In the one case where suppuration occurred the tubes were excised by another operator and found empty, four months afterwards available evidence pointed towards posterior vaginal section as the operative treatment of chronic hæmatocele distending the pouch of Douglas. Similarly tubo-ovarian cysts (ovarian hydroceles), simple papilloma-growths, and salpingo-oophoritic lesions, if accessible from below, could be removed from the pouch of Douglas by posterior vaginal section. It is evident that where there is matting, thickening and firm fixation, especially towards the lateral walls of the pelvis, there is difficulty in securing the pedicle. More room is obtained by removing the uterus, which in infective inflammation is often, as Landau has urged, in an incurable state. Dr. Briggs removed the uterus in two of the cases quoted because of the conditions alluded to. One patient lost her life from hæmorrhage thirty hours after operation, the hæmorrhage had been concealed behind the cyanide-gauze pack, and escaped the notice of the attendants in charge of her. This case was a posterior vaginal section for adherent hydrosalpinz, with thickened broad ligaments and enlarged stiffened uterus. The specimen (pelvic organs) post-mortem was carefully examined, the stump was apparently securely held by the silk ligatures, still in situ, the end of the stump swollen and its margins recurved; the uterine artery was tested by injection, water oozed through the vessels of the stump, but a thicker pigmented starchy solution would barely pass. Shrinkage of the stump and probably difficulty in securing the proper constriction of thick rigid tissues, rendered tense by forcible traction during operation, explained the incomplete hæmostasis. The results in the cases of removal of the appendages with vaginal fixation for retroversion affected by anterior vaginal section, were too recent to report upon. In sixteen cases there had been one death from hæmorrhage. A summary of the difficulties and dangers would lead one to advocate the exclusion of densely matted and thickened appendages.

Dr. Burton congratulated Dr. Briggs on the way in Dr. Burton congratulated Dr. Briggs on the way in which he had brought forward his paper. He had not himself opened Douglas's pouch for hæmatoceles, as all his cases during the year had got better without, and he agreed with the reader of the paper that they generally did if left alone. At the same time he was of opinion that by operation the patient's stay in hospital would often be shortened. He had opened the peritoneum per vaccinum himself six times during the year for inflammavaginum himself six times during the year, for inflamma-tory tubal affection, removal of enlarged ovaries, and once for removal of a dermoid containing about 12 ozs, of fat, there was less shock than by the abdominal route. He was rather enamoured of the operation, as by it a scar was avoided, as was also danger of ventral hernia in

cicatrix.

Dr. GRIMSDALE said that he considered that owing to the want of accurate diagnosis in pelvic disease the vaginal operation should be limited to the most simple cases. Slight errors in accurate diagnosis were more likely to assume graver proportions during vaginal operations than during abdominal operations. He did not

suppose that anyone would contend that the actual opening of the peritoneum was safer in one spot than in the other. The ease of the operation would, therefore, be in the long run, the measure of the safety of any particular method of attack.

Drs. E. T. Davies and Gemmell also made remarks, and Dr. Briggs, in reply, stated that the advantages of the vaginal route were indisputable in suitable cases.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A Clinical Meeting was held in the Society's Rooms at the West London Hospital, Friday, March 3rd, 1899.

Dr. S. D. CLIPPINGDALE, President, in the Chair.

Dr. Andrew Elliot showed a case of well marked locomotor ataxy in a women. Mr. William John asked

Mr. McAdam Eccles showed for Dr. G. P. Shuter a woman who was a survivor of the Faversham detonator explosion She had lost her sight, and suffered amputation of the left forearm.

The President showed a young woman who exhibited a want of development of the forearm and hand.

Mr. HOWLAND POLLOCK showed two brothers with multiple want of development of hands and feet

Mr. McAdam Eccles showed a man with marked arrest

of growth of the right upper limb

These cases of deformity were admirably demonstrated

on the fluorescent screen by Dr. F. H. Low. Remarks were made by Messrs. H. P. Potter, E. P. Paton, P. Abraham, F. Savory, W. C. Musson, and Vaughan Pendred

Mr. Brindley James showed a young man with a deep sulcus above and behind the upper part of the manubrium sterni. Messrs. McAdam Eccles, and E. P. Pator made remarks.

Dr. Andrew Elliot for Dr. Seymour Taylor showed a man who presented many of the symptoms of myxce-

Mr. McAdam Eccles showed a man with a marked nævoid condition of the penis and scrotum.

Mr. VAUGHAN PENDRED exhibited (1) a girl, æt. 19, who had marked symptoms of what appeared to be pseudo-hypertrophic paralysis; (2) a case of possibly early acromegal

Dr. ARTHUR HAYDON discussed the cases.

Lunacy Department.

ROYAL EDINBURGH LUNATIC ASYLUM.

THE Annual Report of the Edinburgh Royal Asylum for the Insane has always been looked forward to of late years with interest by all interested in the management of asylums and the treatment of the insane, for especially in Scotland is Morningside looked to as a place of light and leading, and Dr. Clouston as an advanced and original thinker and observer. The prosperity of Morningside everyone hopes for, for many excellent advances have been made in the last twenty five years—the period of Dr. Clouston's regime—in the direction of more liberal treatment of the insane and more skilled methods of treatment, so that the present advanced methods which distinguish many asylums are largely due to the promulgation of Dr. Coulston's ideas of the hospital, as distinct from the old asylum, as the proper conception of the treatment of insanity. One therefore looks with interest for the annual report of Dr. Clouston to learn what he may have to say. It is not so much that he often appears to be original in his views, for it may truly be aid of many that here there is really nothing new under the sun, but that he dresses them up in such an attractive garb so as to give the freshness of a new dressing or new fashion to the idea. For example, he repeats the statement that cases are now sent more readily to asylums, and it has been stated time and again by others in their annual reports, vis., that the number of

Digitized by Google

admissions to asylums increases, not much from increase of insanity, but from a more favourable conception in the public mind of the resources and conditions of asylums. The generally accepted fact that there are many degrees of insanity, and there are as well many degrees of sanity, Dr. Clouston expresses in this way —"It is getting better understood that many forms of mental disease are just morbid accentuations of natural disposition—in one case, temper shading off into mania; in another, keen sensitiveness of feeling passing into melancholia; and in a third, suspiciousness verging into insane delusions so that the subjects of such changes become unfit for family or social life. The world is getting too for family or social life. The world is getting too busy to be able to attend to its mental breakdowns at home, and it is getting more intolerant of very marked divergencies from social order and even of the neglect of the conventionalities of life. The man with typhoid fever is now more frequently sent than he was formerly to an infectious hospital on account of the risk to others. For somewhat the same reason a patient who from morbid peculiarities is causing a mental strain and risk of breakdown in other members of his family is sent to a mental hospital." The outcome of this seems to be, and it is one real explanation of much of the so-called increase of insanity, that human nature has become more selfish. Men and women are not willing to deny themselves their comforts, luxuries, and ease and their social enjoyments for the sake of their less fortunate brothers and sisters. If this is true it is as well to face the matter honestly, and, instead of continually trying to throw the blame on other and wrong causes, to acknowledge the fact and, therefore, to admit that we must pay for our selfishness.

France.

SURGICAL ANÆSTHESIA IN URINARY AFFECTIONS.

M. Bazy drew attention to the modes of anæsthesia in the surgical treatment of the urinary tract, these being local, general, and mixed. Local anæsthesia rendered incontestable services, but he was of the opinion that the employment of cocaine was not unattended with danger, as he had heard of cases in which the injection of a solution of cocaine into a healthy bladder was followed by a fatal result. However, he himself had introduced very large doses of cocaine into diseased bladder for a considerable time, and without any inconvenience to the patient, yet he did not feel warranted in disregarding the accidents experienced by others, and at the present time in the very rare cases in which he used cocaine in exploring the bladder he did not inject more than two grains. On the other hand, he used freely cocaine in affections of the urethra at a dose of 1-100.

In very nervous persons he had recourse to the mixed form of anæthesia; concurrently with the local application of cocain, he gave a few drops of chloroform in inhalation, just enough to allay the fears of the patient.

For general anæsthesia he employed chloroform, ether, or bromide of ethyl. Although he preferred the chloroform, he used ether in young persons of weakened constitution and chloroform in elderly patients, and who in general supported ether badly. As to bromide of ether, he reserved it for operations that took but a short time to execute, such as internal urethrotomy, phymosis and some cases of lithotrity.

The effect exerted by chloroform on a healthy bladder was rapid and continued, even in small doses. The organ was patient and tolerant, and did not present those irregular contractions which hindered so much the

surgeon and obliged him to suspend the operation until the muscular walls had become flaccid. The influence of the anæsthetic on the urethra in its three divisions is well marked, allowing catheters of considerable dimensions to pass through a canal rendered rigid and tortuous by a diseased or enlarged prostate.

THE TREATMENT OF APPENDICITIS.

M. Tillaux in referring to this constantly recurring subject at the Academy of Medicine, said that he protested against the declaration of his colleague, M. Dieulafoy, that no one should ever die from appendicitis, for it was in contradiction with facts observed by him and many others of his colleagues almost daily. He similarly protested against the aphorism that there was no medical treatment of that affection. On the contrary they all knew that the greater number of appendicitis terminated in resolution. The medical treatment was not therefore a chimera, for it was frequently successful. An operation should only be performed where the formation of an abscess was suspected, and the time for executing it was when the acute symptoms had subsided, that was to say, à froid. It was there, in his opinion, that consisted the great progress in the treatment of appendicitis. They knew to-day that that affection was subject to relapses, more or less frequent, and that the first attack was less grave than those that followed.

Consequently it was the imperative duty of the surgeon to propose the ablation of the appendix to subjects who had had their first attack, for the return to health was always incomplete, and the patient was consequently exposed to a serious relapse.

BLENORRHAGIA.

Menthol, 1 gr. Salicylic acid. ii gr. Phenic acid

Lactic acid
Essence of eucalyptus (iv gr.

Salicylate of methyl Resorcin, x gr.

Water, 3iv.

This formula is based on the principle that a mixture of several antiseptic agents is endowed with more energetic properties than one of those substances employed in strong doses.

Half a syringe is injected twice a day.

Germany.

[FROM OUR OWN COBRESPONDENT.]

BERLIN, March 10th, 1899.

SURGERY OF THE STOMACH IN CANCER AND ULCER. PROF. KOCHER, of Bern, whose experience in the surgery of these diseases is probably second to none in the world, gives (Deutsch. Med. Zeit., March 9th, 1899) an interesting account of the present state of this subject. The indications given by him for operation are practically those formulated by Leube at the Surgical Congress, 1897, adding, however, that it is also indicated in cases where violent pains and vomiting persist after a lengthened course of careful internal treatment. One should not wait until the patient has exhausted nearly all his strength by hæmorrhages or excessive digestive disturbances. Operation should be considered as a refuge, but not as a last refuge.

As regards the choice of operation, the author only recommends simple excision of ulcer when it is well circumscribed and surrounded by healthy structure. With simple pain and dyspepsia gastroenterostomy or pyloroplastique is sufficient, but when there is hæmorrhage partial resection is called for.

If there is suspicion of carcinoma—and there always must be when the patient is elderly and the pains have lasted long—laparotomy is indicated, even when there is no palpable tumour and the chemical composition of the gastric contents is not greatly altered. The earlier the operation the better are the prospects of permanent recovery, and with the small amount of danger associated with exploration, the operator has no need to reproach himself even when nothing is found, and the pain is discovered to be neuritic, especially as such pains are frequently surprisingly relieved by exploration.

How far the carcinoma has advanced still to justify operation must be judged by the individual case, but Prof. Kocher has seen cases where there were metastasis in the adjoining peritoneum, and with lymph tracts that could not be removed, when the disease thus left behind retrogressed after operation. The more widely an operator extends his indications for operation, the more unfavourable will be the results.

Resection with subsequent gastroduodenostomy has given the author the best results: complete closure of the wounds of the stomach and duodenum, and then implantation of the duodenal wall into the stomach, with silk (not catgut) sutures, and without Murphy's button, as when this is used there is no guarantee that it will be ultimately expelled.

He promises shortly an exhaustive report on his stomach operations, saying at present only so much, that on the basis of his own statistics, with resection and gastro-duodenostomy, he can promise with a probability bordering on certainty, a favourable result in all uncomplicated cases of carcinoma of the stomach.

ECLAMPSIA.

Dr. Carl Winkler has a paper on this subject in Virchow's Archiv. 154, 2, based on nine cases observed by him, in which a careful microscopic and histological examination was carried out. His main conclusion is that eclampsia is an intoxication of the organism with the products of tisgue change. The occurrence of the intoxication is connected with a serious change in the kidneys, which are anatomically considered as the one fixed point in the disease. The kidney disease is a glomerulo-nephritis, it manifests itself in swelling of the glomeruli, excessive fatty degeneration of the epithelium among them, the tortuous and straight canaliculi, exudadation into the lumen, and hæmorrhage into the parenchyma.

The glomerulo-nephritis may be an exaggeration of the physiological alteration of the kidneys that occurs during pregnancy or a recurring chronic nephritis. Here the grave symptoms are brought about by exacerbation of the disease and overburdening of the kidneys in the act of birth.

Along with these fundamental changes a series of others are observed, necrosis of the parencyhma of the liver, cell, emboli. &c. These changes are not all con-

stant, they are not characteristic of eclampsia, and to some extent they are results of the attacks of eclampsia or of the pregnancy itself.

LIMITATION OF ABDOMINAL SECTION BY ANTERIOR
KOLPOCELIOTOMY

Is the title of a work of 266 pages just published by A Duhrssen. The aim of the work is stated by the author to be "to help truth to its rights," but this may be said to be the aim of all books. I bring the book before the notice of your readers not because I endorse all the writer says but rather as an illustration of how things may be carried by an enthusiast. I would not minimise Duhrssen's deserts in the least, he has done as much as most men of his years for the advancement of his specialty, but one cannot help wondering sometimes whether with some people enthusiasm may not get the better of judgment.

In a tabular form he gives a review of 401 cases of vaginal abdominal section, 359 of them were vaginal fixation for retroflexion of the uterus, 35 vaginal fixations of the round ligaments, 6 vesical fixations for retroflexion of the uterus, 73 vaginal adnexa operations and operation on the uterus for anteflexion, 18 vaginal coliotomies for tubal pregnancy. In 16 further cases the attempted vaginal operation had to be completed through the anterior abdominal wall or by hysterectomy, 15 cases died, 2 of them belonging to the latter group. No death occurred in the group when simple retroflexion was reduced by vaginal fixation, and so far it seems a safer operation than that of shortening the round ligaments, but whether it is as effectual as a method of treatment time alone can show. What strikes one as remark able is the enormous number of vaginal cutting operations for the comparatively harmless and easily treated condition of retroflexion of the uterus. Evidently gynæcology is becoming even more and more surgical-As regards this operation the author himself thinks some excuse necessary, for he compares retrofletion with hernia without symptoms, and he asks whether any competent surgeon would advise a patient who suffers from hernia without symptoms to leave it alone.

He suggests that midwives should be instructed to direct all their patients to go to a doctor to be examined 14 days after their confinement. By doing so any post-partum retroflexion could be put right in good time. He is not in favour of the use of pessaries, which rarely lead to a cure of the condition.

After describing the indications for anterior vaginal coeliotomy afforded by various diseases of the uterus, adnexa and pregnancy, he describes the method of artificially inducing sterility by vaginal resection of the tubes. In this way he has operated on 26 women, and so far he has only met with one case that was not successful. He based his procedure on the standpoint that the introduction of artificial sterility is not only permitted, but demanded in the cause of humanity under certain circumstances and conditions, and in such cases vaginal resection is the most suitable way of bringing the condition about.

THE Plymouth Guardians have at length decided to build a new workhouse infirmary, and have opened up for consideration the question whether they shall not build a new workhouse as well.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 11th, 1899.

CAMPHOR AND PULMONARY TUBERCULOSIS. CAMPHOR has been employed to protect the person

against attacks of different diseases from early times, but has often been condemned in our more recent literature as a worthless agent for antiseptic purposes. Bruno-Alexander has been experimenting with camphor, and comes to the conclusion that it is a valuable drug in pulmonary tuberculosis. When administered subcutaneously he finds it to be an antihydrotic, antipyretic, and effectual in checking purulent discharges and sputa formation. It does not impair the digestion in phthisical cases, but on the contrary improves the appetite, while it reduces the hyper-reflex action and thus effectually checks the irritable cough that usually accompanies the disease. The oil of camphor must be administered in small doses of 0.1 to 0.2 of a cubic centimetre (Germ-Phar.) daily, which would contain about 0.01 to 0.02 of camphor.

This treatment should be applied without intermission for four or six weeks, when a pause of one or four weeks may intervene before recommencing. If the patient have no fever 0.3 to 0.5 cubic centimetres of the oleo-camphor (German Pharmacopœia) may be given for eight or fourteen days, when an interval of eight days should be made. These patients can often be given one cubic centimetre of camph.-equal to 0.1 gramme of camphor -at one dose daily. The treatment should be continued some time after improvement has been established. Hæmoptysis is no barrier to the use of the drug.

ERYSIPELAS AND METACRESOLANYTOL.

The therapeutic value of metacresolanytol in erysipelas seems, from Kölzer's experiments, to be that of a powerful antidote. Löffler drew attention to anytol and anytine some time ago as antidotes, but from more recent experiments the metacresolarytol appears from the evidence of Kölzer to be still more potent. He produced erysipelas artificially in the ears of guinea-pigs with streptococci and mouse septicæmia bacilli. When the florid inflammatory rash was induced, a quarter of a c.c. of a three per cent. solution was injected well into the cartilage with the best effect. The same result could be obtained by painting the surface every five minutes for two hours with a piece of cotton steeped in the solu-The control animals throughout proved to be still suffering from a dangerous virulent infection after all symptoms and danger had disappeared from the protected animals. He has treated five human beings with the drug, and obtained wonderful results. ing with the solution causes a brownish colouring with swelling of the skin. Further experience is necessary to confirm these results.

RECURRENT FEVER AND ANTI-SPIROCHETIC SERUM. Lowenthal, who has recently been devoting his attention to the subject of recurring fever, relates the result of 84 cases which he has treated with anti-spirochetic serum. On an average 18:45 c.c. of the serum was used. In the 84 treated 47 per cent. had no relapse, 37.3 per cent. had one relapse after injection, 131 per cent. had two relapses. Under ordinary treatment with drugs 12.8 per cent. had one paroxysm, 32.9 per cent. had two paroxysms, and 465 per cent. had three paroxysms

Once in 328 injections an abscess formed in the abdo-

The frequency and quality of the pulse suffered no alteration by the injections, while hepatic and splenic enlargement was rarely met with. In 131 injections a general rash with swelling of the joints and albuminuria with cylinders appeared twice. The so-called albuminuria febriles was temporary, and passed away after the serum treatment was stopped without leaving any bad effects.

The Operating Theatres.

HOSPITAL FOR WOMEN, SOHO SQUARE. DERMOID CYSTS OF THE OVARIES -Mr. S. OSBORN operated on a woman, æt. 38, who had been married nineteen years, having had four children, the last five years ago. The patient had noticed her abdomen getting bigger during the last eighteen months; at one time she thought she was pregnant. For the last five months she had a burning continuous pain in the hypogastrium, which was only relieved when she laid down. There were no pressure symptoms; the bowels acted well, and micturition was normal. For the last five months she had suffered from sickness, generally the first thing in the morning. The catamenia had been regular, profuse during the last eighteen months, lasting about six days and being accompanied by very little pain; there was no cedema of the feet. After examination a diagnosis was made of ovarian cyst, and it was decided to perform ovariotomy. Mr. Osborn pointed out the patient's sister had been operated on for ovariotomy some ten years previously at St. Thomas's Hospital. A median incision about 4 inches long was made and the abdomen opened. A cyst rather larger than a cricket ball was easily removed from the right side, and then a corresponding one from the opposite side, this last one being a little smaller than the first. Both the cysts shelled out easily. Both the pedicles were ligatured with Japanese thread, and the abdomen was closed without flushing as the cysts had been removed entire. The cyst on the right side contained matted hair, with hair also growing from the inner wall; the cyst on the left side was about the size of a tangerine orange, and contained some hair, but its contents consisted mostly of gelatinous material. Mr. Osborn said the interest of the case lay more especially in the fact of a dermoid ovarian cyst existing on both sides and the woman having had children. He pointed out that the hair in the larger cyst was matted together in a similar manner to the stuffing of a cricket ball, and that hair was also growing from the interior of the cyst wall. He considered, also, that an interesting point with regard to the case was the fact of the patient's sister having been operated

on for a similar complaint some years ago. It is satisfactory to record that the patient never had a bad symptom after the operation, and made an uninterrupted recovery.

Dr. Hogarth, in practice at Ilfracombe, was found dead in his rooms on March 9th, with a bottle containing poison by his side. He had only been in Ilfracombe about ten months, having for many years previously been in practice at Cheltenham. No motive can at present be attributed for the act.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 15, 1899.

THE GENERAL MEDICAL COUNCIL.

A MEETING of the Executive Committee of the Council was recently held at which several important matters were touched upon. The Committee had been entrusted by the Council with the conduct of an inquiry into the alleged illegal issue of certificates of proficiency in medicine, surgery, or midwifery, but the Committee decided to recommend that, as the Midwives Bill is now before Parliament, it should at present refrain from taking any action. As regards the certificates granted to spectacle makers it is obvious that the Council has no jurisdiction over opticians, but the Council would be prepared to consider any properly substantiated charge of improper conduct made against a registered medical practitioner in this connection, an intimation which we commend to the notice of those whom it may concern. The most interesting subject was that of the employment by medical men of unqualified dispensers, which had been brought to the notice of the Council by various communications. After discussing the subject the Committee arrived at the following halting and illogical conclusion-viz., that the Privy Council advised that while occasional accidents may arise from the employment by medical practitioners of careless or incompetent dispensers, the cases, in their opinion, are very rare, and the committee hold that probably the best protection is afforded to the public by the responsibility of the practitioner for the acts or defaults of the servants whom he employs. First of all, it must be apparent to everyone that the committee, in assuming that such accidents are very rare, is jumping to a conclusion. No data other than the published law and inquests reports are open to its members, and no

weight is given to the fact that in any case only fatal cases are likely to become public. Moreover, in the majority of instances, it must be easy for the practitioner to hush the matter up, a course which he has every inducement and every facility to adopt. A more straightforward way of dealing with this important question would be to state formally that the matter is not one which comes within the scope of the Council's jurisdiction, though none can question that if so minded the deliberate employment of incompetent dispensers might legally be declared by the Council to be inconsistent with the duty of the practitioner towards the public. We shall await with considerable interest the view taken by the Council of this recommendation.

We are pleased to see that a feeling is gaining ground in favour of reciprocity of practice as between Italian and English physicians. A letter has been received, via the Privy Council, from the Italian Ambassador, asking whether, without obtaining a fresh diploma, Italian physicians can exercise their profession in this country, or at least attend on foreigners resident in Great Britain, and whether, if the answer to this question be in the negative, Her Majesty's Government would be willing to grant permission to Italian physicians so to do if the Italian Government would grant similar privileges to English physicians residing in Italy. The Committee decided to inform the Privy Council that they would welcome such a recognition of English practitioners in Italy as would enable Her Majesty in Council under Section XVII. of the Medical Act, 1886, to extend similar privileges to Italian practitioners in this

A communication was read from the Home Office stating that fresh legislation would be required to alter existing arrangements in respect of the allocation of penalties incurred under the Medical Act, 1858, within the Metropolitan Police district, but the Home Secretary did not see his way, for the present at least, to introduce a Bill for the purpose.

The Russian Ambassador having asked to be furnished with information as to the law of this country in regard to the professional secrecy of medical practitioners, Mr. Muir Mackenzie was requested to formulate an opinion, from which it appears that on the question of violation of professional secrecy a medical man is in no more favoured. position than anyone else, and, further, that circumstances which, according to the custom of the medical profession, might be deemed to exonerate him from the imputation of improper violation of secrecy might, nevertheless, in a court of law, be deemed an insufficient justification. This oracular, but somewhat ambiguous, pronouncement does not throw much light on this very delicate and important question, but we hope next week to be able to find space for the full text of this opinion.

In respect of the identification of registered practitioners the Committee recommend that no application for the restoration of names of persons who have been removed from the Register shall be entertained unless it be accompanied by a Statutory

Declaration made by the applicant setting forth the facts of the case, and stating that he is the person originally registered, and by a certificate from a clergyman or magistrate or registered practitioner as to his identity. We are fain to confess that we doubt the trustworthiness of this precaution, which does not appear certain to offer complete security against personation. Among the other matters which came before the Committee was the promulgation of the conditions under which the documents, the property of the Council, shall be made accessible to members of the Council who may desire to take cognizance thereof. These are very fair, and will go far to undo the mischievous impression created by the ill-advised and arbitrary action of the President on a recent occasion.

An opinion which strikes one as curious was received from Mr. Muir Mackenzie to the effect that it would not be legal to add to the name of a practitioner registered in the list of colonial practitioners of a British qualification which he had obtained. We can only ask, if not, why not?

THE IRISH UNIVERSITY QUESTION.

ALTHOUGH the proposal to erect and endow a special Catholic University for Ireland is much too strongly redolent of religion and politics to be dealt with in an unsectarian medical journal, it appears to have so intimate a relation to higher medical education in Ireland that we desire to put before our readers a plain statement of the case which, indeed, is not accessible to the readers of Irish newspapers, every one of which is the exponent of and partisan of one or other politico-religious view. In August, 1850, fifty years ago save one, the Queen's University was established in Ireland, the principle of which was absolute unsectarianism. The teaching work of the University was provided for by the establishment of the three Queen's Colleges in Belfast, Cork, and Galway, the University itself being a nominis umbra which occupied an obscure office in Dublin Castle. From the first day of the inception of this system the Catholic Hierarchy, and the large population which followed their dictates, set themselves to "boycott" the Queen's Colleges on the ground that they were "godless," i.e., secular, and their efforts proved quite effectual, save in the case of Belfast, where the write of the Catholic Hierarchy do not run with as great authority as elsewhere. To emphasise this hostility to unsectarianism, the Catholic University as it now exists was opened on November 3rd, 1853, but it has carried on its functions, ever since, as a purely teaching institution, lacking Charter powers to confer degrees of any sort. On November 3rd, 1882, the Government of that day made a further effort to conciliate the Catholic Hierarchy by abolishing the Queen's University and substituting for it the Royal, an institution strongly flavoured with thorough-going Catholicity, but managed by a mixed Senate, in which the Belfast Nonconformist party have a potent voice. The "Royal" has, in the eighteen

years of its life, been excellently administered, and has preserved the standard of education in Ireland exceedingly well, but, after all, it is only an examining body, and does not teach anything, and-irredeemable sin-it is not purely and wholly Catholic in its constitution. It is enough to say that the Catholic Hierarchy, after more than half a century of effort to settle the University question in Irelandare just where they were, clamouring for a University which shall be under their control but supported out of the public funds. The question is, therefore, by their attitude, converted into one, simply, of denominationalism against secularism. They insist that the Catholic population cannot be expected, and ought not to be permitted, to study or graduate anywhere save in a Catholic sectarian University. The Protestant party on the other hand fight against denominationalism of any sort as being the setting up, for all time, of an impassable barrier between the religious parties in Ireland, and the consequent perpetuation of social and political rancour. The Government, if Mr. Balfour speaks its mind, wishes to conciliate the Hierarchy and, to that end, is trying to bribe off the opposition of the Northern Protestants, as he bought off the resistance of the landlords to the Local Government Bill, by promising money for the establishment of a special Belfast University, but the bait has not been jumped at as might have been expected.

Our readers may at once clear the ground for the consideration of this subject by getting it out of their heads that any one in Ireland, be his religion what it may, suffers from any real educational disability whatsoever. There is not alleged to be the slightest hindrance to any Irishman obtaining the best education on the cheapest terms or the best degrees which he may wish for, save a sentimental grievance which we admit is none the less, material-In the very heart of Trinity College, a Catholic student may compete for and win and enjoy every distinction and monetary advantage which one of other religion can aspire to, and, as far as we know, his social life is made as pleasant to him by his brother students as is possible. Nevertheless, the Catholic Hierarchy have justice for their complaint that a Catholic student in Trinity College breaths in an uncongenial "atmosphere," just such as a Protestant student, if permitted, would breath a Catholic æther at Maynooth. Indubitably Trinity College (which is the University of Dublin), is, for the Catholic, offensively Protestant in tone. It has a Protestant Chapel in its grand square, and a subsidised School of Divinity of the Church of Ireland, and it is governed by a Board of Fellows, and a Council of whom, we believe, not one is a Catholic, or, under existing circumstances, is likely to be. Clearly the straightforward, statesmanlike way out of the educational impasse would be to make the University of Dublin the National University, removing from it at one swoop, all these anomalies, reforming, with liberal hand, the constitution of the governing bodies and, in fact, making the University perfectly free to all comers without a suspicion of religious bias in

Digitized by GOOGLE

any one's favour. But this will not be done. The Catholic Hierarchy would not accept such settlement, because it would deprive them for ever of the grasp which they desire to retain on education in Ireland. The University itself would also resist, because the change would involve reform which, of all things, it dreads most, and therefore its Parliamentary representatives will vote a sectarian University when the time comes. The Government will, no doubt, do whatever is opportunist. It will throw Irish education to the strongest political party, just as it threw the vaccination question to the antivaccinationists. If Mr. Balfour finds that the Scotch and Welsh Nonconformists and the contingent of Protestants and Secularists in the House of Commons are too strong for him, he will find reasons to drop the subject, and the Catholic Hierarchy will be remitted to another quarter of a century of agitation and Trinity College to the same period of inertia.

THE SURGERY OF THE EPIPHYSES.

Among the manifold achievements of modern scientific medicine the more brilliant results have undoubtedly fallen to the lot of the surgeons. Indeed, it has been claimed with a not inconsiderable show of reason, that the days of the pure physician are numbered - that is to say, in other words, that he will be ousted by the surgical craftsman. Should that process of extinction occur it will undoubtedly also be hastened to no small extent by the raised standards of general health that stand like signal posts to mark the onward march of the sanitarian. Meanwhile, surgery itself is becoming yearly a more and more perfect art, with an increasingly accurate knowledge of details, and a wider application of general principles. Nowhere, probably, has the surgeon made greater strides of late than in the surgery of the epiphyses. Until lately all information upon this class of injury was of the scantiest and most meagre description, derived from the comparatively rare evidence afforded by operations and by museum specimens. Now, however, all that has been changed by the advent of the Rontgen method of diagnosis, which permits the surgeon to investigate with ease and accuracy every case of epiphyseal injury with which he may be confronted. The obscurity and the complex nature of traumatism of the kind are naturally great, a fact which is explained by the frequent combination of complete or partial separations with fractures of every possible kind and direction, both of the shaft and of the epiphyses themselves. The bulk of these injuries are inflicted during the age of growth, and date from the intra-uterine period up to about twenty-three years of age, the greater incidence being between the ages of twelve and eighteen. Keeping this age-incidence in view, the common occurrence of subsequent deformities will be readily understood, as by such injuries growth will be arrested, and the relations of joints altered by the various nutritional and anatomical changes that are entailed in and around long bones and joints. It

is only of recent years, however, that surgeons have begun to recognise the nature and the importance of these lesions, from causes doubtless nearly connected with the above - mentioned difficulty of obtaining direct evidence. Mr. John Poland, who has just published a classical monograph on the subject, puts the matter as follows:-" Even at the present day," he writes, "we see that there are very contradictory opinions with regard to these injuries; one surgeon detects them very frequently, while another never does so, or only admits that they are rarely met with. This difference of opinion has been due in part to the absence hitherto of direct examination in a large proportion of cases, and in part to the ease with which the epiphyseal separation may be confused with dislocation or fracture of the But the surgeon is in this end of the diaphysis." instance indebted to the marvellous discovery of Rontgen not only for diagnosis, but also for valuable indications as to the need of operative measures, and of the subsequent progress of the case. In the whole range of surgery there has been no one particular field in which the application of the new method of diagnosis has been attended by more brilliant and more immediate results. Moreover, it must be remembered that many other pathological conditions involving the epiphyses may be disclosed with equal directness and certainty. Mr. Poland has been the first to apply the Rontgen methods systematically and universally to the investigation of epiphyseal separations, and he has been erabled thereby to bring the labours of many years to a triumphant issue. Had the discovery of the Würzburg Professor resulted in no other practical gain to humanity than in this matter of the bony epiphyses, it would have vindicated its claim to a permanent niche in the Temple of Fame. Yet it is only a little over three years ago that the news of these wonderful rays ran like wildfire through the length and breadth of the scientific world. Despite of all that has since been done by workers in many directions, it seems likely that we have scarcely passed the threshold of the new art. Meanwhile, epiphyseal surgery has now been established, thanks chiefly to radiography, upon a sound and unassailable basis.

Aotes on Current Topics.

The Great Atropine Poisoning Case.

THE great sensation of the past week in Paris was the trial of a faithless spouse on a charge of having attempted to poison her husband by the administration of atropine. From a medical point of view the interest lies in the employment for criminal purposes of such a drug as atropine, and the difficulties which surrounded the diagnosis. Granting that no suspicion was entertained of the real nature of the symptoms, it is easy to imagine the number and variety of explanations suggested first by one doctor and then by another. Looking at the clinical tableau one wonders how it was that the

dilatation of the pupils, the dryness of the throat, and the peculiar kind of delirium, did not excite a suspicion on the part of the medical man in attendance of possible accidental poisoning. It is proverbially easy to be wise after the event, but the case shows how necessary it is for a medical man to take a broad grasp of the situation, and not to reject an hypothesis merely because it is improbable. The French are very proud of the strictness of the regulations in respect of the sale of poisons, but nothing is easier than to forge a prescription, and though no chemist would supply a chance customer with such a poison as cyanide of potassium, this can be obtained by the pound by going to a dealer in chemical products instead of to a pharmacy. In this case the doctor was only put on the scent by the accused frankly asking him to give her a prescription for six grains of atropine on the pretext that it was wanted to make a collyrium for a pet dog, an explanation which was not thought adequate. An analysis of the urine promptly settled the matter by revealing the presence of the alkaloid, and the removal of the patient to a home was followed by speedy recovery. Fortunately for society criminals of this class are generally blunderers, otherwise their discovery and conviction would often be a very difficult matter. It would, however, not be wise to congratulate ourselves over much in this connection, because, as only the blunderers are caught, it is possible that the cleverer rogues escape detection.

The Liverpool School of Tropical Diseases.

Two meetings of the Liverpool Association of Foreign Consuls have been held during the past few days for the purpose of explaining the objects and of promoting the interests of the proposed new school of tropical medicine. Prof. Boyce, at the request of the consuls present, briefly explained the intentions of the Council with regard to the school. There were to be four courses of lectures every year, to be given to qualified men, each course lasting two months. They had now a laboratory second to none in the world, and they had already appointed able men to the various branches, and within the next few days he anticipated that they would have acquired the services of a lecturer on tropical diseases, who, by his long experience in the tropics, and his scientific attainments would extend the usefulness of the school. There would also be on the staff a professor of zoology. Liverpool, he thought, was the best place in the world in which to establish such a school, as they had examples of the diseases brought from all parts of the world. They also intended giving a particular training to missionaries for districts where there were no medical men. would give them microscopes and encourage them in various ways. Then there would be the training of nurses, including black women, who would go back and help to fight these dreadful tropical diseases. From evidence furnished by the Medical Officer of Health, it appeared that the number of cases of malaria in Liverpool, 1897, was 242, of

beri beri, 14, of dysentery, 30, of tropical anemia, 39, scurvy, 1. In 1898 the number of malarial cases was 294, and the number increases from year to year. The material was therefore at their doors, and as the Royal Southern Hospital had placed a floor at the services of the committee, they had a ward and chemical laboratory wholly devoted to tropical cases. In less than ten days the ward and the laboratories would be ready, the one to receive patients, the other to investigate the condition of the blood and the excreta. Subsequently a resolution, proposed by Mr. A. L. Jones, was unanimously carried to the effect: "That this meeting of consuls expresses its appreciation of the great importance of the work undertaken by the Liverpool School of Tropical Diseases, and suggests that each consul bring the matter to the notice of his Government, and also of the medical profession and others interested," in such a way as may be best according to his judgment."

THE MEDICAL PRESS

The Plague.

THE latest reports from India are very disquieting. A far higher death-rate from plague in Bombay has once more created quite a panic. The recorded mortality for the week exceeded eighteen hundred. These were wholly among natives; nevertheless, the richer and better classes have taken fright, and have been leaving the city as quickly as possible. artisan classes are also following their example, so much so, that a serious commercial stagnation is looming in the distance. The death roll of this alarming visitation of plague has already exceeded two hundred thousand, while a very large number of natives secretly stole away from the city by night and have not since been heard of. latest reports from the Kolar Goldfields show that the plague continues to spread in spite of strenuous precautionary measures. The panic among coolies continues, and the Mysore mine presents a desolate appearance, owing to the exodus of miners. The Secretary of State for India has received a further telegram from the Viceroy to the effect: "That the hospital arrangements are excellent; evacuation and segregation being vigorously carried out; panic somewhat ceased, but at Mysore mine 1,000 out of 4,000 coolies have left." The outbreak at Nasik, a town of 25,000 inhabitants, 500 cases of plague occurred in the first epidemic visitation, and 200 in the second up to the present time. Nasik was probably infected from Igatpuri by human agency. The epidemic proved to be more fatal during the cold weather. The ward system adopted here has proved satisfactory. From Constantinople we learn that plague has broken out at Jeddah, and that the issue of strict sanitary regulations led to serious disturbances, which led to their withdrawal.

The Use of Colouring Agents in Food.

MARGARINE manufacturers profess to regard the threatened prohibition of colouring matter in margarine as a great hardship of the nature of an injustice seeing that no restriction is placed on the use thereof in preparing butter, &c., for the market. But the only object of colouring margarine is to increase its resemblance to butter, not perhaps exclusively for the purposes of fraudulent sale but because purchasers who affect this substitute for butter conceivably might not wish to be continually reminded that what they are eating is not butter. We can quite understand, too, that the proprietors of boarding-houses and eating-houses might be averse to flaunting the identity of this particular alimentary substance before the eyes of their guests and customers who might otherwise not notice the substitution. While Parliament is tinkering at food and drugs adulteration legislation would it not be well to take advantage of the opportunity to forbid the use of colouring agents in butter as well? Colour is not added merely because the public is supposed to have a decided taste for butter of a particular hue, but because inferior butter can thereby be made to resemble that of much higher quality. It follows that it is as much a fraud to use colour in butter as in margarine, and there is no obvious reason why it should not be treated as an adulteration.

Extension of Hospital Accommodation for Infectious Diseases in Liverpool.

At the instance of the Local Government Board. an inquiry was held at Liverpool on the 9th inst., before Mr. T. Thomson, M.D., barrister-at-law, respecting the application by the City Corporation for sanction to borrow the sums of £3,500 for the purchase of additional land in Fagakerly, an outlying village, and £20,000 for the erection of a smallpox hospital in the same village, and also £40,000 for the extension of the City Hospital East in Mill Lane, Old Swan. There was not the least difficulty, either on the part of Dr. Hope, Medical Officer of Health of the City of Liverpool, nor of those associated with him, in supporting the proposal, among whom was Dr. Clarke, Chairman of the Hospital Committee of the Liverpool Corporation, in making out a strong case, the hospital accommodation for infectious diseases, and for small-pox cases as a separate item, being far behind legal requirements. A large sum of money is required it is true, but it will certainly be cheaper to spend it in the way proposed than to allow matters to drift on as they are at present.

A Missing Drainage Tube.

DR. FINDLATER, of Edgware, had occasion as far back as the summer of 1895 to open an abscess for a barmaid, in dressing which he inserted a short drainage tube. The next day the tube had disappeared, and Dr. Findlater probed the wound without finding any trace of the missing appliance. The wound healed, but the arm remained more or less useless, and in 1898 a fresh swelling formed, was lanced, and gave exit to the long lost drainage tube. Thereupon the patient sued Dr. Findlater for damages on account of negligence. It transpired that the plaintiff herself thought the tube had been lost in the bedroom, and evidence was given by Mr. Stonham to the effect that the tube would not have been discovered

unless the sinus were laid open, a procedure which he considered would not have been justifiable under the circumstances. A verdict was returned in favour of the defendant. These cases, which may occur in the practice of the most careful and conscientious of practitioners, emphasise the desirability of becoming a member of the Medical Defence Union, because even a successfully defended case is, after all, a very costly affair for the unfortunate practitioner.

The Yorkshire College and Vivisection.

ENLIGHTENMENT upon the subject of vivisection moves only slowly among a certain class of otherwise estimable persons, and the truth of this has just been abundantly shown at Leeds. The Council of the Yorkshire College have for long recognised the inexpediency of not having a licence under the Vivisection Act for experiments upon animals, the application for such a licence having been delayed in consequence of the opposition of its chairman, Mr. Rawlinson Ford. The Medical School authorities in Leeds, however, recently again urged upon the Council the great need of having a licence, and, the request having been duly considered, it was at last agreed that permission should be given to apply to the Home Office for a licence under the Act. This action of the Council caused the resignation of the chairman, Mr. Ford. So far as Mr. Ford is concerned, he has, no doubt, by resigning his post, satisfied his conscience; but regret must be felt that he should have allowed his conscience to perturb him in this matter to the extent that it seems to have done. The late chairman of the Council earned a high reputation for the ability with which he discharged the duties of the post, and general regret has since been felt and expressed by his former colleagues that he should have deemed it necessary to retire. The wonder is that his connection with a body of scientific workers had not enlightened him upon the legitimacy and need of experimenting with Anti-vivisectionists cannot be called reasonable persons, so far as their fad is concerned, and therefore a broad-minded view of the matter was to have been expected of a chairman who, like Mr. Ford, had shown so much capacity in conducting the affairs of the Yorkshire College.

A New American Medical Editor.

THE Journal of the American Medical Association is one of the best and one of the most successful of the medical papers published in the United States, and it is now being edited by Dr. George H. Simmons, who was appointed to the vacancy created by the death of Dr. Hamilton. For English readers the Journal has only one drawback, and that is the prevailing irritating method of spelling which disfigures its There are some orthographic maniacs in Philadelphia and elsewhere who have left no stone unturned in order to diffuse this form of spelling among American editors. But the curious and most significant point is that, despite every persuasion, the New York medical journals have refused to follow any such lead. Another matter which claims attention is the remarkable inconsistencies of this American method of spelling. The plan is to "lop off" the "al" in adjectival words, such as anatomical, physiological and so forth. But we fail to see why the "al" should be allowed to remain in other words of the same kind. The following sentence will illustrate our meaning. "The case is really a gynecic [This word actually appeared in an American contemporary.] one. But doubt may be felt whether surgic treatment would be better than medic under the circumstances. The patient is obviously not strong in a physic sense, and probably, therefore, the most practic way of treating her would be first of all to try the effects of therapeutic measures." The new editor of the Journal of the American Medical Association has now the opportunity of purging the pages of this admirable publication from a new-fangled system of spelling English words which is both inconsistent, unnecessary, and irritating.

The Chelsea Hospital for Women Appointments.

THE current number of Truth calls attention to the fact that the Board of the Chelsea Hospital for Women recently passed a resolution to the effect that no general practitioner should in future be a member of the staff, and points out that since then two general practitioners have been appointed. One of the latter is now pathologist to the hospital, and this circumstance, our contemporary states, is the more remarkable inasmuch as in the advertisement declaring the post vacant it was expressly laid down that candidates "must be engaged in consulting practice only." We mention these facts mainly for the purpose of showing that it is evident the feeling against the Board in question is still alive, otherwise the editor of Truth would not have been asked to give publicity to these matters. Obviously, however, if the rule above mentioned has not been rescinded it should be adhered to, and the Board cannot be commended for their action in this matter. It does not appear to us to be a straightforward proceeding to say in an advertisement for a vacant post that a general practitioner is ineligible to compete and afterwards to appoint one.

Sanitarianism in Excelsis.

WHEN we deprecated, a couple of weeks since, the flights of fancy of the ultra-sanitarians as being the obstruction to the tuberculosis crusade which is most to be dreaded just now, and when we pictured the system which these enthusiasts advocate under which every one who coughs should be challenged by the sanitary police; investigated, if found guilty of consumption, notified; and promptly isolated, "willy-nilly," or, at the least, compelled to carry about a spit-cup in their pocket, and expectorate into it on all public occasions, some of our readers thought we were poking fun at the sanitarians. By no means. Some of these idealists go far beyond these proposals. A Dr. Knoff writes to the North-American Review to expound his suggestion. He wants in every State a commission of special examiners to examine each cough patient

to make domiciliary visits to the home and investigate all members of the family, to put the sanitary authority in motion for the renovation of the house, or even to burn it down if considered to be badly infected, and-to cap the edifice of coercion-to inquire into the financial ability of the patient, and, if he is not able to pay for his own maintenance in the consumption jail to which he is to be relegated, to compel the municipality to do so, paying, also, for the sustenance of the whole family. Say we not truly that such sanitary visionaries as Dr. Knoff, are the most dangerous enemies of any movement for the improvement of the public health?

Tuberculin as a Test Inoculation.

WE publish this week a short paper from a Melbourne correspondent, who apparently holds very strong views in respect of the use of tuberculin as a test for the presence of tuberculosis - views to which we are quite unable to subscribe, and which he himself does not appear to us to have justified or substantiated. Experience on a large scale, carefully scrutinised and discussed by highly competent persons, has shown conclusively that it is a trustworthy means of diagnosing latent and otherwise undiscoverable tuberculosis in cattle. We are not concerned with the value of tuberculin in therapeutics, though it would be rash to assume that because it proved a failure some years ago it can never render any service in this direction. Its activity in procur. ing the cicatrisation of local tuberculous lesions of the skin, e.g., lupus, proves beyond a doubt that under one set of circumstances, at any rate, it is possessed of curative properties. We welcome the news that the colonies are awakening to the importance of safeguarding their herds against contamination, one of the most important elements in the war against tuberculosis being the ability to isolate diseased animals before they have had time to infect their, as yet, uncontaminated fellows.

Is it Illegal?

An inquest was opened at Southport on the body of a man, æt. 26, who had died after taking a certain quack "fit remedy," sold by a "Dr." Fanyau. This nostrum, which is largely advertised, contains, we believe, bromide of nickel and arsenic, so that it is really a very poisonous preparation when taken in other than a very careful manner. The circumstance that appears to us to call for remark, is that the soi disant Dr. Fanyau had written to the deceased advising him as to the manner in which to carry out the treatment, and this seems to be sailing very close to an infringement of the privileges of the Apothecaries' Society. If any means could be found of inhibiting these pestilential foreign quacks from vending their nostrums in this country, the public would be the gainers. In any event it ought to be possible to prevent them from carrying on this kind of irregular medical practice under an unregistrable and possibly fictitious medical title.

The Presidency of the Royal College of Physicians, London.

SIE SAMUEL WILLES. President of the London College of Bhysicians, has decided not to seek reelection at the termination of his year of office on the 25th right. Consequently, great speculation is taking place at to the choice of his successor by the Fellows. The election will be held at the College on Monday the 27th, and although several names are now being discussed in connection with the post, nothing approaching certainty is known. Sir William Broadbent, of course, is mentioned, and we should not be surprised if he were to be ultimately chosen by the Fellows.

Stillborn Children.

A PETITION is being drawn up by the "British Institute of Undertakers" in favour of legislation, with the object of regulating the interment of infants alleged to be stillborn. This is an admitted scandal, and one which calls urgently for remedial measures. It is thought that the petition would gain in weight if it were endorsed by the medical profession, and we are requested by the secretary of the British Institute of Undertakers to solicit adhesions thereto, but we must confess to a distaste for any combined action of this character, and if a medical petition be really considered likely to further the object which we all have in view there is no reason why one should not be organised as and from the profession.

The Government Adulteration Bill.

This project of legislation is now denounced in every quarter—except by the adulterators—as a miserable pusillanimous makeshift. It makes some right improvements in the method of prosecuting—but, in other respects, perpetuates most of the short-comings of the present law.

The Palmar Sign of Typhoid Fever.

What has been called the palmar sign of typhoid fever is a yellowness of the palms of the hands and soles of the feet. This change in colour is said to be more marked in proportion as the integument is thickened by toil, but is still present when the skin is thin. The change comes on in the early days of the disease, and lasts until the end, disappearing in convalescence. The yellowness has been attributed to feeble circulation by which the subcutaneous fat becomes apparent through the skin. We are not aware that this symptom has been looked for or observed in this country. Probably not.

The Peculiar People.

THE firm attitude of the judiciary which has fastened upon the members of this misguided sect the responsibility—common to all the world—of providing for the medical care of their families, seems to be producing its effect. It is stated that the elders of that cult are deliberating as to whether they shall give way, at least, to the extent of permitting their disciples, if they wish, to call in medical aid for their sick children. Should this course be adopted it will

at least deprive these fanatics of any legitimate-excuse for allowing their children to die of neglect.

Astragalectomy.

This little-known operation of removal of the astragalus, should have a future before it in the relief of various forms of equine talipes. The bone in question is removed by a curved incision across the upper surface of the arch of the foot from a spot in front of the peroneus longus, to the tibialis anticus The joint is opened, and the bone dissected out, the extensor tendons of the toes, and the achillestendon divided; the foot brought into a right-angled position and fixed for six weeks or more in a plasterof-paris splint. The malleoli soon adapt themselves to the tarsal bone, and a new joint is established, which is almost as useful as the ordinary ankle-joint. The operation is not altogether easy, but its results are most satisfactory, and it has the great advantage that it may be applied in the case of adults, when the chance of relief by other measures is of the scantiest. This brilliant illustration of modern joint surgery, which, by the way, appears to be more practised in America than in our own country, has been rendered possible only by the methods of aseptic surgery. With its aid the orthopædic sur geon will be enabled to undertake with confidence the treatment of a common deformity.

Salaries of Medical Officers of Health.

THE rate of remuneration adopted by the various authorities of the United Kingdom as regards their Medical Officers of Health may be described as arbitrary and chaotic. In one place we find a first-class man doing a great amount of work at a miserable salary, while in another a less able official draws an extravagant sum in return for the services of a few spare hours. Of late years there can be no doubt that a considerable change has taken place generally in the attitude of sanitary authorities towards their medical officers. The advance of democratic opinions, for example, has made local administrators far more exacting in their demand for actual routine and personal work. Their tendency on the whole has been to employ "whole-time" men as apart from the hybrid "half-timer," who undertakes to discharge in his own person the conflicting duties of general practitioner, and of a medical officership of Clearly a standard is wanted in these health. matters, not only as regards salary, but also to settle the important particulars of the duties to be performed, and the amount of time to be given to the service. An equalisation of this kind would be of inestimable value in many directions, and might engage the attention of the Local Government Board with advantage. At present many authorities having vast and teeming populations under their control pay their medical officers a wretched and inadequate dole. Some day the growing national wisdom will doubtless recognise that money sunk in public health improvement is a prudent investment.

The Mortality among the American Troops During the Late War.

Some significant figures dealing with the mortality among the American troops arising out of the late Hispano-American war, were cabled to this country through Reuter's Agency last week. The figures in question are taken from the reports submitted to the Adjutant-General of the American forces, and show that between May 1st. 1898, and February 18th of this year the following deaths occurred among the American troops in Cuba, Porto Rico, and the Philippines:-Killed in action, 329; died of wounds, 125; died of disease, 5,277. The enormous disproportion of deaths under the latter heading at once claims attention. The figures plainly show that the Spaniards were quite correct in believing that they would have a firm ally in disease, in the contest with their opponents, and, possibly, unless the campaign had not been carried on with that brilliant rapidity, which the world now knows of and has acknowledged, the Americans might have found their task an exceedingly more onerous one, in the face of such a foe, than ultimately proved to be the case. Admitting, however, all the difficulties encountered in fighting against the unhealthy climates in the seat of war, it is still, neverthless, startling that such an enormous number of the American troops should have died of disease. earlier days, perhaps a catastrophe of this nature might have been anticipated. But we are living in modern times, and thus irresistibly the question arises, was everything done to prevent the inroads of disease which modern science and organisation could suggest?

Gout and Intellectuality.

HORACE, Leibnitz, Erasmus, Franklin, Milton, and Darwin, we learn, were sufferers from gout, that aristocratic but disobliging malady. Tiberius and Louis XI. of France were rheumatic, while Michael Angelo. Calvin, Montaigne, Colbert, Louvois, Buffon, and Désangiers—to mention but a few—were the victims of gravel. This enumeration would give a high idea of the intellectuality associated with the gouty diathesis; but to balance accounts we ought to mention a number of political and social eminences whose intellectual status would prove that gout is not necessarily, or even generally, allied with a high order of intellect. On the whole, it is safer to assume that gout and intellect are not incompatible, but that they can, and do, exist separately. Each gouty sufferer can thus decide for himself or herself whether gout is complicated by excessive intellectuality or the reverse, though we do not undertake to accept the werdict without cavil.

An Exhibition of Antique Surgical Instruments.

Nor one of the least interesting sections of the forthcoming Paris Exhibition will be the collection of antique surgical instruments. Appeal is now being made to collectors, museum authorities, and all possessors of rare or unique surgical instruments

and appliances for a loan of their specimens. Properly arranged and catalogued such an exhibition would have not only an instructive but an historical value, and would be worthy of some permanent record. We wish success to this enterprise, for nothing of the kind that we know of has ever been attempted before.

Alleged Malpraxis.

An action was tried a few days since in which a lad who had been injured in a street accident claimed damages against Mr. Zebulon Mennell, a Notting Hill practitioner, for having omitted to discover until some time after the accident, that the plaintiff's leg was broken. The defence was that there were surgical reasons for not putting the leg in splints at an earlier date, and this view was corroborated by Mr. Pitts and Mr. Ballance, with the result that a verdict was returned in favour of the defendant.

Extension of the Medical Acts to the Isle of Man.

THE necessity for some means of differentiating between qualified practitioners and quacks has been severely felt in the Isle of Man, to which bailiewick the Medical Acts have never been extended. To provide such means a Bill will be introduced to-day into the Manx Legislature to provide for the island such safeguards—inefficient though they be—as are provided in the mother country.

Typhoid Fever in Philadelphia.

An epidemic of typhoid fever on a large scale has broken out at Philadelphia, and the number of victims already exceeds two thousand. The case mortality is high, as it usually is at the commencement of an epidemic. The occurrence is attributed to pollution of the tributaries of the river from which the city draws its water supply.

A DAILY paper announces that "one of our most most distinguished medical baronets has been lying seriously ill for a month," and comments upon the fact that not a word has been published on the subject in deference to the express wish of the patient. Under the circumstances it would ill become us to lift the veil of anonymity, though, as medical baronets are not as thick as leaves in the valley of Valombrosa, it cannot be difficult to read between the lines.

Surgeon-Major Quinton, who retired from the Army Medical Service in 1884 after prolonged service in India, was found dead in a field near his house at Kings Teignton, Devon. The cause of death had not transpired at the time of going to press.

PERSONAL.

Dr. George H. Simmons, of Lincoln, Neb., has been appointed editor of the *Journal* of the American Medical Association,

Mr. Chamberlain will take the chair at a dinner in aid of the proposed School for Tropical Medicine on May 10th, next.

PROF. KOCH has written expressing his regret at his inability to be present at the Inaugural Dinner of the Liverpool School of Tropical Diseases.

Mr. Frederick Treves, Consulting Surgeon to the London Hospital, has been appointed an Emeritus Professor of Surgery to the hospital.

Dr. G. A. Maconachie, late Principal of the Grant Medical College of Bombay, has been offered the Lectureship on Tropical Medicine at the University of Aberdeen.

THE Khalifa is reported to be suffering from leprosy' indeed, there is every reason to believe that the symptoms of the disease are well marked, sufficiently so for it to be necessary to wear a veil.

SIR WILLIAM TURNER, President of the General Medical Council has been chosen as the President-elect of the British Association, which will meet in Bradford in the course of the summer.

Dr. G. A. Girson, of Edinburgh, has accepted the appointment of Inspector of the examination of the Apothecaries' Hall, Dublin, and Dr. Church has accepted that of Visitor for the same examination.

DE. FREDERICK HETLEY, a former student of the Middlesex Hospital, has contributed the sum of £1,000 to perpetuate the "Hetley Clinical Prize," in the Medical School, of £25 per annum founded in 1884.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE ROYAL MEDICAL SOCIETY'S DINNEE.—A large and representative gathering met on Friday last week at the annual dinner of the aucient Royal Medical Society of Edinburgh to meet Sir William Priestley, member of Parliament for the Universities of Edinburgh and Glasgow, the guest of the evening. The senior president of the Society, Mr. R. F. McNair Scott, officiated as chairman, supported by numbers of former members and presidents. The number of well-known names of men present, who once had filled the presidential chair in the Society, emphasised the prescience displayed by the various generations of members in electing them to this office Among those present were Sir William Gardiner, of. Glasgow, Professors Chiene and Simpson, Sir H. Littlejohn, C. Brown, Cossar Ewart, and Hunter Stewart; Drs. McMarin, Bury, Beatson, Allan Jamieson, Noël Paton, &c.

Paton, &c.

The Vacant Edinburgh Chair of Physiology.—
The election by the Patrons of the Chair of Physiology in the University of Edinburgh, the Board of Curators, seven in number—four nominated by the Town Council of Edinburgh, three by the University Court—will not take place until after May 20th next, so that candidates will have a more prolonged breathing-space than usual, and a longer time during which to canvass. Dr. Noël Paton, Professors Schæfer, Stirling, and Weymouth Reid, and Dr. Carlier are the names of those who up to now have shown signs of an intention to apply. The post will be worth about £1.400 in the future.

GLASGOW UNIVERSITY MEDICO-CHIBURIGICAL SOCIATY.

—The following office-bearers have been elected for Sessions 1899-1900 :—Honorary President, Professor Stockman; President, Mr. E. P. Cathcart; Vice-President, Mr. James Davidson, M.A.; Demonstrator, Mr. Thomas Richmond; Corresponding Secretary, Mr.

Matthew Aikman, M.A.; Minute Secretary, Mr. John Muir; Treasurer, Mr. Alexander Fraser, M.A.; Librarian, Mr. A. M. Pollook,

Manchester.

[FROM OUR OWN CORRESPONDENT.]

MEDICAL SCHOOL.—Considerable changes in the teaching staff are likely to occur during the present year. An aural surgeon and an additional assistant surgeon are to be appointed to the Royal Infirmary immediately. Dr. Milligan and Messrs. Cox and Larmuth are candidates for the former post, while for the latter it is understood that the following gentlemen are applying:—Messrs. Collier, Pomfret, Smith, Platt, and Montgomery. Next year two vacancies on the surgical staff are likely to occur. The Senior Physician, it is rumoured, intends to resign this summer. At the College, Professor Delépine is seeking to secure the Chair in Pathology at Glasgow.

TUBERCULOSIS.—Much interest continues to be taken in the "campaign" against tuberculosis. The Hospital for Consumption is about to start the working of the Liegehallen system. Mr. W. T. Crossley, a philanthropic citizen, has offered to erect an institution containing 100 beds if the city will guarantee something like three to four thousand pounds annually to support them. Dr. Ransome has been advocating the destruction of the many "tubercle nests," as he rightly calls them, in the crowded parts of the city.

MEASLES.—The School Board authorities have been expressing disapproval of the action of the Sanitary Committee in closing schools when the cases exceed 10 per cent. of the average attendance. They show that this is a much more stringent practice than is carried on elsewhere. It is to be hoped there may be no clashing between the Medical Officer of Health and the School Board, but mutual forbearance may be necessary.

INEBBIETY.—Manchester has long taken a practical interest in the inebriate class. One of the most successful of the retreats for women is maintained by some of the citizens. The following statistics compiled by the chief constable of the city have important bearing on the new Act:—The tabulated statement shows the number of persons convicted in towns in the Salford hundred of drunkenness or of offences mentioned in the first schedule to the Inebriates Act, 1898, and amenable under Section 2, for the three years ended December 31st, 1898. In the year 1898, it appears, there were convicted in Manchester 13 males and 72 females; in 1897, 16 males and 76 females; in 1896, 11 males and 65 females. In Salford there were convicted, in 1898, 18 males and 19 females; in 1897, 8 males and 10 females; in 1896, 13 males and 12 females.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday evening last (March 13th) was devoted to the reading of, and the discussion upon, a paper by Mr. John Langton on "The Radical Opera-tion for Inguinal Hernia—And Afterwards." After sketching the history of surgical attempts to deal with this disabling infirmity and the various modifications of practice and innovations of principle that had from time to time been introduced the author stated his preference for the operation which aimed at the reconstruction of the canal with transplantation of the vas deferens and its vessels to the upper angle of the incision so as to form a new inner ring. He insisted on the importance of a month's rest in the recumbent position after operation, and then proceeded to discuss the frequency and causes of suppuration after operation. At Bart's the proportion of suppurative cases had been about 16 per cent. At this institution the mortality in about 650 cases had been only two, and death was due in these, in one to septic pneumonia and in the other to scarlet fever. He remarked on the great preponderance of male over female patients—9,900 males against 870 females—at the City of London Truss Society, the reason for which he discussed. He approved of the use of a truss after operation, remarking that the patients who applied for relief by reasen of failure of the operation were persons who had been advised not to wear a truss at all, or had only done so for a short time. Operation was contra-indicated (1) under six years of age. (2) in presence of organic disease, (3) when the hernia was so large that the abdomen could not retain it under moderate pressure. (4) in very old retionts (5) with small harning sure. (4) in very old patients, (5) with small hernise when the abdominal walls were unusually weak, and (6) in septic peritonitis after strangulation. He commented on the extreme, even insuperable difficulty of ascertaining the ultimate results of the operation in hospital practice, but gave figures from which it might be inferred that the total number of failures must be considerable. In private practice the results were more encouraging, probably about 80 per cent. being successful.

The President (Mr. Edmund Owen) objected to the expression "radical cure," preferring to style it the operation for radical cure. He urged that unless the infant were well looked after it might be necessary to operate under six years of age. He himself operated as

young as three.

Mr. STANLEY BOYD entered very fully into the subject, insisting on the importance of leaving the peritoneum smooth and tense, and of rearranging the muscular arches in the manner met with in nature. In the event of suppuration he advocated removing some of the outer stitches, passing through the internal oblique, and placing a drainage tube close to the neck of the sac. He himself had fixed three as the limit of age in children. It was not his practice to recommend the us- of a truss after operation.

Mr. Osborn pointed out that in a young child the use of a truss would often dispense with the necessity for an operation. He approved of the recommendation to use a truss after operation, though this often disappointed patients who had looked forward to being enabled to dispense with its use.

Mr. Langton replied, pointing out that before puberty and after the menopause, inguinal hernia was the rule, and femoral hernia, when it occurred, usually did so during the child-bearing period, though even then 99 per cent. of herniæ in pregnant women were inguinal and not femoral.

Barliamentary Aews.

NOTIFICATION OF INFECTIOUS DISEASES -Sir Francis Powell has introduced a Bill, having for object to extend the Act of 1898 so as to make its application general throughout the country. Unless opposition from some unexpected quarter is manifested, there is great hope of this useful measure becoming law in the near future.

THE RIVERS POLLUTION BILL, which came on for discussion last week, was favourably received by the Government, but at the last moment it was "talked out" by one Jackson, the member for Leeds, so that for one more year, the sixth in succession, this very necessary piece of legislation fails to become law.

THE CONSTRUCTIVE MUEDER BILL is set down for discussion to day (Wednesday). It is very unlikely that any serious objection will be offered to a measure which

proposes to abolish a judicial farce which has shocked the minds of all thinking people.

DISEASE IN THE ARMY —Major Rasch asked the Secretary of State for India whether, in view of the facts stated in the Army Medical Report of 1897 that the number of admissions to hospital for venereal disease per 1,000 was 507, only 3 per cent. less than in 1896, and that the number invalided to England in 1897 was 662, an increase of 183 over the previous year, the Government would consider the advisability of permitting the Indian Government to take such measures as they might think fit for the detection of diseased persons of both sexes, and to detain such persons in hospital until cured; and whether the Government had received any reports as to the effectiveness or otherwise of the new canton-ment rules enforced in 1889. Lord G. Hamilton, in reply, said the statement related to troops in cantonments only. Including those on field service, the admission rate for venereal disease was 485 per 1,000 in 1897 against 511 in 1896, a reduction of 26 per thousand. new cantonment rules were not brought into operation until towards the end of 1897, and could not be expected to have much effect in lowering the ratio for the whole year. No report has yet been received as to their effectiveness or otherwise; and until the results of their working have been ascertained he did not propose to take any further action. The returns for 1898, so far as they were known, were very encouraging, and showed a considerable further decrease.

As might have been expected, a block has been put by Mr. Ascroft against the Bill which proposes to repeal the Conscientious Objector's Clause of the Anti-Vaccination Act of last year. This opposition does not affect the chance of passing the Bill, inasmuch as, with the Govern-

ment against it, it had no chance.

Laboratory Aotes.

LITHIATED JOHANNIS WATER.

It has been a desideratum to find a natural mineral water suitable in its composition for regular and con-tinuous use, and containing a definite and adequate proportion of a salt of lithium. This is exactly what we now have in "Lithiated Johannis." The proprietors of this spring have had the very happy idea of adding, under the most careful and skilled supervision, one grain of lithium bicarbonate to each small bottle of Johannis. We have examined samples, and find on analysis that the proportion of lithia contained is as stated on the label, viz., 1 grain of bicarbonate of lithia per bottle of 360 c.c. This proportion is one which may be safely commended for regular and general use. This is a point of some importance, because the much larger proportion of lithia contained in the B P. solution renders its habi-

tual use as a table water quite inadmissible.

In lithiated Johannis the drug is exhibited in an agreeable and convenient form, and in doses which can under no conceivable circumstances become excessive. So that we now have a natural mineral water of extremely advantageous composition containing just that amount of a salt of lithium which experience has shown to be

best adapted for regular and continuous use.

PEPTARNIS.

[Prepared by the Liebig's Extract of Meat Company, Limited.]

The sample on analysis yielded the following results:— Proteids (or nitrogenous matter) 53.0 Extractive matter... 6.0 \mathbf{Water} 33.0 ... Mineral matter (phosphates, &c.) 80

The above results show this extract to be of high quality, in particular the amount of mineral matter is satisfactory as showing that the article is not overloaded with salt.

THYROGLANDIN.

MESSES. EVANS and Co., of Liverpool, have submitted to us samples of Stanford's "Thyroglandin," a standardised product of the thyroid gland, prepared, we are assured, under conditions which preserve the active principles intent under the Percental Process of Marie Co. ciples intact, under the Patented Process of Mr. E. C. C. Stanford, F.C.S. It is claimed to represent five times the strength of the raw gland, and to be free from any tendency to undergo decomposition. The sample before us is a light brown powder, non-hygroscopic and free from any appreciable odour. The powder is also put up in pill form, pearl-coated, each pill containing one grain of thyroglandin. A product of this high standard is obviously in every way preferable to the B.P. preparations, which is simply the gland freed from fat, dried and powdered, and in which the characteristic odour of de composition is soon manifested. The activity of "Thyroglandin" has been experimentally tested, with uniformly satisfactory results, by Dr. Wm. MacLennan, of the University of Glasgow, who made use of it in a number of cases either for the relief of symptoms of myxedema or for the reduction of pronounced obesity. This observer attributes the therapeutical activity of the product to its containing iodoglobulin and thyroiodin in the form and in the proportion in which they exist in the gland, and to the absence of any injurious impurities of glandular origin.

THE MEDICAL PRESS.

Obituarv.

DR. FRANCIS N. MACNAMARA.

THE death is announced of Dr. Francis N. Macnamara, late of the Indian Medical Service. After a brilliant career at King's College, says the Times, he obtained, in 1853, an appointment to India, and, having particularly distinguished himself in chemical science, was at the early age of 22 appointed by the court of directors of the East India Company Professor of Chemistry at the Calcutta Medical College, to which was united the office of Chemical Examiner to the Government of India. In that capacity he devoted much time and skill to detecting in water the germs of cholers. By analysing various specimens of water from different parts of the country he was enabled to identify disease with the presence of impurities, and the necessary precautions were taken under his advice, though considerable prejudice and opposition had to be overcome. In conjunction with his brother, Charles Macnamara, he raised the question of supplying pure water to Calcutta, a work which was subsequently accomplished. Dr. Macnamara attracted to him the native students, by whom he was greatly respected and beloved, and from whom, on leaving India, he received sincere marks of esteem. He was as modest and retiring as he was earnest and persevering, and public notice scarcely followed his successful efforts. Upon his return to England after leaving the service, he was appointed by the Secretary of State Examiner of Medical Stores at the India Office. He was about to mencal Stores at the India Omce. He was about to relinquish this appointment when death overtook him, on the 5th inst., at the age of 67. Dr. Macnamara was the author of "Climate and Medical Topography in their Relation to the Disease Distribution of the Himalayan and sub-Himalayan Districts of British India" (Longmans, 1880), and contributed articles on "Goitre" to "Davidson's Hygiene and Diseases of Warm Cli-mates"; on "Pathological Chemistry" to the "Indian Annals of Medicine"; on "Abscess of the Liver" and other papers to the Indian Medical Gazette.

ME. HENEY BUTLER, M.R.C.S., Bradford, died on Wednesday last, at the early age of 35, from blood-poisoning, resulting from a prick from a safety-pin while applying a dressing. He was formerly on the staff of the Leeds Infirmary.

Correspondence.

We do not hold ourselves responsible for the opinions of our

THE HOSPITAL FUND "HAT" AGAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—It is gratifying to note that there is, at least, one weekly exponent-of-medical opinion which has the courage to protest, in the name of the profession, against the shameless flunkeyism of those who have dragged the name and rank of the Prince of Wales through the mire in order to make the Hospital Fund fashionable. His Royal Highness, in his proverbial good nature, was per-suaded—first, to start the Fund without due inquiry as to whether the hospitals deserve or require more money than they have; second, when the monied public showed their distrust of hospital administration by standing severely aloof, the Prince was induced to countenance the issue of stamps bearing his impress, and the organ-

ised importunity of Society people and school boys to huy and preserve them-to remind them, let us hope, in future, of what fools and toadies they once were; third, His Royal Highness is now again pressed into the begging service as the patron of a sham order of knights errant, who are to purchase, by a small donation, the privilege of calling themselves dames, or members or whatnot of the "League of Mercy," pose as philanthropic associates of royalty, and figure about with a pretty little decoration, pinned on their dress or perhaps, in a neat and becoming distinctive dress.

It is Mr. Editor very pleasant to observe that the

It is, Mr. Editor, very pleasant to observe that the feeling of the general public disapproves of this form of mendicancy, and that it declines to listen to the blandishments of the Fund wirepullers until the prevalent distinction of the rund wirepuliers that the prevalent suspicion that London hospitals neither merit nor need additional subsidy is set at rest. Even if it were possible to satisfy them of this, the method of importunity would be distasteful. His Royal Highness's advisers would be distasterul. His Royal Highness's advisers have misconceived the motives of the great body of monied philanthropists, and, gauging public sentiment by their own, have appealed to the weaknesses of human nature among the upper classes. They know that the Society would be's are willing to pay anything to be in the fashion, and if hospital benevolence is the correct thing they would just as soon have that sort of fashion as any other. They know that such people will go any distance to preserve their connection with the Society craze by buying stamps and little medallions which they can afterwards show admiring friends and by preserving newspaper reports in which their names are mentioned as attending some meeting at which the Prince of Wales presided—coached by medical toadies and supported by Duchesses and other leaders of fashion. The Fund wirepullers knew the money value of such incentives, and they have worked them—to use a vulgar phrase—'for all they are worth." But they forgot that in resorting to such methods and in refusing to allow any questions to be asked as to where the hospital money goes to, they have disgusted the infinitely more valuable *clientsle* of wealthy philanthropists who care nothing at all about "Sassiety," and who—as business men—are accustomed to look into an investment in philanthropy or anything else before they make it.

There is, as you say, Mr. Editor, but one way of recovering the lost confidence of this class, and that is, to cease all this foolery of stamps, medallions, and empty titles and make a clean breast and a root-and-branch reform of the abuses and maladministration of hospital incomes. With infinite respect and humility I suggest to his Royal Highness that he will do well not to continue his patronage of the begging movement until this is done.

I am Sir, yours truly, THE YOUNG MAN FROM THE COUNTRY.

Medical Rews.

Sixth International Otological Congress, 1899.

THE Hon. General Secretary asks us to publish the following as the latest arrangements. The Congress is to be held in London from August 8th to 12th, under the presidency of Dr. Urban Pritchard. The British Organisation Committee, which numbers over seventy members from Great Britain and the Colonies, has Mr. A. E. Cumberbatch for its treasurer, and Mr. Cresswell Baber for Secretary-General. It has also appointed the following sub-committees, viz. :

1. Reception:-Vice-chairman, Mr. Field; Hon. Sec. Mr. R. Lake.

2. Excursion.—Vice-chairman, Dr. Dundas Grant; Hon. Sec., Mr. P. Macleod Yearsley.
3. Dinner.—Vice-chairman, Mr. Mark Hovell; Hon.

Sec., Mr. L. A. Lawrence.
4. Museum. - Vice-chairman, Mr. C. A. Ballance; Hon.

Sec., Mr. Arthur H. Cheatle. The president elect is chairman of all the sub-commit-ees. The meeting will be held at the Examination Hall of the Royal College of Physicians of London, and Royal College of Surgeons of England, and the following details

Digitized by Google

沙野田口大口

have been arranged:—On Monday evening, August 7th, a preliminary reception will be held by the president-elect. On August 8th, 9th, 10th, 11th, the Congress will be in session, and will be followed on Saturday, August 12th, by an excursion for members and their lady friends. The official languages of the Congress are English, French, German, and Italian. The subscription, to include a copy of the transactions, is fixed at 21, to be paid to the treasurer, Mr. A. E. Cumberbatch, 80, Portland Place, London, W, before the opening of the Congress. The subject chosen for special discussion is "Indications for Opening the Mastoid in Chronic Suppurative Otitis Media," which will be introduced by Prof. W. MacEwen, of Glasgow; Dr. H. Knapp, of New York; Dr. Luc, of Paris; and Prof. Politzer, of Vienna A Museum of Specimens and Instruments relating to Otology, shown by members, will be held during the meeting. Communications regarding the museum should be addressed to Mr. A. H. Cheatle, 117, Harley Street, London, W.

Intending members of the Congress are requested to send in their names to the Hon. Sec. Gen. as soon as possible, and in any case not later than May 1st. Titles of communications together with a short abstract of the same, to be sent to the Hon. Sec. Gen. by the same date. According to the regulations of the Congress no papers shall exceed fifteen minutes in reading, therefore all long communications should be read in abstract.

The Manchester Committee of the David Lewis Trust have purchased Sandlebridge Estate, near Knutsford, for the purpose of turning it into a colony for epileptics. The estate is 450 acres in extent. The colony will consist of villas with gardens, a social hall, and administrative buildings, and the land will be sufficient to find employment for the patients, who are to be treated after the German method. Insane or feeble-minded cases will not be taken, and there is to be an endowment for the admission of some patients free of charge.

Medical Practice in the I-le of Man.

The English Medical Acts do not extend to the Isle of Man, and as an outcome of the recent agitation in the island, a Bill will, on Wednesday next, be introduced into the Manx Legislative Council, providing that only persons registered under the Imperial Medical Acts can sue for or recover fees for medical attendance, and only registered persons can be appointed to public medical positions. The penalty for pretending to be registered practitioners is a fine not exceeding twenty pounds.

DR. ARTHUR DAVID WHITE, news of whose death has only just come from Tangier, was the oldest graduate in medicine on the books of Pembroke College, Cambridge. He graduated Bachelor in 1842, Licentiate in 1844, and Doctor of Medicine in 1848. The doctor was eighty-three years old.

The annual meeting of the Asylum Workers' Association will take place on Monday, the 27th inst., at 4.30 pm., at the rooms of the Medical Society of London, 11, 'handos Street, under the presidency of Sir Jas. Crichton Browne, M.D., F.R.S.

Medico-Psychological Association.

The next examination for the certificate in nursing and attending on the insane will be held on Monday, May 1st. Candidates should obtain from the Registrar (Dr. Spence, Burntwood Asylum, near Lichfield) a schedule to be filled up, signed, and returned to him at least four weeks before the date of the examination. Monday, April 3rd, will be the last day upon which, according to the rules, candidates can enter their names for the May examination.

Mr. M'Ardle's Address.

The Registrar of the Royal College of Surgeons in Ireland requests us to insert the following: Mr. Cameron's History of the College, page 187, the author says:—"From their foundation to the present time the College, in at least their corporate capacity have never exhibited religious or political intolerance. Although a large majority of the members have always professed the magistrates in these cases.

Protestant religion, the Reman Catholic minority have never been deprived of their fair proportion of the honours and emoluments in the power of the College to bestow. At a time when the municipal corporations and many public boards rarely appointed a Roman Catholic to any office of honour or profit, the College of Surgeons elected Roman Catholics to be their presidents and professors — Williams Dease (President, 1789), Francis M'Evoy (thrice President, 1791, 1804, and 1807), Richard Dease, James Rivers, Cusack Rooney, James Kerin, Francis White, James O'Beire, Andrew Ellis, Leonard Trant, and Christopher Fleming, all Roman Catholics, occupied the presidential chair during the first three-quarters of a century of the existence of the College."

Annual Dinner of the Medical Society of London.

THE 126th Annual Dinner of this venerable society took place at the Whitehall Rooms on Wednesday last (March 8th), Mr. E. Owen, President, in the chair. In point of view of numbers it proved to be the record dinner of the society, no less than 168 persons joining in the alimentary fray. Among the guests were the Presidents of the Royal Colleges and of the principal sister societies. In proposing the toast of the evening the President gave a humorous sketch of difficulties with which the Society had to contend in its earlier days, and made some very pertinent remarks on the qualities expected of papers expected to be read before the Society. He deprecated non-contentious papers which could only excite admiration, urging that a paper should be bold in outline, here and there a little aggressive, with some apparently straying lines, so that when read it should excite a desire to discuss it in the minds of the listeners. He added that a paper should not betoo long or "gaseous," and when printed should not contain too many footnotes referring the reader to other writings which had not come from the author's pen. Nothing, he remarked, would be lost if the writer now and then feigned a transient disbelief in his own omniscience. An interesting feature was the presentation to Dr. Monckton Copeman, of the Fothergillian medal, the award whereof we recently announced. The musical arrangements, which were of exceptional excellence, were under the management of Dr. R. Maguire, to whom the Society was indebted for the pleasure of hearing Dr. Plimmer on the piano and Mr. Foster Ferguson in his admirable rendering of various ditties.

Mortality in Foreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Calcutta 38, Bombay 112, Madras 46, Paris 20, Brussels 20, Amsterdam 16. Rotterdam 16, The Hague 13, Copenhagen 25, Stockholm 24, Christiania 23, St. Petersburg 27, Moscow 26, Berlin 17, Hamburg 18, Breslau 29, Munich 22, [Vienna 23, Prague 30, Buda Pesth 31, Trieste 19, Rome 19, Turin 21, New York 18, Philadelphia 23.

GEORGE VINCE, the most notorious exponent of the doctrines of the "Peculiar People," has lost another of his children, the fourth out of nine, so that whatever the ethical importance of the treatment may amount to, it cannot be regarded as therapeutically successful. He was charged last week at the West Ham Police Court with having caused the death of his child by withholding medical assistance. As the medical evidence did not support the suggestion that death would have been averted by skilled advice, the prisoner was discharged. The case subsequently came before the Central Criminal Court on the coroner's inquisition, where he was also found not guilty, but the question was raised whether, as the prisoner was under recognizances in respect of a conviction for manslaughter in 1897, he ought not to be called up for sentence. The judge pointed out that it was for the Crown to decide whether the prisoner ought to be called upon to surrender to his recognizance, and in the meantime he was discharged. It is time this playing at justice ceased, and that a definite pronouncement was made for the future guidance of judges and

MEDICAL ETHICS IN INDIA.

THE following is the copy of a placerd posted up at all the public laces in Lucknow, which we reprint from the Indian Medjeal

places in Lucknow, which we reprint from the local physician and "Dr. M. S. Varis, M.B., C.M.Edin., consulting physician and surgeon. Consultation, all hours free, 9-11 a.m. Share Darvoza. "Notice.—Dr. Sayad Mahomed Varis, surgeon. Good news to thee, O heart; a Jesus-like man has come. Be it known to the seekers after bodily health and to those in the clutches of deadly diseases that the Aristotle of the times and Galen of the universe, Dr. Sayad Mahomed Varis, M.B., C.M., after learning the art of medicine and practising it in Great Britain, has come to this town (Lucknow). He studied for six or seven years in modern Athensevis., Edinburgh, which is the capital of Scotland. and he obtained the dinloma of a physician and surgeon; and there for three years ris., Edinburgh, which is the capital of Scotland. and he obtained the diploma of a physician and surgeon; and there for three years he established himself in practice and performed Christ-like miracles. It is our good fortune that he has established himself here. It is hoped that whosever will apply to him for treatment will fill his pocket with pearls of health. He lives close to Kaisar Bag, near Share Darvoza, opposite the telegraph office, in house No.

1. Patients can consult him all day."

1. Patients can consult him all day."

CROTDOM.—The extraordinary condition in the will you mention was doubtless due to a dread of being buried alive on the part of the testator. Upon the more general question as to the probability of such an occurrence, we must refer you to a little book entitled "Premature Burial, Fact or Fiction?" (Bailliere, Tindall and Cox), published in London last year. From an examination of published reports, the author concludes that no scientifically authentic instance is on record, and that the possibility of such an alarming event as live burial is exceedingly remote.

THE VALUE OF PULLET HOTTEP ANCES

THE VALUE OF PULPIT UTTERANCES.

MR. F. LAWRENCE writes us that the late Sir Douglas Galton was alive to the influence exercised by the pulpit in regard to sanitary matters, and thought that set sermons should be preached on such subjects as "Consumption, and How to Prevent It." But for the fatal termination of his illness he would have presided at the forthcoming annual meeting of the Church Sanitary Association at Westminster.

DR. A. DEPAGE (Brussels).—Our "Exchange List" is already too full, we regret we are unable to accede to the request on behalf of "The Société Belge de Chirurgie."

Ergo. It has been calculated that a cyclist weighing between eleven and twelve stone, riding a machine weighing 40 lbs., at an average rate of ten miles an hour, consumes 45 c.c. of oxygen per yard. This falls 6 per cent. when the rate is reduced to six miles an hour, and increases 10 per cent. if the speed is accelerated to fifteen miles an hour. At ten miles an hour the cyclist consumes yard. This falls 6 per cent. when the rate is reduced to six miles an hour, and increases 10 per cent. if the speed is accelerated to fifteen miles an hour. At ten miles an hour the cyclist consumes seventy-two litres of oxygen per hour, as compared with the pedestrian, who, at four miles an hour, does not consume more than sixty litres.

Palatable. Chroat Pastilles.

These Pastilles have now for many years been employed by the Faculty in the relief of Throat Affections. Their form enables them to be more easily sucked than the ordinary hard lozenge; while the Pate de Jujube from which they are manufactured is particularly palatable, soluble and demulcent in its action.

The following are examples only of the Pastilles in

- No. 9. Menthol, Cocaine, and Red Gum. Menthol et Cocainæ, aa. gr. 1-20; Gummi Rubri, gr. ii. Antiseptic, Sedative, and Astringent.
- 11. Chlorate of Potash. 1 grain in each. Better than the B.P. form.
- Compound Eucalyptus. (Red Gum, Chlorate of Potash, and Cubebs. A valuable astringent.
- Compound Rhatany and Cocaine. Ext. of Rhatany, gr. ii.; Cocaine Hydrochlor., gr. 1-10. A very efficacious astringent and anodyne.
- Gocaine, Chlorate of Potash, and Borax. Especially useful for the tickling of a slightly relaxed throat.
- 44. Menthol and Cocaine. 1-20th of a grain of each in a Pastille. The antiseptic and stimulating action of the Menthol, combined with an effective Anodyne.
- Menthol and Rhatany. 1-20th of a grain of Menthol in a Pastille. Stimulating, antiseptic, and mildly astringent.
- Tannin, Cayenne and Black Current Is far more palatable and efficacious than the ordinary lozenge.

In prescribing it is only necessary to add the letters A. & H., these being registered as a Trade Mark; thus—Tannin Pastilles A. & H.

A list of 54 varieties, and a sample box containing specimens of six kinds, supplied free to medical men on application.

TABLOID'-

HILST the therapeutic values of many of the animal substances, which have been made the subjects of physiological and clinical research, still remain undecided, there can be no doubt that certain of the 'Tabloid' Animal Substances have proved most useful in the treatment of disease.

'Tabloid' Thyroid Gland Substance

has been, from the first, most closely associated with successful Thyroid-Therapy, and reports conclusively demonstrating its value are repeatedly appearing in the British and Foreign Medical Journals.

'Tabloid' Supra-renal Gland Substance

has also been the subject of clinical investigation and favourable report. It causes contraction of the arteries, and consequently increases the blood pressure. Reprints of articles will be gladly forwarded to medical men on request. For Therapeutic Notes see Wellcome's Medical Diary, page 130.

*Tabloid Thyroid Gland Substance is supplied in two strengths, gr. 1-1/2 and gr. 5, in bottles of 100, at 10d. and 2s. per bottle.

'Tabloid' Supra-renal Gland Substance is supplied in bottles of 100, at 4s. 6d. per bottle.

The Harben Lectures.

THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS.

By Sir RICHARD THORNE THORNE, K.C.B., M.B., F.R.S., Medical Officer to the Local Government Board.

ABSTRACT OF LECTURE II.

I have had hesitation in adopting some of the more advanced views which have been put forward, both as to the amount of risk to which man is subjected through the consumption of the meat of tuberculous animals, and as to the measures of control which have in consequence become necessary, I know no grounds which would justify me in attempting to minimise either the risk which arises from the consumption of the milk of tuberculous cows, or the grave consequences to which the practice gives rise in this country. Indeed, I am profoundly convinced that the danger is great and widespread, and that it is absolutely necessary for those e. gaged in the pursuit of preventive medicine to take a prominent place in arousing the public to a proper appreciation of the fatal consequences to which it gives rise.

I have already pointed out that the form of tuberculosis most identified with the reception of the tuberculous infection into the digestive tract is that which in its fatal form is registered under the heading "Tabes Mesenterica." While the mortality from tabes mesenterica at ages between 15 and 45 years is only 44, it rises to one of 1,577 per million living under 5 years of age; and under 1 year of age it reaches no less than 4,046 per million births.

Then, too, if we contrast the reduction of 27.9 per cent. which has taken place during the last 45 years in all forms of tuberculosis, and that of 66 per cent. in phthisis with the corresponding one from tabes mesenterica, which only reaches 2.9 per cent., you will see that in considering the latter cause of death we are dealing with a totally different state of affairs.

If we limit ourselves to the first year of life, when milk is most largely used as a food, we find that the reductions in the rate of death from the various forms of tuberculosis, which reduction has been going on for about half a century, not only disappears, but is actually transformed into a large increase, reaching no less than 21.7 per cent.

From whatever point of view we regard this ominous increase in the rate of death from Tabes Mesenterica among infants, we are forced to the conclusion that it is largely related to the use as an article of food of the milk of the bovine animal.

We must not overlook the fact that there is some relationship between tabes mesenterica and diarrhoea, indeed, the rates of death from these two diseases commonly rise and fall together. Apart from errors of diagnosis I infer that the existence of an intestinal condition leading to diarrhoea, or the absence of any such condition, largely explains whether or not an infant, or even an adult, will be susceptible to, or experience immunity from, the infection of tuberculosis. It seems to me that a really healthy animal, whether man or one of the lower animals, is not easily susceptible to the effects of a pathogenic organism such as that which we are, considering, and to which he must so often be

exposed, whether the bacillus be conveyed acrially or by means of food; whereas, on the other hand, when that organism reaches a surface which exhibits an evanescent or more lasting departure from that normal state which we describe as healthy, the matter is different.

It now becomes necessary to consider more in detail what is the nature of the evidence to the effect that the milch cow is a danger to man, in the matter of tuberculosis, through the agency of her milk.

We know that the bovine race is peculiarly susceptible to tuberculosis, and that it is the female which, to a much greater extent than is the case in the human subject suffers most. The conditions favouring tuberculosis are also altogether exceptional in the case of the milch-cow. In the first place, there is the exhausting process involved in the production of milk, a process associated in the milch-cow with the constant loss of fat, albumen and salts contained in milk, and with a consequent tendency to emaciation. Then, too many cows are kept and fed under conditions which are altogether opposed to Nature, especially in towns where they are kept in cowsheds in which, for the purposes of warmth, they generally lie in couples in close contact with each other, with inadequate ventilation; and it is no uncommon thing to find that cows which, in their natural state, live and graze in the open air, never for one moment leave their sheds for the outer air during the whole period—often ranging from 8 to 12 months—in which they are used for milking. Their food, too, is especially selected with a view to the production of milk. In fact, they are artificially turned into milking machines. By my reference here to towns I by no means exclude country cowsheds in so far as conditions are favourable to tuberculosis are concerned. That is a point to which

In forming some estimate as to the number of milch-cows in England and Wales affected with tuberculosis, very varied evidence is available, but if I take it for the purposes of these lectures that 25 per cent. of our milch-cows are tuberculous, I feel confident that I greatly understate the case. There are in England and Wales about 2,100,000 milch-cows, and on this low estimate some 525,000 would be tuberculous.

All tuberculous cows are not, however, necessarily a source of danger through their milk. Indeed, in so far as immediate danger to the human subject is concerned, it is only the cow with tuberculosis of the udder that exhibits tubercle bacilli in the milk, as proved by an experiment carried out under the auspices of the Royal Commission of 1890, by Dr. Sidney Martin, on seven-teen cows believed to be tuberculous. Only fifteen turned out on slaughter to be so, and of these it was found post-mortem that five had some tuberculous affection of the udder. In the case of ten out of the fifteen tuberculous cows, eight had healthy udders, and two had an udder affection which was ultimately found not to be tuberculous. In no single samples of milk from these ten tuberculous cows with non-tuberculous udders could tubercle bacilli be found, and sixteen test animals, which were fed on, or inoculated with, their milk, remained perfectly free from tuberculous disease. Of the five cows which turned out to have tuberculous disease of the udder, three exhibited tubercle bacilli in their milk, and Fifteen test animals were fed with the two did not milk that contained tubercle bacilli, with the result that tuberculosis was produced in every one of them. Ihe milk of one or other of the two cows having tuberculous udder disease, without evidence of tubercle bacilli in the

milk, was used as food for twelve test animals, and four of these became tuberculous. On the other hand, similar experiments, including the inoculation of animals, made with the milk of the two cows having an udder affection, which was found to be non-tuberculous, failed to give tuberculosis to any of the test animals employed.

The deposit of small tubercular masses in a bulkvorgan such as the udder of a milch-cow is most difficult to detect, and it is by no means always possible to detect the existence of tubercle bacilli in milk which is potent to communicate tuberculosis. In fact, it is very important to remember that the failure to detect tubercle bacilli in a single sample of milk in no way implies that another sample taken at another time from the same cow will not contain them, for the spread of tubercle in the udder "goes on with alarming rapidity." This difficulty of detecting tuberculosis of the udder in its earlier stages, indeed constitutes one of the principal dangers to man as a consumer of cow's milk.

In determining what are the administrative measures of control which are necessary to meet this evil, the one which first presents itself to most minds is the exclusion of all tuberculous cows from dairies. The presence in a dairy of a tuberculous cow, as Drs. Martin and Woodhead have shown, is a decided source of danger to the public, especially having regard to what we have learnt respecting the rapid development of tuberculosis in the udder, and the degree of danger to milk-consumers incurred by the invasion of the udder in tuberculous cows.

What would be the effect of at once eliminating every tuberculous cow from our dairy-farms and cow-sheds? Even on the low estimate which I have already given you more than half a million cows would have to be at once withdrawn from the milk-supply of England and Wales, and yet the majority of these cows are probably supplying milk which is derived from healthy udders; and if we held the view that every cow which, in the hands of an expert working with material prepared according to an acknowledged standard, responded to the tuberculin test, then the proportion to be condemned as milk suppliers would be very much greater. Whatever, therefore, the ultimate end which we may rightly seek to attain, we must at least commence on lines that are practicable of application.

Foremost among the measures to be advocated is the adoption throughout the country of regulations as to cowsheds which will give our dairy cows a better chance han they now have of avoiding the infection of tuberculosis during the term in which they are confined in sheds and byres for the purposes of milk production.

At present both the law and practice are deficient in this matter. No department of Government is invested with the power of laying down regulations as to the construction, ventilation, or provision of air-space in cowsheds, the details of which they can enforce. All that the Government can do is to refuse sanction to the operation of any regulation which they "are satisfied on inquiry . . . is of too restrictive a character, or otherwise objectionable." The result is that the existing regulations differ widely in different districts in matters which we now know to be of vital importance.

which we now know to be of vital importance.

The Royal Commission of 1896, whilst recognising the immense difficulty—indeed, impossibility—of at once attaining all that is needed in this respect, endeavoured to meet the more pressing need in this matter by laying down certain rules as to the registration and construction of cowsheds, and they urged that power should be conferred upon the Local Government Board to require the adoption of those rules. Their recommendations as to this were as follows:—(a) That in future no cowshed, byre, or shippon, other than those already registered shall be permitted or registered in urban districts within 100 feet of any dwelling-house; and that the discontinuance of any one already existing shall be ordered on the certificate, either of the medical officer of health that it is injurious to the health of human beings residing near ir, or of the veterinary inspector that it is not a place wherein cows ought to be kept for the purpose of milk supply, and that it is incapable of being made so. (b) That the conditions of the attached cowsheds that shall warrant the registering of a dairy in a populous place, whether technically urban or rural, in the future shall include

the following:—(1) An impervious floor. (2) A sufficient water supply for flushing. (3) Proper drainage. (4) A depot for the manure at a sufficient distance from the byres. (5) A minimum cubic contents as regards such districts of from 600 to 800 feet for each adult beast, varying according to the average weight of the animals. (6) A minimum floor-space of 50 feet to each adult beast. (7) Sufficient light and ventilation.

While we have prescribed a minimum cubic contents and floor space, without mentioning definite dimensions affecting ventilation and lighting, we are distinctly of opinion that these are by far the most important, and that requirements as to cubic and floor space are mainly of value as tending to facilitate adequate movement of air. The same conditions as those recommended for populous places should apply to cowsheds in sparsely populated places, except in so far as cubic contents per cow are concerned In hospital construction the first point to be aimed at in the matter of air-space is to secure adequate movement of fresh air at the level above the floor at which the patient is breathing, and hence that the provision of adequate floor-space, and still more of wallspace per bed, outweigh in importance the mere provision of cubic space. In the case of milch-cows the need for maintaining bodily warmth is held to be one that cannot be ignored, and hence it is that so small a minimum as 50 square feet is all that it was deemed expedient to require at the present time. But it is a step in advance to maintain that a minimum amount of floor-space must go hand in hand with a requirement as to cubic capacity; and to insist that both these shall be controlled by the requirement that the ventilation and the lighting of cowsheds shall be adequate.

There is a general impression that cowsheds in rural districts need less control in this respect than those in urban districts, but I can only say that, according to my limited experience, by far the worst constructed, worst ventilated, and the dirtiest cowsheds are to be found in villages, hamlets and rural areas. In small farms on hillsides and exposed places, where movement of air is said to abound, I have often found that a most inadequate cubic capacity has coincided with the blocking up of every opening and cranny that could afford reasonable means of ventilation.

Whilst I am certainly no advocate for the retention of cowsheds in towns and cities, yet I am bound to say that, with the present neglect of rural cowsheds, the city byres often take precedence of the country ones in the matter of tuberculosis. Thus, of 144 samples of milk taken from cowsheds in the city of Liverpool, 4, or 28 per cent., exhibited the tubercle bacillus; whereas of 24 samples taken at railway stations of milk arriving from "the country," the tubercle bacillus was found in 7, or "the country," the tubercle bachius was round and 29 1 per cent Later investigations in Liverpool showed gave 12, or 52 per cent. as infected with the tubercle bacillus, whereas in 67 samples derived from country cowsheds, 9, or 134 per cent, were found to be so infected. In Manchester similar inquiries have for some time past been carried out, and it has been found that out of 93 samples of milk taken at the railway stations on their arival from the country, 17, or over 18 per cent., contained the tubercle bacillus. Comparison between this country milk and that of cows in the city shippons was on this occasion not practicable, because earlier inspections had led to the removal from these city shippons of a number of cows suffering from suspicious udder disease, including five the milk from which contained tubercle bacili.

Facts such as those to which I have adverted, taken together with the prolonged detention of milch-cows in sheds point strongly to the need for more stringent and uniform control of these constructions. This will, I trust, before long be effected. I only wish I could also anticipate the speedy adoption of a regulation that would prevent cows being placed, as they now almost invariably are, with their nose and nostrils to the wall. If the object is the most effectual manner to deprive them of all chance of breathing fresh and moving air, nothing could better have achieved that end than the now prevailing system; and when we call to mind the fact that tuberculosis in the cow is, in the main, a matter of direct infec-

tion through the respiratory apparatus, this point becomes all the more important. To enact a requirement involving the abandonment of this practice would, of course, mean the provision of additional air-space; and this would under some climatic conditions involve measures of artificial warming to secure the temperature deemed necessary for milk production. In other words, it would mean increase of cost in construction, if not for the purposes of maintenance.

As to this, however, it may be interesting to put on record a piece of personal experience. On a somewhat recent visit to a large, well-managed dairy-farm on the outskirts of London, I observed that the cows were stalled down the centre of a shed measuring 17 feet 6 inches in width, a passage 4 feet 6 inches wide being provided both in front of and behind the cows. On inquiring, at a later date, how far this excellent arrangement necessitated artificial warming in the winter months, I was informed in writing by one of the owners of the dairy-farm that, although steps were taken during the colder weather to avoid actual draught, no artificial warming was ever resorted to. The "winter feed" for the cows, it was added, was found "sufficient" to enable them "to withstand any ordinary change of temperature." The writer, referring of course to an experience based on the climate of the metropolis, added: "I do not think a properly ventilated shed requires any artificial heating."

Proper regulation of cowsheds would bring about other advantages in our milk supply than those which are concerned with the prevention of tuberculosis. To name one of these only. I would refer to the necessity of forbidding the storage of cows' dung within a specified distance of the sheds. At present the air of sheds containing large numbers of cows is laden with the smell of decomposing dung piled up in proximity to them, and it must necessarily be highly charged with those bacillisuch as the bacillus coli—which find in the large intestine their principal habitation. But enough has been said to show that proper control in the construction and management of cowsheds and their surroundings is an administrative measure that is urgently called for; and I may add that uniform efficiency in this respect can only be attained as the result of further legislation.

Another point has to do with the need of systematic inspection of dairies and sheds, and of all cows the milk of which is placed on sale. This should be carried out by the officers of the sanitary authority of the locality in which the premises are situated. But since the milk used in one district is now so often derived from one or more outlying or even distant districts, power should be conferred by statute for the inspection of cows, wherever they may be situated, by the officers of the authorities within whose districts milk from the premises in question is supplied; and this power should everywhere be supplemented by the further one to suspend or prchibit the sale within the district of an authority of milk from any dairy, whether obtained within or without the district, whenever this is deemed necessary either by the medical officer of health or veterinary official by reason of the health of the cows.

Just as Scotland is ahead of England in the matter of public slaughter-houses, so also has she set us an example in this matter of the control of milk from tuberculous cows, wherever they may be situated. Sections 24-27 of the Glasgow Police (Amendment) Act, 1890, deserve consideration in England in this respect. And, further, there should, to use the terms of the Royal Commission of 1896, be power to prohibit the sale of milk from any cow certified by a veterinary surgeon to be suffering either from such disease of the udder as in his opinion renders the animal unfit for the supply of milk, or from any cow exhibiting clinical symptons of tuberculosis. And lastly, udder disease in the cow should be made a notifiable disease, and a penalty should attach to the sale of milk from any cow so suffering, unless the owner of the animal is in possession of a veterinary certificate to the effect that such disease is not tuberculous.

The possession of these powers as to suspending or of prohibiting the sale of milk from certain cows will, in many instances, involve the seizure of the animals in question by the local sanitary authority, acting on

veterinary advice; and here again, as in the case of the seizure of tuberculous carcases, we are met with the claim for compensation. But the circumstances are quite different. I have given my reasons for objecting to grant compensation for an article of food, like meat, which is placed on sale for the sole profit of its owner when it is seized because it is unfit for human consumption. But in the case of a milch-cow believed, or found on inspection, to be tuberculous, the animal has not been placed on sale. Apart from her milk, which is "seized" by reason of its sale being prohibited, the animal may be of value for, and quite fit for, the purposes of meat supply; hence confiscation of the cow herself would be wrong.

If, therefore, in the exercise of a power conferred by statute the sanitary authority should seize such a cow in the interests of the public, the seizure should be accompanied by compulsory slaughter. And if, on slaughter, the animal should turn out not to be tuberculous, then her full value as a milch-cow should be given to the owner out of the local rates; whereas if, on the other hand, the animal be found to have been tuberculous, only the value which the carcass may possess as a food supply or otherwise should be paid in compensation. The principles here laid down are, I believe, just and equitable. And it is worthy of note that whereas our national death returns from tuberculosis call for no departure from these principles in the case of our meat supply, those same returns point strongly to the need of their application in the matter of our milk supply.

Measures such as I have indicated would go far to control tuberculesis through the agency of milk; but it would be manifestly unfair, as well as wrong to the community, to apply them to the dairy-farms and cowsheds of this country, and at the same time to admit milk and milk products from abroad without submitting these to restrictions resembling, as nearly as practicable, those applied at home. Holding this in view, the Royal Commission, of which I was a member, made a recommendation to that effect, and they added that any costs thus incurred should be borne by the importers.

There remains the danger of the direct infection of tuberculosis from cow to cow—a danger which is the greater by reason of the fact that, to quote the words of the report of the Royal Commission of 1896, "the insanitary conditions under which dairy stock are often kept constitute highly favourable circumstances for the encouragement of tuberculous disease, and for its dissemination among sound animals." The experience derived from Denmark as to the action taken on the basis of the results of the tuberculin test, goes to show how much may be done to avoid this danger. Dairy cows to the number of 144,800 were submitted to the tuberculin test, with the result that in 45,899, or 31.7 per cent., tuberculosis in some stage or other was detected. The detection of unsound animals is followed by their immediate isolation from the healthy ones by the simple and inexpensive process of placing one set on one side of a wooden partition erected across the byre, whilst the other set are stalled on the other side. Each spring and autumn the sound set of cows are re-tested, and any that respond to the test are placed on the unsound side of the partition, the process being repeated so long as any react to the tuberculin.

In one typical form, at Thurebylille, this process had been carried on for five years. When the test was first applied, in 1892, it was found that 131 out of 208, or nearly two-thirds of the animals, were tuberculous, whereas in 1897 the matter was reversed; for out of 204 animals only 55, or one-fourth, reacted, the bulk of the animals being sound, and this notwithstanding the fact that the disease must constantly have been introduced afresh by means of newly purchased animals. Such action, if combined, in England, with proper administrative control of cowsheds, would probably be even more efficacious than in Denmark in securing the elimination of tuberculosis from our dairy stock. But the testing, to be trustwortby, must be applied under the supervision of experts, and the tuberculin must be of a guaranteed standard potency. How far control of tuberculosis in this direction should be administered under the direction of the State is. I believe a matter on which there is

some difference of opinion. The Royal Commission was, however, unanimous in making recommendations in this sense; and I am bound to say that I find it difficult to understand how the desired end of protecting the public health in this way can be properly attained, except as the result of some such action by the State as that which is adopted for the control of small-pox, and in which both the vaccinator and the necessary lymph can be obtained

at the public cost.

Thus far the measures of control which I have suggested have had concern with the cow, and the means of housing her; but, knowing as we do that the dried sputa from phthisical persons are easily mingled with the air, that the tuberculous infection of the cow takes place mainly through the medium of the air, and that aerial infection of milk easily takes place, it should be an invariable rule that no individual suffering from tuberculous consumption should be employed in connection with milch-cows, with dairy processes, or in the sale of milk, and such inspection and control as I have already advised should be accompanied by periodic examination of dairy employés, and certification as to their freedom both from tuberculous and other infections. Regulations can already be made under the Dairies, Cowsheds, and Milkshops Order, rendering it unlawful "to allow any person suffering from a dangerous infectious disorder

. to milk cows or to handle vessels used for containing milk for sale, or in any way to take part or assist in the conduct of the trade or business of the cowkeeper or dairyman, purveyor of milk or occupier of a milk-store or milk-shop, so far as regards the production, distribu-tion, or storage of milk. . . " But when this regu-lation was drawn up in 1885, the term "dangerous infectious disorder" was not regarded as including tuberculosis, and further restrictions, based on the assumption that an acute infectious disorder, such as scarlet-fever, was in question, and controlling persons who had even "been in contact" with a person so suffering, may raise some difficulty in applying this to a disease lasting at times for many years, besides which no provision is made for ascertaining whether a person is so suffering. This point raises the question of the notification of tuberculous disease notably phthisis, in man, a question to which I shall refer in my next lecture Then again, the adoption of such a regulation cannot be enforced, and it seems clear that to effect this, as well as other necessary reforms in relation to our milk-supply. fresh legislation will be required.

It is a somewhat curious fact that the inhabitants of the United Kingdom stand a'most alone among civilised nations in the habitual use of uncooked milk as a food. This is the more to be regretted because, by reason of this practice, human life, especially that of infancy and childhood, is being sacrificed on a scale which, to use the mildest term, is altogether deplorable. That this should be so is also altogether unreasonable in the face of the certain knowledge possessed, and which is set forth in the report of the Royal Commission of 1890 in the following words: "The most deadly tuber-culous material can be rendered absolutely innocuous, in so far as any spreading of infective disease is concerned, by the action of a temperature at which water boils." And again: "It is sufficient to state that boiling, for an instant even, renders the tubercle bacillus absolutely innocuous.

Even the taste which attaches to boiled milk, and to which infants become at once habituated, may be largely avoided if the milk boiled after the morning delivery be stored in the cool for use in the afternoon, and if the afternoon milk be similarly set aside until morning.

But some maintain that cooked milk is less nutritious than raw milk. There may be an element of truth in this. Milk is a fluid having a biological character; it is a living fluid, and this character is destroyed by boiling or sterilisation. From the purely scientific point of view it is most desirable to bear this in mind, but in its practical aspect it is well to remember that the slight diminution in nutritive value which cooking brings about in milk cannot be named side by side with the immense gain in freedom from the risk of infectious disease and death which is thus insured.

One word more. Milk, as it comes from the normal

milk gland, is a sterile fluid, and it would be well for future generations if mothers could be brought to realise that "there is no sterilising apparatus that can give results comparable with those provided by Nature in the healthy female breast." Happily I can add that tuberculosis in the human milk glands is a disease so rare that it hardly needs consideration in connection with the feeding of infants. At the child-bearing age it is all but unknown.

Dr. Sidney Martin informs me that out of some 9,000 patients, mostly suffering from tuberculosis-namely, phthisis-which have come under his own care, he has never met with tuberculosis in the mammary gland. He adds that in only one instance has such an occurrence been brought under his notice, in the patient of another physician, and even that case he regarded as more than doubtful. The need for educating the public of this country as to the risks involved in the use of raw cow's milk, and as to the simple methods by which these risks can be effectually avoided, is a pressing one, and it can only be met by enlisting the active services of my own profession. Our influence in such a matter is necessarily considerable; our responsibility is a correspondingly heavy one.

THE MODERN DOCTRINE OF BACTERIOLOGY, OR THE GERM THEORY OF DISEASE, WITH SPECIAL REFERENCE TO GYNÆCOLOGY. (a)

By GEO. GRANVILLE BANTOCK. M.D., F.B.C.S.E., Consulting Surgeon to the Samaritan Free Hospital for Women.

AFTER a few preliminary remarks Dr. Bantock said, I am quite aware that my views will probably be regarded, by a majority of those present, as very heterodox, but that does not deter me from giving expression to them and boldly courting publicity, notwithstanding the belief that they are only too far in advance of those held by my contemporaries for immediate acceptance. I am very anxious to call attention again to this subject, for I am driven to the conclusion that few of you took any interest in a discussion which occupied the correspondence columns of THE MEDICAL PRESS AND CIRCULAR, & little over two years ago, on the modern doctrine of bacteriology, and which arose incidentally out of the question, "What is Listerism?" It is a fact worthy of note that no follower of Lister, no modern bacteriologist, dared to enter into that discussion, or, if there were such an one, had the courage to disclose his name.

Before proceeding further it will be well to define what I understand to be the modern doctrine of bacteriology. It is this, viz., that in the majority of, or as some extremists would seem to hold, all acute diseases, the condition is due to the influence of a specific so-called pathogenic micro-organism. Hence we hear of the typhoid bacillus, the diphtheria bacillus, and so on. This is the doctrine that I proceed to combat by pro-pounding the very opposite doctrine, that the presence of these various micro-organisms is the result and not the cause of disease—in other words, that the bacilli are found in association with the disease because of the disease, or that the disease furnishes the conditions necessary for the presence of the special micro-organism.

You may have overlooked or forgotten a very important fact told us by Dr. Newman. He told us that in the examination of the vaginal discharge of a healthy woman, obtained for him by one of his colleagues, he found a great variety of organisms, and among them the staphylococcus pyogenes and streptococcus pyogenes. In the abstract published in the *Journal* of this Society, he tells us that "more than thirty different species of micro-organism have been isolated from the female genital tract, or from discharges." confirmed by numerous observers. Dr. Whittridge Williams also tells us that in the vaginal discharge of pregnant women "pyogenic bacteria were found

in the vulval secretion in nineteen cases (76 per cent,)" and within the vulva in 48 per cent. Among those enumerated by Dobbin we find, in addition to the two just mentioned, the bacillus coli communis, the bacillus of tetanus, Klebs-Læffler bacillus of diphtheria. and the bacillus typhosus. Dr. Newman adds that "the most frequently present is the staphylococous pyogenes aureus, which is the commonest of the group of suppurative bacteria." Here we have the doctrine plainly indicated—and I need not trouble you with any more examples -viz., that the staphylococcus pyogenes and the streptococcus pyogenes are, as the name implies, the cause of suppuration. A strange part of this doctrine is this, viz., that the vagina is said to be the habitat of a bacillus-Döderleins-which "is inimical to the or a bachina-boderiens—which is limited to the presence or prolonged existence of so-called pathogenic bacilli —like the good fairy in the pantomime defeating the machinations of the wicked fairy.

A great deal of light has been thrown on this subject within the last three or four years. I presume you are all acquainted with the fact that Dr. Geo. Stoker has been treating chronic ulcerative conditions, with the most gratifying results, by means of oxygen gas. Now, it happened that in the early days of his work he had under his care a woman who had been bedridden for many years with a large ulcer involv-ing the whole of the instep of each foot. These ulcers were almost precisely alike in form and extent, and it was suggested to him that one should be treated with corrosive sublimate and the other with oxygen gas, for the purpose of comparison. In a very short time it was easy to perceive a difference between these two ulcers; for while in the former the surface was certainly cleaner than at the beginning of the experiment, yet it presented an ashey-grey appearance, and exhibited very little sign of healing, the latter presented a healthy granulating surface with a good margin already healed over. A gentleman from the Clinical Research Associa-tion now appeared upon the scene, and took some of the discharge from each with a view of obtaining a culture. This was the astounding result, viz., that the first wasto use the current language -sterile, while the latter (oxygen case) gave a copious crop of bacteria, and what, think you, was the organism which stood out most prominently? It was this very staphylococcus pyogenes, which, with the streptococcus pyogenes, we are told, is the prime cause of suppuration. From that time Dr. Stoker took up the study of bacteriology as applied to this part of the subject, and at the annual meeting of the British Medical Association in this city, in 1895, he gave an account of his work. As reported in the Journal of the Association, one of the important points to which he called attention was thus expressed: "(3) The bacteriological aspect of one case was surprising and rather upset one's preconceived ideas." Dr. Stoker returned to the subject at the next meeting—at Carlisle—but I fear his communications have had few readers. Having, from the time of the incident above referred to, taken to the study of bacteriology as applied to this subject, Dr. Stoker found that whenever the healing process appeared to falter, either under a diminished or an insufficient supply of oxygen, this was an indication for an increase, or for inoculation from a more healthy sore; and his observations led him to the conclusion that in proportion as the staphylococci were numerous and well developed so the healing process progressed. What, then, is the natural, common-sense conclusion from this? It is this, that the staphylococcus pyogenes, which, as its name implies, has hitherto been regarded as the prime cause of suppuration, and therefore of the destructive process, must henceforth be regarded as, to say the least, doing no harm, and, it may be, as playing a beneficent role in the economy of nature, and, in non-technical language, may be looked upon as playing the part of a scavenger.

It will probably be regarded as the rankest heresy when

I express any doubt as to, much more a decided opinion against, the influence of the gonococcus as the prime agent in the production of gonorrhea. As in the case of diphtheria, numerous observations are on record of cases of gonorrhosa without gonococci, and vice versa. Dr. Newman tells us that "it is now well known that the gonococci diminish in number as the disease becomes chronic." That is to say, that as the disease becomes less acute the amount of the poison—the food on which they live-diminishes in quantity, and the gonococci are less numerous. It is marvellous, if it were not ridiculous, to what lengths some will go in their endeavour to bolster up a favourite theory. As an example take the following. To account for the recurrence of this disease in a subject who had presented no sign of it for several years, and in support of the doctrine of latent gonorrhosa, it has been suggested that an old decrepit gonococcus has been roused into activity by sexual excess, and thus there has been brought about a recurrence of the disease—as probable as the case of the fatted calf that had been in the family for many years.

I am also aware that I am a heretic as to the importance of gonorrhæa in the production of pelvic inflammations, but I claim Dr. Newman as at least a tacit supporter; for has he not these words without adverse comment? "It is said that gonococci are present in one of every four cases of pyosalpinx." Surely that is a very small proportion on which to establish the proposition that gonorrhosa is answerable for the majority of cases of pyosalpinx. On the contrary, it supports my contention that it is only a factor in the minority of cases.

As an example of the difficulty into which a rigid appli-

cation of this doctrine leads one—I refer you to Dr. Robinson's paper on "Vulvitis in Children."

You are doubtless aware that it is generally admitted by bacteriologists that the skin of the hand, and indeed all parts of the body, though not all equally, teem with a bacillus to which the name staphylococcus albus has been given; that this bacillus is supposed to be possessed of pathogenic properties, and that elaborate processes have been invented for the purpose of destroying it. I refer especially to that described by Howard Kelly as perhaps the most elaborate. You are probably also aware that no process hitherto invented has yet succeeded in getting rid of these micro-organisms, so deeply are they situated. Hence the skin itself-including the hands of the operator and that part of the patient involved in the operation—is said to be in a sentic condition requiring more or less elaborate treatment. I might refer to innumerable observations by different workers in this field; but one will be sufficient for my purpose, and I take a paper published by Mr. Lockwood (British Medical Journal, September 17, 1898), entitled, "Further Report upon Aseptic and Septic Surgical Cases." In that report Mr. Lockwood tells us that, with regard to his hands, "the skin was aseptic thirty-five and septic six. . . . Once it was some variety of staphylococcus albus." Just before he "had operated upon a case of ruptured perineum in which there was a vaginal discharge." One would like to know what became of that case, in which we may assume there must have been an abundance of micro-organisms-such as the staphylococcus and streptococcus (pyogenes), which so abound at the vulvar opening whenever there is any discharge.

With regard to the patient's skin, he says, "The skin of the scrotum is extremely difficult to disinfect, and with the exception of the scalp, has a higher proportion of sepsis than any other." "Nevertheless, the scrotal wounds have done exceedingly well." "Since 1894 I have done twenty-five, and none of them suppurated. Thus the sepsis of the scrotal skin has evidently a very small influence upon the repair of scrotal wounds." What an extraordinary comment!

Now let us see what is the meaning of this word sepsis. It is as follows, as given in Funk's "Standard Dictionary of the English Language:" "(1) Poisonous putrefaction causing noxious effects on the vital properties or texture of organs. (2) Infection from a putrescent virus containing microscopic organisms, as sepsis from putrid matter or bacteria in a festering wound." The equivalent, then, of this, in plain English, is "poisonous" or "poisoned." I give Mr. Lockwood his choice of these definitions. Does he contend that the skin of a healthy subject, in any part of the body, is in a condition which answers to either of these definitions? But this is the natural condition of the skin. How absurd, then, does it not all seem! How much more rational and logical the view that these organisms are there for a specific and beneficent purpose! How is it that he has not perceived the force of his own conclusion in the words I have already emphasised.

On this subject a very interesting abstract, furnished by its Berlin correspondent, has been published in the MEDICAL PRESS AND CIRCULAR for November 23rd, 1898, under the title, "The Bacteriological Condition of Wounds under Antiseptic Treatment." Dr. Kopinski, having concluded a series of bacteriological investiga-tions on animals has arrived at certain definite conclusions, as follows:-

"The performance of operations, whether aseptically or anti-septically, assures no absolute sterility of wounds, and it is difficult to say which of the two methods, in this respect, is the better. Antiseptic means in operations on healthy tissues must be given up, as they do not approach an attainable degree of sterility so nearly as asepticism does. In healing by first intention, both approphytes and pathogenic micro-organisms are retained in the wound. In a wound healed by first intention both Staphylococcus aureus and albus were met with cocci frequently found their way into wounds, and, as a matter of fact, the skin showed itself to be a chief hindrance to sterility, as its microbes were deep-seated, and on this account were only removed with difficulty.

Hence it follows that sepsis, according to Mr. Lockwood's phraseology, or the presence of the Staphylococcus pyogenes arreus itself has evidently a very small or no influence upon the repair of wounds and surgery

has not ceased to be a possible art.

Probably it will not be news to you that I adopt none of the elaborate precautions of Dr. Howard Kelly, or the less complicated method described by Mr. Lockwood, beyond the simple washing of my hands previous to opera-tion, and of my instruments after. While I am content with making my hands as clean as an ordinary washing with soap-and-water will make them, thus removing Lister's "grosser forms of septic mischief," I fear Mr. Lockwood will think they must be horribly septic. Yet with this simple precaution I stitch up a recent rupture of the perineum, it may be some hours after its occurrence, merely taking the additional precaution of wiping off any lochial discharge from the raw surface with a sponge and then placing another in the vagina to keep back the discharge, and I have never had a failure. I make a fresh wound in a ruptured perineum, stitch it up and obtain union by first intention. If I happen to pull a stitch too tight, the tissues become strangulated, their vitality is lowered, and I may get some suppuration in the track of the suture, but so uniform have been my final results that I have never had a case break down. In a case in which the whole perineum and vulva were in a state of extreme irritation from the relaxed or irritable state of the bowels—due to the exposure of the mucous membrane of the rectum—and without any precaution beyond wiping the surface with a warm, wet sponge, I secured union by first intention, the diarrhoea ceasing from the moment of the completion of the operation. I dissect out vulvo-vaginal glands, obliterating the cavity in stages; I remove growths from the vulva, stitching up the wounds, and have never failed to obtain union by first intention. I sew up a bilacerated cervix and have yet to record a failure. I have excised a considerable number of breasts, and the one in which I have failed to obtain union by first intention was the first and only one I did under the carbolic spray. So uniformly favourable have been my results since that case that I have come to regard it as one of the most simple operations in surgery. Moreover, in one case in which it was impossible to bring the flaps together I left the wound freely exposed to the air, with the result that the healing process went on as well as, if not better than, under the most approved dressing, and, aided by two or three skin grafts, the wound healed over completely. This in a public hospital. I have removed sebaceous cysts from the scalp—which, according to Mr. Lockwood, most abounds in septic micro-organisms—without any trouble resulting. I have, either by accident or of set purpose, opened the small intestine, the rectum, urinary bladden and varieties in the state of the small intestine. bladder an i vagina in abdominal operation, in which the bacillus coli must, for a short time at least, have had free access to the peritoneal surface, without any harm. And if I obtain these good results by the

adoption of simple cleanliness—in the common, every-day acceptation of the term - and such arrangements as any well-ordered private house can affordnecessity for all those elaborate precautions which we hear of in the case of private and even public "installations" as they are called—for instance, "the floor of encaustic tiles, well-laid parquet thoroughly saturated with wax and highly polished, cement or highly-glazed linoleum," all angles of walls rounded off, the walls and even the shelves and doors covered with a hard, smooth cement, coated with some kind of enamel, such as Flico-teaux's "lacquered paint"; the sterilising of instruments and dressings, the spraying of the room for an hour or two before the time of operation, and so forth-precautions and preparations so elequently satirised by Mr.
Treves in "The Ritual of an Abdominal Operation?"
For instance, "These words 'strict antiseptic precautions' have been with many a kind of mystic writing on the wall. . . Those who come after us will read with interest of the operating theatre built like a diving tank, of the glass table for the patient," so different from his own which is not even "bacteriologically clean," "of the exquisite ceremonial of washing on the part of the operator, of the rites attending the ostentatious cleansing of the patient, of the surgeon in his robes of white mackintosh and his indiarubber fishing boots, and of the onlookers beyond the pale who are excluded, with infinite solicitude, from the sacred circle as septic outlaws."...
"This exhibition may be scientific, but it is no part of surgery. It is more allied to a fervent, idolatrous ritual brought down to the level of a popular performance."

But does the observance of this elaborate "ritual" yield any better results than the observance of simple cleanliness? I aver that it does not. The operations I have named may be regarded as test operations; for are we not told that the orifices of the mucous passages especially swarm with bacteria—the bacillus coli, for instance—and that vaginal discharges contain the staphylococcus and streptococcus pyogenes in abundance? And how are you going to carry out these elaborate precautions in a private house—the home of the patient — where cases do so well? I often wonder how the men who hold these views ever dare to operate on a cleft palate or hare lip, seeing that the mouth contains a greater variety of bacteria than any other part of the body, from the most innocuous to the most virulent, so-called.

There was a time when the bacillus coli was regarded as a most virulent microbe—a veritable wild beast—and when, if the intestine, by an unlucky chance, got wounded in the course of an abdominal operation and the patient died, the death was attributed to the baneful action of this organism. The late Professor Kanthack showed that this organism is a natural inhabitant of the digestive tract, and that its absence or reduction in number must be regarded as a departure from perfect health.

Thus it has come about, from the observations of Dr. Stoker, that the staphylococcus pyogenes can no longer be regarded as the prime cause of suppuration, but rather as a beneficent organism; from the investigations of the late Professor Kanthack, that the bacillus coli must be relegated to the same category; and from the observa-tions of a host of investigators, that the staphylococcus pyogenes-and even the streptococcus-is found in conditions consistent with, at least, apparent health.

But it has been affirmed that Nature has provided a

wonderful mode of escape from the ravages of these noxious organisms, and has provided us with an arrangement for their destruction. I refer to the doctrine of phagocytosis of Metchnikoff, to which Sir Joseph Lister (as he then was) pinned his faith less than three years ago. I never could accept this comforting doctrine. It was far too circumstantial for my ideas of what was possible in the way of microscopical demonstration, much too clear to be regarded as anything but the product of a lively imagination, much too like seeing through a milestone for my acceptance. I take credit to myself for my unbelief, for the theory is now almost universally discredited. But I do not ask you to accept my estimate of it. Read what Professor Buchner said of this absurd doctrine at the Munich Medical Society last year. as published in the MEDICAL PRESS AND CIRCULAR of April, 1898, in which he came to this conclusion: "Metchnikoff s explanation is, therefore, a fable."

It is perhaps necessary to remind the younger generation, who may not have studied the question from the beginning, that the antiseptic system was founded on the hypothesis that germs floating in the atmosphere fell into wounds, there developed into their respective bacteria and produced all the evil effects that sometimes followed surgical operations. I cannot but think that the address of the inventor of the system, delivered before the International Medical Congress at Berlin, has not been read so extensively as it deserved to be, and therefore it is that I feel obliged to direct your attention to it, at the same time commending it to you for perusal. Want of time forbids me to quote largely, as I could have wished, and I must be content with directing your attention to some only of the most salient points. He says: that "by means of the phagocyte theory of Metch-nikoff"—which I have already shown you is now universally discredited—"we can account for what would otherwise have seemed to me incomprehensible—the use, without evil consequences, of silk ligatures, which have not been subjected to any antiseptic preparation. . . Dr. Bantock, whose remarkable series of successful ovariotomies may seem to justify his practice, does not, I believe, prepare his ligatures antiseptically. The success achieved by Bantock and Tait, without, it is said, the use of antiseptic means, proves a stumbling-block to some minds." No doubt, so long as they hold to the germ theory. "I can see that while the measures" (comprehended under the term cleanliness) "to which I have referred are, so far as they go, highly valuable, it must be in itself a very desirable thing to avoid the direct application to the peritoneum of strong and irritating antiseptic solutions." This latter is in itself a strong justification of my abandonment of carbolic acid. He continues, "As regards the spray, I feel ashamed that I should have ever recommended it for the purpose of destroying the microbes in the air. If we watch the formation of the spray and observe how its narrow initial cone expands as it advances with fresh portions of air continually drawn into its vortex, we see that many of the microbes in it, having only just come under its influence, cannot possibly have been deprived of their vitality. Yet there was a time when I assumed that such was the case, and trusting the spray I assumed that such was the case, and trusting the spray implicitly, as an atmosphere free from living organisms, emitted various precautions which I had before supposed to be essential." He then describes how, in a case of operation for empyema, "the air passed freely in and out of the pleural cavity" in a cloud of spray, and he arrives at the conclusion that "it is physically impossible that the microbes in such air can have been, in any way whatever, affected by their momentary presence in the air." "If then," he continues, "no harm resulted from the admission day after day of abundant atmospheric organisms to mingle unaltered with the serum in the pleural cavity, it seems to follow logically that the floating particles of the air may be disregarded in our surgical work, and if so we may dispense with anti-septic washing and irrigation, provided always that we can trust ourselves and our assistants to avoid the introduction into the wound of septic defilement from other than atmospheric sources." What these sources are we learn from his address at Liverpool, on September 16th, 1896, six years later, "Hence I was led to conclude that it was the grosser forms of septic mischief, rather than microbes in the attenuated condition in which they existed in the atmosphere, that we had to dread in surgical practice.

All these things, which are facts, not opinions, capable of demonstration and proof, go to show that the modern dootrine of bacteriology is a gigantic mistake; that we are already at the parting of the ways, and that it is safe to predict that, ere long, it will come to be recognised that these various bacilli play a beneficent rôle in the economy of nature. I am very far from having exhausted my subject; for, while I have only touched with a light hand upon some portions of it, I have omitted others

altogether.

[On account of the great length of Dr. Bantock's

address, we have been compelled to hold over those portions of it relating to typhoid epidemics, tuber-culosis, and the plague.—Ep.]

PERITONITIS

AS A CAUSE OF INCREASED

PERISTALSIS IN THE RECTUM AND OTHER PARTS OF THE BOWEL. (a)

By C. WALKER CATHCART, F.R.C.S., &c., Assistant Surgeon, Edinburgh Royal Infirmary.

IT is generally stated that peritonitis always causes paralysis of peristalsis. I was first led to doubt this on meeting with the following cases:—(1) A woman had begun to menstruate a fortnight before being seen; the period suddenly stopped, and then, after ten days' interval, returned. The patient then suffered from an attack of tonsillitis, and during this illness she was suddenly seized with severe pain in the lower part of the abdomen. When first observed, her chief complaint was constant tenesmus, so great as to compel her to lie straining over a bed-pan. The temperature was normal, the pulse fairly good, and the abdo-minal wall, though resistant, moved with respiration. A diagnosis of the presence of an impacted mass of fæces in the sigmoid flexure, causing the desire to empty the bowel, was made. The patient died suddenly within three hours of the onset of the abdominal pain, and on post-mortem examination a purulent pelvic peritonitis was found. The pus contained streptococci, and the infection appeared to have originated from the tonsillitis. (2) A woman, five months pregnent of her first child cot a chill cot a chill five months pregnant of her first child, got a chill ten days before being seen. This was followed by pelvic pain and dysuria, the latter requiring the use of the catheter. Suddenly, after a purge had acted, the patient felt a lump in the perineum, and began to suffer from great bearing down and tenesmus. When I saw her, she was suffering from recurrent attacks of pain, resembling those of impending abortion. There were, however, no other signs of this, and, on examining the perineum a resonant swelling was found. It was thought that this was probably a hernia, and that it was causing the straining efforts. An attempt to reduce it under chloroform failed, and, as the symptoms were not very urgent, operation was post-poned. Next day the swelling showed its true character by rupturing into the vagina and disclosing a very feetid abscess cavity surrounding the rectum. With the escape of the pus the tenesmus ceased. (3) While in charge of the Lock wards, I noticed that prostatitis was almost invariably accompanied by tenesmus. If of prolonged duration this produced a patulous condition of the anus, which might be regarded as due to recurring contractions of the bowel above. A similar condition of patulous anus was often seen in senile enlargement of the prostate. (4) A patient had been operated on for appendicitis some days previously. He became apathetic and drowsy, his temperature rose, his abdomen distended, and he ceased to have control of the bowels—small motions were constantly passed in bed. The anus was distinctly patulous. A diagnosis of pelvis peritonitis was made, and on opening the abdomen some very feetid pus was found; after its removal the patient made a rapid recovery.

This symptom—increased peristalsis—has been little noted by modern writers on rectal disease. Pott. in 1712, alludes to it, and in Pozzi's recent work mention is also made of it. It has been experi-

⁽a) Abstract of Paper read before the Edinburgh Medice-Chirurgical Society, March 1st. 1899.

mentally proved by Grünbaum (working under Nothnagel's supervision) that peritonitis increases peristalsis. He found that after the injection of chemical and bacterial irritants into the peritoneal cavity of the rabbit, active peristalsis was set up, and was not replaced by paralysis until twenty-four hours had elapsed. According to Treves, about 28 per cent. of all cases of peritonitis suffer from looseness of the bowels. Gee has suggested that the pain in colic and the pain in peritonitis were due to the same cause. I agree with this, and think that the pain in peritonitis is really colic; as soon, however, as the muscular coat of the bowel becomes inflamed, the colic ceases. When cases of severe abdominal pain come before me, the question I put to myself is no longer, Is this colic or peritonitis? but, as this is colic; to what is it due?

Clinical Records.

SECONDARY PULMONARY OSTEO-ARTHRO PATHY IN A CHILD. (a)
By Dr. R. Whitman,

of New York. A GIBL, &t. 8, recently came under my notice. She was rather undersized, but in fair physical condition. There was moderate kyphosis and rigidity of the spine, the result of Pott's disease of the tenth dorsal vertebra, accompanied by an abscess in the left iliac fossa, for which she had been treated by the application of a plaster-of-Paris jacket in 1893 when she was two years old. The abscess disappeared and the patient was re-covering favourably till 1896, when persistent cough and expectoration followed an attack of whoeping-cough. In 1897 enlargement of the fingers was noted, the gait was feeble and shuffling, and there was pain in the knees and ankles, with exaggerated patellar reflex and ankle clonus, and marked effusion into the knee and ankle-joints. The terminal phalanges and the nails were onlarged and there was cough with abundant expectora-tion and rales at the apex of the left lung. In 1898 the pain was relieved by the anti-rheumatic administration of salicylate of soda, and although there was a marked general improvement the swelling of the knees and ankles persisted, and the increased clubbing of the nails had attracted much attention, and was thought to be an instance of the so-called Hippocratic fingers, due to obstruction of the circulation caused by disease of the lungs. Expectoration was moderate in amount and bacilli were not found. In October, however, an examination showed thickening and enlargement of the bones of the lower arms and sensitiveness to pressure and swelling of the wrist joints. This made the diagnosis clear, and at once connected the clubbing of the fingers, the arthritis, and the enlarged bones as symptomatic of the affection known as secondary pulmonary hypertrophic osteo-arthropathy. The child was found to have no psoas contraction or other trace of abscess, and there was apparent recovery from the disease of the spine. There was slight dulness at the apex of the left lung, and increased respiratory sounds at the base of the right. The most marked peculiarity was the great size of the hands as compared with the size of the child and of the lower arms and legs as compared with the upper segments of the extremities, giving the impression of atrophy of the thighs and upper arms. The bones of the legs and fore-arms were sensitive to pressure. The knees, ankles, and wrists were enlarged by an effusion into the joints, and by thickening of the surrounding parts without redness, heat, or muscular spasm. Motion was very slightly limited. The digits were thickened, and their terminal phalanges remarkably enlarged with nails rose red in colour, but not especially thickened or curved. The circumference of the ends of the fingers and the breadth of the nails were twice as great as normal. This condition was somewhat less marked in the feet than in

(a) Abstracted by permission from notes of a case brought before the New York Academy of Medicine (Orthopædic Section), January 20th, 1899.

the hands. The affection of the bones in this disease appeared to be a form of malacia in which the organic material is somewhat increased, and the mineral substance, correspondingly diminished, so that the structure of the bone is weakened. The characteristic change is a deposit of new bone beneath the periosteum of the shafts of the phalanges, the metacarpal and metartarsal bones, and the lower part of the bones of the lower arm and leg with local sensitiveness, sympathetic arthritis, and clubbing of the ends of the digits and hypertrophy of the nails. The affection had been first described in 1888 by Bamburger and independently by Marie, who differentiated it from acromegalia with which it had been confounded. In practically all of the cases reported, upward of 80 in number, it was secondary to chronic disease of other parts, in 75 per cent. to tuberculous or suppurative disease of the lungs or its coverings. The cause of the periosteal and other changes was supposed to be the absorption of irritating substances from the focus of suppuration in or about the lung, combined with impaired circulation. Thus the first evidences appeared in the ends of the fingers. It was a rare disease, and this was believed to be the first typical case reported in a

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.
MEETING HELD THURSDAY, MARCH 9TH, 1899.

The President, Dr. H. Macnaughton-Jones, in the Chair.

SPECIMENS.

Dr. H. Jellett (Dublin) showed a specimen of myomatous uterus undergoing carcinomatous degeneration.

The President observed that cases of this kind were always of interest. He showed such a case some two years ago, in which the uterus was removed by vaginal hysterectomy. The patient lived for six months, and then she died; although no post-mortem examination was made, the probability was that she died of recurrence of this disease.

Dr. Inglis Parsons asked Dr. Jellett whether in this case the carcinoma began separately or was to be traced to a degeneration of the myoma. He had a case of this kind at the Chelsea Hospital for Women. She presented a polypus hanging from the cervix; and also had a carcinoma of the cervix; but whether the latter began independently, or as a degeneration of the myoma, he could not tell. But, in any case, such instances were a strong argument in favour of early removal.

Mr. Bowbeman Jessett believed that myomata take on malignant degeneration much more frequently than was generally supposed. When operated on early enough such cases did very well; and he hoped that a good result would follow in Dr. Jellett's case.

Dr. Jellett, in reply, said that when the operation was begun, by the vagina, the finger went through the uterus into the uterine cavity, as if through putty, while separating the bladder, and while separating the rectum the same thing happened; so he had to complete the operation through the abdomen. The operation took place in October, 1898; for two months she did very well; then she began to lose ground again, and he feared that at the present time she was already suffering from a recurrence of the disease.

Dr. Bantock read a paper on

THE MODERN DOCTRINE OF BACTERIOLOGY WITH SPECIAL REFERENCE TO GYNÆCOLOGY.

a full abstract of which appears in another column. The

paper gave rise to an animated debate.

The President said that no subject could be brought before any society more pregnant with interest or more important than that of the doctrine of bacteriology. It was important, not only to the gynecologist, but to the whole science and art of modern medicine, and therefore, now that it was before them, he was glad that there was such a large audience present. It would take a

whole session of their meetings to deal, even in outline, with the different points referred to in the paper, and therefore he would ask the speakers to confine their remarks to the bearings of the germ theory on gynæcology. There were two classes of observers present: first, expert bacteriologists who had spent their time on the study of the life-history and morphology of micro-organisms in all their bearings, physiological and pathological; second, those, more numerous but whose evidence was not less important, who, in their practical work, had put the views of the experts to the test. So, in order to make this discussion of greater value, inasmuch as the reports of it would go out to the whole world, their Fellows including gynecologists of note in every civilised country, he would ask those present to address themselves to one of the two attitudes he had mentioned. He would first call on Dr. Allan Macfadyen, Director of the Jenner Institute of Preventive Medicine, to address the meeting.

Dr. MACFADYEN remarked that he had attended the meetings of many scientific and medical societies, but it was the first time that it had fallen to his lot to his lot to such a paper as had just been read by Dr. Bantock before a society of repute. It was a unique experience that in the country which produced Lister such views should be held and put forth. He had come prepared to lister to and take part in, a serious discussion. The exwas the first time that it had fallen to his lot to listen to perimental research of the last ten years did not appear to exist for Dr. Bantock, nor had he brought forward one word of proof for the statements he had made. It was difficult to appreciate or to deal with such a mental attitude of pure negation, and he therefore abandoned any hope of convincing Dr. Bantock, and felt it would be useless on his part to bring forward in connection with such a paper the remarks he had intended to make upon the bacteriological questions pertaining to asepsis and antisepsis. Dr. Bantock had asked, "Where did the germ theory of disease stand now?" He replied that it stood exactly where it did before Dr. Bantock commenced his attack. What they had listened to was simply a "confession of faith"—and nothing more. He would not indulge in any comments upon opinions brought forward without any basis of experimental proof or fact, but would leave it to the members of the Society, who were well acquainted with the elementary facts of bacteriology, to make their own choice as to whom they would follow, Pasteur, Lister and Koch or Dr. Bantock. Dr. Macfadyen concluded that if he were a guest of the Society on some future occasion he would be pleased to discuss the questions raised in a more serious fashion than they had listened to that evening.

Dr. STOKER said he had listened to Dr. Bantock's interesting paper with great attention. Dr. Bantock had travelled over a very wide field, into many parts of which he (Dr. Stoker) was quite unable to follow him. He (Dr. Stoker) proposed to offer a few remarks in reference to his own work as to the effect of staphylococci in wounds, &c., treated by oxygen gas. He felt he was placed between two extremes, on the one hand it was stated that all micro-organisms in wounds were bad, and on the other that none were bad; he stood midway, and believed that some were harmful and some useful, and of the latter were the staphylococci. It was a perfectly reasonable belief that certain micro-organisms under healthy conditions were good and useful, and that these same bodies under unhealthy conditions were harmful, and that was his view abutt staphylococci. They were to be found all over the body, both on the surface and elsewhere; as long as the parts containing them were normal they carried out their functions, but if, for instance, the skin were cut or bruised then pus formed, because the conditions were altered, owing to the equilibrium established by parture having been usest by the scaledar. blished by nature having been upset by the accident. He (Dr. Stoker) said that he had made hundreds of observations on over 250 cases, and in all, rapidity of healing was in proportion to the presence of staphylococci. He quoted cases of sterile wounds and ulcers that had stopped healing; when put into oxygen these wounds after thirty-six hours were found to be plentifully supplied with staphylococci, and healed rapidly. He also quoted two cases and showed photographs of a girl who had a burn on her hand and one on her thigh. The

wound on the hand contained a plentiful growth of staphylococci and healed rapidly, the wound on the leg which had no staphylococci did not heal. The microorganisms were taken from the hand and placed in the leg wound which at once began to heal. These were facts, and not theory. His investigations were not carried out in any unworthy spirit of opposition to any theory or system that had been propounded. He was simply looking for the light, and to find the exact way in which oxygen produced its results.

Dr. R. T. HEWLETT remarked that any evidence given by Dr. Bantock in support of his views was entirely of a negative character, and negative evidence unless overwhelmingly supported was of little value. With regard to the Maidstone epidemic, Dr. Bantock was hardly fair; it was true that no typhoid bacilli had been isolated from the water, but Dr. Bantock omitted to mention that at least a month and probably six weeks had elapsed between the date of infection and the commencement of the examination. In other epidemics, notably that of Worthing, the typhoid bacillus had been isolated from the water. With regard to diphtheria, the diphtheria bacillus could be detected in the vast majority of cases. In splenic fever of cattle, the whole cycle of which could be observed in a lower animal, he could not conceive that anyone who read the history of the investigations into that disease could come to a conclusion other than that the bacillus anthracis was the causative agent. Tuberculin had been attacked, but he considered there were still cases in which it might be useful, and as regards risk that was inseparable from all forms of drug treatment. Lastly, Dr. Bantock had stated that as good results were obtained in ovariotomy from the use of ordinary cleanliness as with the most elaborate precautions for asepsis, but he would remark that the peritoneum was exceptional and would suffer with impunity a treatment which would be tolerated by no other serous mem-He believed that all attempts to open the kneejoint without the strictest antiseptic and aseptic precautions would end in disaster.

Dr. Inglis Parsons felt sorry that so distinguished a surgeon should hold such erroneous views on pathology. The results obtained by Dr. Bantock in his operations were against his own views, and in favour of the germ theory of disease, because he took the most scrupulous care to ensure cleanliness in his nurses, instruments, and surroundings, and thus by asoptic measures prevented infection. When there were no germs, antiseptics were not required. The Samaritan Hospital was comparatively modern and the surroundings were good, but in some of the older hospitals, unless strict Listerism was carried out, the results were disastrous. He could instance the practice of two surgeons when he was a student. One of them, using strict Listerism, was able to perform excision of the knee, and put up compound fractures, and open the peritoneum with impunity, while the other, who decried Lister, was obliged to give up these operations on account of the frightful mortality that followed. Such instances could be multiplied indefinitely. With regard to epi-demics of typhoid and other diseases Dr. Bantock had quoted one instance only where the bacillus could not be found, but he had omitted to mention hundreds of instances where it had been found and traced to a definite source of infection. He found it difficult to believe that Dr. Bantock seriously entertained these extraordinary views.

Mr. F. BOWREMAN JESSETT said he had had the privilege some years ago of witnessing Dr. Bantock do a number of abdominal sections. Dr. Bantock had most courteously also allowed him to see the patients with him when he dressed the wound. In several of them stitch abscesses had formed, and Dr. Bantock was in the habit of syringing these out with sulphurous acid. Mr. Jessett would like to ask Dr. Bantock if he still continued this practice, and whether he did not look upon sulphurous acid as a powerful antiseptic agent? He would also like to ask Dr. Bantock what, in his opinion, caused these abscesses? Dr. Bantock originally used silk for suturing the abdominal wound, but on account, as he (Mr. Jessett) understood it, of these abscesses, abandoned the silk for silkworm gut. Mr. Jessett would further like to ask Dr. Bantock if he now did not

boil all his silk before using? and pointed out that boiling or heat was admittedly the best disinfecting agent we had. Would Dr. Bantock explain why he boiled his silk? With respect to the typhoid bacillus Dr. Bantock had alluded to the Maidstone and King's Lynn epidemics. Did Dr. Bantock remember the Worthing and Caterham Valley epidemics? In the latter, two sides of a street were supplied by two different companies. On one side the inhabitants had typhoid, on the other they were free. On investigation it was discovered that the first case of typhoid occurred in a man who was working in a well which supplied the affected side, and he admitted that while working in the well, although then ill, he defected into it. Hence the epidemic. Could Dr. Bantock explain that?

Dr. Gobson thought it would be very disastrous if Dr. Bantock's paper had the effect of shaking the faith of midwifery practitioners in the employment of antiseptics. In an address which he had delivered to the Society when President, he had shown the marvellous change which had taken place in the City of London Lying-in Hospital in the death-rate since corrosive sublimate had been in use there. This was happily maintained, last year's annual report showing that only one death (from puerperal eclampsia) had occurred among the 565 women delivered in the hospital. There had not been a single case of septicæmia during the year. It would be indeed sad to revert to a mortality of 1 in 19, which existed when he first became attached to the hospital, and he had no doubt that the change was due to the thorough

way in which antiseptics were now employed.

Dr. Macphesson Lawbie declared himself an adherent of the germ theory of disease. Had Dr. Godson not referred to the subject, he had intended to recall to their recollection the remarkable paper delivered by that distinguished obstetrician before this Society. The facts brought forward by Dr. Godson furnished overwhelming evidence in favour of the antiseptic treatment of disease and he was somewhat surprised that none of the previous speakers had commented on those facts. He pointed out as a curious anomaly that while the extreme Listerites like Howard Kelly, and Lockwood, of London, emphasised the absolute necessity of adopting aseptic treatment in all its details, equally good results were apparently obtained by men like Dr. Bantock, who relied practically on soap and water. Such contradictions were very puzzling to the ordinary man who would be greatly helped if some definite rule of practice could be enunciated by such a Society as this, and he felt rather disappointed that some of the distinguished bacteriologists who were with them that night had not thrown more light on this part of the subject.
Dr. C. H. F. ROUTH remarked that the whole question

Dr. C. H. F. ROUTH remarked that the whole question was in a nutshell. Assume that the germ theory was nonsense: then how could they explain the fact that certain fluids coming in contact with healthy persons produced disease? How could they account for the phenomena of putrefaction? Some time ago he read before the Royal Medical and Chirurgical Society a paper on Puerperal Fever in Vienna. It was shown that in the department of the maternity attended by midwives the deaths were few, whilst in that worked by students there were 600 deaths a year. Semmelweis showed that the difference was due to the fact that the students went direct from post-mortem examinations to the maternity cases. How could they account for this except on the germ theory? Then they must remember that the causes of disease might be active at one time of the year, and not at another: this was a fact which cut the ground from under Dr. Bantock's feet. The plague in India was another case in point. Dr. Bantock ridiculed those who used antiseptic precautions; but he had not proved his thesis.

Dr. P. Z. Hebert asked Dr. Bantock what was the exact relation which he considered existed between disease and micro-organisms? He told them that bacteria were the result, not the cause of disease. This was a rather obscure statement. Disease was a condition, not a material entity. Did Dr. Bantock contend that bacteria were produced de novo by disease, or, in other words, was this a case of creation of something out of nothing? Or were bacteria formed out of the diseased

tissues? If not, where did they come from, since Dr. Bantock told them that bacteria were not to be found in the air. Would Dr. Bantock also give them his own-definition of what a sentic roison was?

definition of what a septic poison was?
Dr. A. W. ADDINGELL did not think that Dr. Bantock could congratulate himself on his powers of prophecy, because the doctrine of bacteriology held the field more triumphantly to-day than it did twelve years ago, when Dr. Bantook made his eloquent prophecy of its speedy downfall. There were many statements in the paper made without proof, i.e., in a negative sense, and as far as he could see there was only one statement made in a positive sense, and that was the reference to staphylococci in wounds. Dr. Stoker, like Dr. Bantock, explained the healing of wounds as due to the presence of staphylococci. The non-healing aseptic wound was said to have been treated with mercury, the strength of which was not stated. Granting the facts, Dr. Addinsell contended that the correct explanation was that the mercury had killed not only the staphylococci but also the granulations on which the healing depended. The other ulcers healed be-cause the oxygen favoured the granulations, and also diminished the virulence of the staphylococci. This view was proved by experiments in the laboratory at King's College where he had been working. It had been shown that though oxygen did not prevent the growth of staphylococci it did diminish their virulence, the proof of which was that a much larger amount of a culture of staphylococci passed through oxygen was needed to produce ulcers in guinea-pigs than was required in the case of a culture not so treated. Dr. Bantock seemed also to stumble over the gonococcus. He had told them about a washed gonococcus which did no harm when placed in a healthy urethra; but how could he prove that in the process of washing the gonococcus had not been in the process of washing the gonococcus had not been killed? Dr. Bantock disagreed with Dr. Newman in the latter's statement that the gonococcus caused pyosalpinx; there was no real difficulty in accepting Dr. Newman's view. It had been proved again and again that in a pus tube that had been removed the pus might be sterile, whilst a cultivation taken from below the surface of the pyogenic membrane was not sterile; thus affording scientific proof that under given conditions the gonococcus might lose its vitality.

Dr. HENRY JELLETT (Dublin) said that he had had the honour of discussing the question with the author about a year ago. He thought that Dr. Bantock neglected to pay sufficient attention to two very important points, when considering the question of the presence of bacteria in the human body without causing disease. The first of these was the difference in virulence of bacteria which were morphologically the same. He (Dr. Jellett) thought that accounted for the presence of strep-tococci in wounds and other places without giving rise to any symptoms of septic poisoning, although in other cases morphologically the same bacteria were un-doubtedly the cause of grave infection. The second point was the immunity acquired by patients to the action of a particular form of bacteria as the result of the continued presence in the body of that bacterium. He thought this explained cases in which the diphtheria bacillus was found in the throats of patients some long time after they had recovered from the actual disease. Then Dr. Bantock had talked of the slight degree of mischief brought about by the gonococcus as exemplified by the fact that they were only met with in one out of four cases of pyosalpinx. He (Dr. Jellett) thought that this was a very high proportion, if one took into account the number of cases of sterile, of undoubtedly tuberculous, and of presumably septic, pus tubes. In conclusion, he would like to ask Dr. Bantock two questions. First, why did he (Dr. Bantock) wash his hands, even to the slight extent that he did? Was it a species of ritual"? Dr. Bantock said, "That it was in order to remove what Lord Lister called the grosser forms of septic mischief." Dr. Jellett thought that in this case Dr. Bantock must either perform the washing solely as a tribute to Lord Lister and because he directed it, or he (Dr. Bantock) must believe in the existence of these grosser forms. If Dr. Bantock believed in the grosser forms which could be removed by any slight washing, why should he not believe in forms which required a more

Digitized by Google

scrupulous washing to remove? And if some people be-lieved in a slight washing, and others in a careful washing, and others in an antiseptic washing, he, Dr. Jellett, thought there was only a difference in degree of the same idea between Dr. Bantock's washing and other peoples. The second queetion was, supposing Dr. Bantock operated on a really septic case, as shown by the occurrence of high temperature, rigors, rapid pulse, &c., and that his hands were bathed in pus, would he operate on a non-septic patient the next day, or would he wait? If Dr. Bantock constantly went straight from a septic case to a non-septic case without any evil consequences arising, there was undoubtedly some cause to consider that his reasoning was correct. If, on the other hand, he waited for four or five days before operating again, Dr. Jellett thought that his hands would have had time to become sterile again, and that there was not the same reason to be astonished at his results

The President said he had been a strict adherent to the teachings of Lister from the days of the impermeable shellac with carbolic putty dressing to the present time, instancing cases which would have been unquestionably amputated by the older surgeons, restored to usefulness even by these old Listerian methods. The paper of Dr. Bantock, he said, bristled with contentious matter, but he—the President—entirely disagreed with the deductions which the reader had drawn. With regard to some of the matters touched upon, his eleven years' experience of epidemics in a large fever hospital, and in a Government Poor-law appointment outside it, as well as in a maternity institution, confirmed his belief in the teachings of bacteriologists. He altogether denied that the inferences drawn from the cases referred to by Dr. Bantock as occurring in Dr. Stoker's practice with oxygen on ulcers in any way refuted the germ theory of disease. Dr. Bantock was in opposition to the views of all the most distinguished living gynæcologists on the subject of the gonococcus and its relations to pyosalpinx. His views on antisepsis were entirely opposed to the practice and the teachings of surgeons for the last twenty years. The President ridiculed the idea of drawing those deductions, with regard to what Dr. Bantock called "cleanliness" in the practice of gynecologists, be-tween what he referred to as "the grosser forms of septic mischief" and the lesser. He was not quite correct in saying that micro-organisms had not been found specially associated with the pustulation of variola, and he overlooked the fact that those cases of scrotal surgery to which he had referred might possibly be accounted for by the condi-tions antagonistic to septic germs which were inherent in this part and in the testicular organs. Everything that Dr. Bantock had said with regard to the micro-organisms of the skin and their presence in wounds healing by the first intention was in accordance with widely known and acknowledged bacteriological facts. Given, however, sufficient aseptic preventive steps and resistant vitality on the part of the subject, and such micro-organisms were harmless. Such teachings as those enunciated in this paper set back the hands of the clock, so far as medicine was concerned, some five andtwenty or thirty years, and were all the more serious and dangerous because they emanated from one who was acknowledged to be a brilliant operating gynæcologist, and if endorsed by the imprimatur of that Society would go forth to the whole medical world, encouraging men who possibly had not his skill or favourable surroundings to pursue methods of operation which might prove most disastrous. In carefully listening to the paper, he, the President, could not help coming to the conclusion that Dr. Bantock had not made himself fully conversant with the researches of bacteriologists within recent years, or he would have been acquainted with the fact that the various questions which tended to make him sceptical, were by them fully and thoroughly discussed, such as that of the Klebs-Læffler bacillus, in its relation to diphtheria, the presence or absence of the gonococcus, the differentiation of the bacillus typhosus, and in fact, every question raised by him. The attitude of the Society to these views should be such that its verdict would be unmistakable, and that the British Gynæcological Society could in no way be involved by them.

Dr. Bantock, in reply, said he was very much disap-

pointed at the course the discussion had taken, for although two experts in bacteriology had taken part in it, no attempt had been made to refute a single point in his paper. They had not even referred to the oxygen treatment and its bacteriological results, which they evidently regarded as being unworthy of their notice. All the speakers avoided the points in the paper, and, while professing themselves followers of Lister, showed that they had taken no notice of his latest teaching, but adhered to that of twenty years ago. One of the bacteriologists accused him of disparaging Lord Lister, but the contrary was the fact, for he had gone out of his way to compliment him, and he was forcibly reminded of the legal advice "No case, shuse the plaintiff's attorney."
He was twitted with having studiously avoided the typhoid epidemic at Worthing. He could retort that his critic had equally avoided the Maidstone epidemic, as to which Dr. Poore substantially agreed with him in his Milroy lecture.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING RELD FRIDAY, FEBRUARY 3RD, 1899.

The President, Dr. D. J. COFFEY, in the Chair.

EFFECTS OF SODIUM CHLORIDE ON THE SECRETION OF URINE.

PROFESSOR W. H. THOMPSON read a communication dealing with the effects of minute quantities of sodium chloride on the secretion of urine. Solutions of sodium chloride (6.65 and 9 per cent. strength) were injected into the external saphenous vein of dogs in quantities varying from 30 c.c. to 5 c.c. Urine was collected from both ureters by means of cannulæ. The animals were given a hypodermic injection of morphine, and were ansethetised with a mixture of chloroform and ether (1 to 2) during the operative procedures. Urine was collected for definite periods of time before and after the injection of salt solution. The results showed:—1. A marked increase in the amount of urine secreted, which reached its maximum in the second hour after the injection, but had not wholly subsided even at the end of four hours. The average of ten experiments showed an augmentation of over three hundred per cent. 2. Both the total nitrogen and the urea also suffered an increase, though the urine secreted was more dilute. This augmentation reached its maximum in the hour immediately following the injection. The above effects were found not to be due to a dilution of the blood or hydræmic plethora caused by the injection, nor could they be ascribed to any supposed necessity for getting rid of the sodium chloride injected. In many cases the actual output of chlorides was diminished. No adequate cause has so far been found to account for the diuresis.

THE SENSORY DISTRIBUTION OF THE SEVENTH CRANIAL NERVE IN MAN.

The Secretary read for Professor Dixon, of Cardiff, a abstract of a paper on this subject. The views an abstract of a paper on this subject. which Prof. Dixon advanced may be summarised as follows:—1. The facial nerve in man is in a condition comparable with what is found in lower vertebrates. It clearly resembles in its distribution what has been called a typical branchial nerve. 2. The facial possessess two sensory branches—namely, the chorda tympani and the great superficial petrosal nerve. Both of these nerves are probably nerves of taste; the chorda tympani certainly is so, but this has not been definitely proved in the case of the great superficial petrosal nerve. The proved function of the corresponding nerve in lower vertebrates seems to justify the assumption that the great superficial petrosal is a nerve of taste also. 3. The fibres to which the term chorda tympani has been applied by physiologists do not form the chief part of that nerve; they do not represent the pre-spiracular nerve of lower vertebrates nor the corresponding nerve in man, which appears early, and passes into the developing tongue.

The President thought that the point of greatest value in Professor Dixon's paper was the definite state-

ment that fibres could be traced from the cells of the geniculate ganglion in both directions. This had, to his mind, established for certain that it is a sensory ganglion, and that both the prolongations must be sensory

Professor Symington said that with regard to the distribution of the chords tympani and the great superficial petrosal, on theoretical grounds he was in harmony with Professor Dixon. He attached more importance to the mode of development of these nerves than to any number of clinical observations or experimental work on nerves.

Dr. A. R. Parsons said if the course which the taste fibres take were known with certainty it would be a great aid in the localisation of disease. If the demonstration just given were correct, the question at once arose was the pars intermedia of Wrisberg to be looked upon as a continuation backwards of these taste fibres, and is the pars intermedia the nerve of taste of which the chords tympani and the great superficial petrosal are, to a certain extent, branches? If the great superficial petrosal nerve is not the motor nerve of the palate, what

The PRESIDENT thought it highly probable that the pars intermedia arises as part of the nucleus of the glosso-pharyngeal, and then the glosso-pharyngeal would be established as the nerve of taste.

The SECRETARY, in reply, said Professor Dixon did not hold it proven that the great petrosal is a nerve of taste, but he considered this view extremely probable. According to Professor Dixon's embryological researches, there ought to be no efferent vaso-dilator or secretory fibres in the chorda tympani nerve; if there are efferent fibres in it, they probably come from the sympathetic or some other cranial nerves.

Professor Symington exhibited four specimens of separate acromion process, which he had dissected, and discussed the question as to whether such cases are to be regarded as non-union of the epiphysis or ununited fractures, favouring the former view.

ANÆSTHETICS AND URINARY SECRETION.

Professor W. H. Thompson made a preliminary communication to this subject, of which the following is a brief summary: -1. A mixture of ether and chloroform (2 to 1) did not cause an increased diuresis. This was the anæsthetic used in his sodium chloride research. Six experiments were performed on dogs. 2. A. C. E. mixture on the contrary did, in most cases, markedly increase the amount of urine. In one case suppression was caused. This dog proved to have albuminuria. 3. Ether also produced an increase of urine, as did chloroform likewise, but with this latter anæsthetic only one experiment had so far been carried out. 4. Little or no effect was produced by the various anæsthetics on the total output of nitrogen and of urea, even in cases where marked diuresis was caused. 5. The after-effect on the output of chlorides showed a marked diminution. What the immediate effect was had not so far been definitely decided. 6. In eight experiments (with different anæsthetics) the urine was examined for carbohydrates with chloride of phenyl hydragin and sodium acetate. All but one gave crystals. Some of these were undoubtedly glucosazone, others glycuronic acid, while in one case it is probable the crystals were those of galactosazone. In all cases the dogs were injected with a solution of morphine.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD WEDNESDAY, MARCH 1st, 1899.

Sir John Batty Tuke, President, in the Chair.

THE following patients were shown:-

By Dr. Elder: (1) A case of absence of the first metacarpal bone (with skiagram); (2) a case of lupus vulgaris, which had developed shortly after vaccination, and had lasted for seventeen years; (3) an unusual example of amyotrophic lateral sclerosis affecting the lower extremities only, and causing double club-foot.

By Dr. Scot Skirving: Case showing double Charcot's

disease, simulating double congenital dislocation of the hip. Other symptoms of locomotor ataxia—the Argyll-Robertson pupil, absence of the knee-jerks, and lightning pains—were present.

By Dr. Scot Skieving and Dr. Cameron: A patient with total necrosis of the frontal bone, the result of syphilis. The orbital plates of the frontal bones were also gone; there was, in addition, a perforation of the hard

By Mr. STILES: (1) A case of infantile paralysis affecting the right hand and both legs. The lower extremities were completely paralysed below the knees, and dragged after the patient as he crawled about. It was proposed to do a double amputation at the seat of election; the muscular weakness of the thighs was too great to permit of a good result following excision of the knee-joints.

(2) A baby, aged seven months, with a very large hydrencephalocele implicating almost the whole cranial vault. It resembled, in fact, a case of hydrocephalus in which no ossification had occurred. (3) A child with coxa vera, which had greatly improved under the use of antirachitic treatment. Mr. Stiles thought that sur-

geons should not be in too great a hurry to operate on

these cases when they were seen early.

Mr. STILES also showed specimens of (1) viscera from a case of lympho-sarcoma of the abdomen. The symptoms had set in suddenly, and resembled those of abdominal tuberculosis. At the operation, the belly was found to be filled with small tumours, and the liver and spleen had secondary growths in them. The chief point of interest was that the patient had been supposed to be quite well up to five days before the operation. (2) The thoracic viscera of a child who had suffered from dyspnæs with excessive expiratory stridor. This was the third such case he had seen recently; tracheotomy had been of no avail in them. The symptoms—expiratory dyspnœa and absence of up and down movement of the traches—had in all cases been due to the pressure of enlarged bronchial glands. The reason why it occurred only during expiration was probably explained by the increased intra-thoracic pressure during the act.

Dr. Scot Skirving showed (1) sequestrum of the entire frontal bone; (2) microscopic specimens of tubercle of the mamma; (3) a compound fracture of the carpus

with comminution of the individual bones.

Mr. CATHCART exhibited a clinical research case, which contained within small compass all the requisites, including stains, a microtome, &c., for the examination of tumours. It was specially designed for the use of clerks and dressers working in surgical wards.

PERITONITIS AS A CAUSE OF INCREASED PERISTALSIS IN THE RECTUM, ETC.

Mr. C. W. CATHCART read a paper on this subject, an abstract of which will be found in another column.

Drs. Ronaldson, P. A. Young, and Cotterll discussed the paper. The last-named drew attention to the serious significance of diarrhoea occurring about ten days

after an otherwise satisfactory operation for appendicitis.

Dr. Chalmers Watson read a paper on "The Etiology of Gout." After mentioning some of the leading theories of the relationships between gout and uric acid, the speaker described some observations he had made on the seat of formation of uric acid. He had found uric acid in the blood of snakes and birds in greater quantity than in the kidneys. In mammals, he had found a very high percentage in the spleen, and a larger amount in the liver than in the kidneys. He had examined the blood of patients dying from various diseases not of a gouty nature, and had always found traces of uric acid in it. His results thus contraindicated those of Luff and Garrod, and led to the belief that the kidneys were not the seat of uric acid formation.

It is reported that the question of the right of licentiates of the Society of Apothecaries to style themselves physicians is not to be allowed to remain in the position established by the case of Hunter v. Clare, the Society having decided to take an early opportunity of reopening the matter.

Lunacy Department.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION. SCOTCH DIVISIONAL MEETING.

Dr. CLOUSTON in the Chair.

THE Spring Meeting was held in the Faculty of Physicians' and Surgeons' Hall, Glasgow, on Thursday, 9th inst.

Dr. Irrland read a paper on

THE CAUSES OF INCREASED FREQUENCY OF SUICIDE.

In his recent excellent paper contributed to the discussion of suicide at the annual meeting of the British Medical Association in Edinburgh, Dr. Sibbald expressed the opinion, and his statistics seemed logically to prove it, that there is no real increase of suicide at home or abroad. Dr. Ireland is inclined to dispute this statement, and the impression one gathered from his paper at the meeting in Glasgow was that he did not prove his case. He showed some excellent tables illustrating the numbers of suicides by different methods in Scotland for many years, and distinguishing between male and female suicides. He also showed an interesting table which compared the proportion per million in various European countries, showing a striking contrast between Italy at the lowest poll and Saxony at the highest. One very difficult question is to determine to what extent suicide is pathological, and to what extent deliberate, rational, and, as some would say, physiological. Statistics for different countries vary slightly, but in England there is a very considerable discrepancy, according to Wynn Wescott, who gives the pathological proportion at only 20 per cent., a very low rate indeed, and one which one is entitled to regard with some discredit. In regard to the question of causation, there are many points of view and many explanations. In the course of the dis-cussion which followed the paper, Dr. McPherson expressed his surprise that in Italy the number was so well, considering that, according to Lombroso, Italians are the most degenerate of civilised races. This statement of Lombroso's Dr. Ireland emphatically repudiated, being of opinion, from his own study of Lombroso's works, that the latter is guilty of many inaccuracies, and of none greater than this reflection on the physique and mental character of the Italians. Dr. Ireland does not believe in degeneration as a cause, nor does he believe, like so many pessimists, in the growing degeneracy of the race. He rather thinks, and we are inclined to agree with him that there is a gain of vigour and greater development seen among the youth of to-day as compared with a quarter of a century ago. In discussing further the causation of suicide, the author of the paper went into the various chief ideas pro and con, and expressed the opinion that the weakening of the religious sentiment in France has much to do with suicide. He summed up his idea of causation in one sentence, thus, greater sensitiveness, greater strain, less endurance, change of religious belief.

Dr. Clouston's contribution to the discussion dealt chiefly with causation under five heads, first, certain individuals are born with congenital absence of the love of life; second, melancholia and other forms of insanity; third, neuropathic, over-sensitive people; fourth, sympathetic, for example, couples commit suicide together, for example a man and his fiancée or man and wife, and this is especially noticeable in Paris, fifth deliberate

suicides.

Dr. Campbell Clark drew attention to the international differences as evidenced by the statistical tables and put some pertinent questions as to the explanation of these, particularly the great excess in Saxony over other countries. He drew attention to the selection of particular methods less painful in the case of women, and to the great discrepancy between the number of known suicides in the Clyde as compared with the number of persons found drowned.

Dr. McPherson, in reply to Dr. Campbell Clark, stated that Saxony was regarded as the most drunken country in Europe. This statement rather astonished Dr. Ireland, who gave it as his opinion that insanity in

Saxony was not greater than in other Continental countries. If this is so, it is rather an argument against the potency of alcohol as a cause of insanity.

Dr. CARLYLE JOHNSTON directed his attention chiefly to minimise if possible the value of the religious theory which he declined having anything to do with it.

Dr. Clouston thereafter gave a short statement regarding the Inebriate Act, and explained a scheme for the working out of it which he assisted in by drawing up regulations for the operation of the Act. These regulations apply for the present to what may be called the criminal inebriate, though perhaps the criminal is rather a strong term, but they will also do equally well for the non-criminal inebriate when an Act comes to be passed for him. They provide first for a State inebriate reformatory, second for certified inebriate reformatories set up by private individuals or local authorities; third, for licensing out of inebriates to respectable trustworthy families.

France.

FROM OUR OWN CORRESPONDENT.

Paris, March 19th, 1899.

PICRIC ACID.

Dr. There read, at the recent Surgical Congress, & paper on picric acid dressing for burns, in which he examined the toxic action of the drug. Could picric acid provoke grave symptoms of intoxication? That was a point he wished to discuss first, for although it was contested by a certain number of the members of the Congress, it had been affirmed so stoutly by others that if the fact were proved, picric acid dressing would lose the greater portion of its value. With all deference to the opinion of many esteemed colleagues, he would say from an experience of twelve years that never under any condition did he observe symptoms of poisoning from this dressing, and to furnish absolute proof that intoxication by the cutaneous surface, no matter how extensively denuded, was impossible, he would cite several cases where the salt was injected accidentally in considerable quantities without more than temporary injury to the patient.

The first case was reported by Prof. Halla. A patient swallowed by mistake a tablespoonful of picric acid. Vomiting, diarrhea, and a pronounced yellow coloration of the urine were the results. The stomach was washed out and the man recovered. A second case was observed by West (1896). A similar dose was absorbed. During the first twenty-four nothing abnormal was remarked; afterwards the urine became bloody and the patient jaundiced. Three days afterwards the patient was well. A third case was also one of Prof. Halla's. Here a teaspoonful of crystallised picric acid was taken. The symptoms observed were vomiting, diarrhea, urine coloured red, skin and conjunctiva yellow, pruritus and erythema of the abdomen and of the feet. The patient recovered rapidly. The fourth and last case he would cite was published by Karplus. The symptoms were the same as the preceding as well as the result. From these cases, in which enormous doses of the salt had been absorbed without permanent prejudice to the victims of the accident, it could be inferred that the simple dressing of a denuded surface by a solution of the acid was absolutely innocuous. The adversaries of this treatment accused it also of provoking such suffering that they had to abandon its application. He, on the contrary, found that it almost always attenuated the pain of the burns, and out of some thousands of

Digitized by Google

cases he had known it but once to produce such violent pain that it had to be abandoned.

In conclusion M. Thery insisted on the fact that the picric dressing should not be considered as a wet dressing, for in cases of burns wet dressing should be absolutely excluded. Immersion of the parts in a bath of picric acid, followed by a light cotton wadding dressing, was the best method when it could be applied. The application of any greasy substances to burns should be avoided on all occasions.

EXTRA-UTERINE PREGNANCY.

M. Pinard presented to the meeting of the Société de Chirurgie a woman in whom he had diagnosed an extra uterine pregnancy of six months in October last. He placed her under special treatment until the time when the child might be supposed to have a chance of living, and then operate. Christmas Day he extracted the child by incising the walls of the abdomen and of the cyst: he then sutured the wound and allowed the placents to eliminate spontaneously, and which arrived a fortnight ago. The child was doing well. That case, as well as another which he reported four years ago, showed that non-uterine children could arrive at a viable term more frequently than was believed, provided that the mothers were submitted to a special hygienic treatment, including absolute immobility. M. Guéniot said that extrauterine children were not always enclosed in a cyst; they were sometimes free in the abdominal cavity. He had a case of the kind, and where the placenta was grafted on the intestines. He extracted a living child almost at term, and to all appearances healthy and vigorous, but in spite of all the care taken it died on the fifteenth day. He considered that there was very little chance for children under those conditions.

Germany.

BERLIN, March 18th, 1899.

PECULIAR CASE OF INTESTINAL INCARCEBATION.—
TRAUMATIC GASTROCCTASY.—OPERATION.—RECOVERY.

Dr. Kohn publishes the following peculiar case in the Erst. Sachverstand Zeit., 3/99. The patient was a healthy man of 34, who had suffered from constipation in youth, who, whilst engaging in unloading a boat fell from the height of one or two metres, the right side striking bulwarks of the boat. At once there was pain and great difficulty of breathing, and soon afterwards constipation and frequent copious vomiting. Three years later, sudden spasmodic pain came on in the epigastrium and right side, obstruction, distension of the abdomen, the general condition being bad; in short, signs of internal strangulation. A striking feature was that the liver was pressed downwards, and tympany between the liver and the lung.

Gradually, under rest and washing out of the bowel, the tympany disappeared, and the bowels once more became free, and the general condition improved. Extreme dilatation of the stomach, however, still remained, the cause of which was subsequently discovered to be perigastritis. Laparotomy, which was performed, also revealed adhesive perihepatitis, with dragging of the liver towards the middle line. The relation of the train of symptoms was explained as follows:—The injury had set up perihepatitis and perigastritis. The latter rendered

the passage of food difficult, which led to dilatation of the stomach, which revealed itself the following year by the copious vomitings. By these acts of vomiting loops of intestine were forced into the pseudo-ligament between the liver and diaphragm, and hence internal strangulation. This was the rarest form of hernia, and had only been once before observed by Leichtenstern, and had been described by him as unique. Clinically it had been impossible to distinguish whether the loops of intestine had their seat above or below the diaphragm.

IMMEDIATE SUTURE OF VESICAL FISTULÆ.

In the D. Med. Zeit. is a reference to a paper on this subject by Dr. Stankiewicz. For a long time in cases of vesico-vaginal fistula he had been in the habit of suturing the bladder and the vagina separately. Proceeding from his own observations that wounds of the vaccinamade in colpotomy for instance, healed very rapidly, he at first paid greater attention to the vaginal suture, and took the greatest care in bringing the edges of the wound accurately together. Later on, however, he satisfied himself by observation that the walls of the bladder itself possessed the property of rapid healing, even if not to a great degree than those of the vagina, certainly not in a lesser. Further observation showed him that for closure of a vesical fistula accurate suture of the bladder walls alone was sufficient to effect the object. and that the vagina could be disregarded. In confirmation of this the author gives a number of illustrative cases, in which he has recently operated in this way with

Profection Against Infection Dueing Labour Prof. Doderlein (Berl. Klin. Wochensch., 50/98) convinced of the difficulty of always thoroughly disinfecting the hands of students about to examine a parturient woman, he attempted the use of the indiarubber glove of Friedreich. Since May of last year 200 parturient women have been examined by students, some of them as often as 30 or 40 times, and the experience gained has been in favour of the new method. The examining glove affords a protection against germs clinging to the hands, that cannot be assured by the most rigorous and careful disinfection, with the ungloved hand. The Professor intends publishing a further contribution on the subject shortly.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIEHEA, March 18th 1899. HYDROPATHY AND MALARIA,

WINTERNITZ, who is Professor of Hydropathy in the Vienna Faculty, has laboured assiduously for years past to place his department on a firm, reasonable basis. All the diseases human fiesh is heir to have been tried in succession, and the results noted with scientific accuracy in order that the principle of hydropathy may be generally accepted as a complete form of treatment and not a mere adjunct as it is at the present time in many countries. With this object in view Winternitz has taken different forms of disease seriatim; the latest being malaria which he confesses is not always amenable to the "water treatment." It seems from his history of this method of treatment that Currie and Glannini were the first to practise this curative form of water application, which was administered by them by pouring water over

the patient in the form of a douche. The latter records several cases of maleria he cured by dipping the patient in the water. Later Priessnitz treated malaria in a similar manner with equal success. After him Fischof treated 34 severe cases of pernicious malaria with only one failure, or 2.941 per cent. He administered sitz baths before the fever commenced.

Fleury seems to have added the largest number of success to our literature. He administered the cold bath from a quarter to half an hour before the febrile attack commenced at 12 degs. to 14 degs. Cent., 43.6 degs. to 47.2 degs. Fahr. This was applied as a douche passing through an aperture of 3 centimetres or 1.18 of inch. He treated 117 recent and chronic cases with quinine with very little benefit as he affirms in his writings. In 114 of these cases, after they had reached the malarial cachectic state, he commenced the hydriotic treatment with perfect success. Fleury had many imitators and opponents in his time, but was never induced to return to quinine for the treatment of malaria. Since 1859 the hydrotherapy has had many adherents. Winternitz reported several malarial cases in the Wiener Medizin Presse, of 1865, which he had treated successfully, while Mosler records others in the Wiener Medisin Wochenschrift for 1873, with equal beneficial results. Since that time Winternitz tells us he has treated 261 cases of quotidian tertiary and quartan fever, associated with the cachectic malaria, with 61 per cent. perfectly cured, and 39 per cent. improved. In acute tertian he had not 3 per cent. which were not permanently cured. In the whole literature 600 cases are recorded, with few failures.

Winternitz put before his class a case of acute tertian fever, which he said had been a failure under hydrotherapy. He is now inclined to believe the former cases were not correctly diagnosed, and were not genuine tertian malaria.

An example of a failure is given where quinine rapidly did what water would not.

He concludes very logically with the assertion that the water treatment raises the organic functions, increases development, and fortifies the natural defence of the body in warding off infection, while the antizymotic action is doubtless possessed by quinine by transforming the metabolism.

HYPERIDROSIS.

Kaposi exhibited a youth, æt. 15, who had suffered from partial hyperidrosis from childhood. When an infant the point of the nose was often covered with beads of perspiration.

As years passed this extended to the lips, ears, chin, and neck, as well as the flexor and extensor portions of the extremities. The anterior and posterior surfaces of the thorax as far down as the sixth rib are affected. During the last seven years the invasion has been low and circumscribed to small areas on various parts of the body.

The perspiration could be induced by a drink of cold water, while work or warm weather would check it.

The internal organs were perfectly normal but the nose, ears, fingers, &c., had a decided cyanotic appearance; and with the exception of a kyphoscoliosis appeared to feel perfectly well.

A peculiarity in this case was the irregular occurrence. The perspiration did not commence simultaneously on the nose, chin, and extremities, but rather in the order of citation.

Pilocarpin produced general idiosis; but if one arm was "ligatured" no sweating took place in that member till it was relieved, when immediately colossal drops of perspiration would appear. Atropin had the power of counteracting the effects of the pilocarpin.

Physiologically the sudstory secretion depends on two factors — vascular congestion and nerve influence. Psychical influences, such as fright and emotion are long known causes, but it is to Claude Bernard and Stricker our later anatomical knowledge is derived that the secretory nerves have their origin in the large ganglia of the cord. Injuring a mixed nerve will paralyse motor, sensory, and secretory action. Injury to the intervertebral ganglia will produce herpes to the spine or brain migraine, &c. In the same manner hemieplegic hyperidrosis is produced. The most common form, however, is the acro-hyperidrosis occurring in people with a low vascular tonus, such as the hands and feet. These usually have cold hands, dark red ears and nose.

In the case before us it is bilateral, and from the test with pilocarpin, central. In conjunction with scoliosis and other progressive symptoms, it may be diagnosed as hydromyelia in origin.

The Operating Theatres.

GUY'S HOSPITAL.

OPERATION FOR CONGENITAL HYPERTROPHY OF THE TONGUE.-Mr. ARBUTHNOT LANE operated on a boy, æt. 14, who had a very large tongue which protruded between his teeth, affecting his appearance and speech very prejudicially. Owing to all the air passing habitually through the mouth on account of its being constantly open the speech was rendered still more indistinct, and there was a constant discharge from the anterior nares which kept the upper lip in a very inflamed and hypertrophied condition. Excepting that the tongue was exceptionally large, it appeared and felt perfectly normal, and it had borne the same relationship to the surrounding parts since birth. A long triangular area having its base anteriorly was removed from the tongue, sufficient of the organ being left to represent its normal size and form. The triangular piece, which comprised the whole thickness of the organ, was cut out by means of sharp-pointed scissors, the raw surfaces of the lateral flaps being brought accurately into apposition by fishing gut and horsehair sutures.

It is interesting to note that the edges of the wound united so accurately that within a few days no evidence of any operation remained. The child had not learnt to control the new organs by the time he left the hospital, yet his speech was much more distinct than it had been previously to the operation, and he kept his mouth shut and breathed comfortably through his nose; the discharge from the anterior nares had ceased, and the upper lip had acquired its normal form and relationship to the lower. The stuttering from which the boy suffered originally. and which, as in stuttering generally, Mr. Lane said was due to a very imperfect respiratory capacity, is being steadily cured by exercises which increase the amount of air changed habitually by the patient.

OPERATION FOR SO-CALLED POTT'S FRACTURE.—The same surgeon operated on a young artilleryman, æt. 24, in whom the fibula had been fractured about an inch and a half above the tibio-fibular articulation, and the

Digitized by GOOGLE

nner malleolus had been broken through its base and dislocated outwards. The accident occurred in June, 1898, and he was invalided out of the service in January. 1899, as being physically unfit to perform his duties. He was quite unable to follow any occupation because of the pain he suffered in his foot and ankle when he walked, when the parts swelled up very much. Owing to the displacement of the tibial and fibular fragments the astragalus was rotated considerably round a vertical axis, so that its general direction was from behind, forwards and outwards. The tibial fragment was exposed and separated from its connection with the articular surface of the tibia; the fibular junction was also defined and cut through obliquely in a direction running from behind, downwards, forwards, and inwards in order to render it possible to rotate the lower fragment around an axis corresponding to the tibio-fibular articulation, so that the malleolus was brought forwards into its normal relationship with the rest of the foot; it was then retained there by wiring the fibular fragments together in their new position. Lane pointed out that in the forcible abduction of the foot upon the astragalus the external malleolus represents the fulcrum of a lever of the first order, the interval between it and the great toe forming the longarm, and the force exerted upon it is in such a direction as to tend to drive its lower extremity backwards. When the fibula breaks this tendency becomes an actuality, and while the tip of the malleolus is driven backwards and outwards the upper extremity of the lower fibular fragment is displaced forwards and inwards. It is because of this mechanical arrangement that such an adduction of the foot as is permitted by such an apparatus as Dupuytren's, or any other similar splint, serves no practical purpose in restoring the fibular fragments to their normal relationship to one another; there is, he said, no means by which force can be exerted on the external malleolus in a direction the reverse of that which is brought to bear upon it in the forcible and excessive abduction that produces Pott's fracture. It is on this account, he believes, that it is impossible to restore the fibula to its original form by any procedure other than operative. This, of course, he remarked, was purely a matter of personal experience, since there are many surgeons who assert without the slightest hesitation that they are able to restore the fragments to their normal relationship by manipulation and splints. He would like very much to know how this was done, as a large number of cases, some of which had been treated by surgeons of great experience, had come under his observation, but in these he was unable to find that the parts had been restored to their normal condition. The socalled Pott's fracture, he pointed out, differed in its mechanics from fracture of long bones generally, in that the resistance offered by ties shortened in their length by hæmorrhage and inflammation does not play an important part, the obstacle to the restoration existing in the fact that it is impossible to bring force to bear on the inner fragment in such a direction as to correct its displacement.

It is interesting to note that the progress of the case two weeks after operation is most satisfactory.

PROFESSOR STRUTHERS, whose death we recently recorded, has, we understand, left a bequest of £500 to the Glasgow University for Bursary purposes.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 22, 1899.

THE PATHOLOGICAL STATUS OF THE GENUS BACILLUS.

In the warfare against disease-producing organisms, we must assuredly not lose sight of the fact that they are, after all, but one factor in the production of disease; the other, and possibly the more important factor, being the impairment of vitality, constitutional or induced, permanent or ephemeral, which deprives the organism of the power of defending itself against the ubiquitous foe. There is indeed a danger lest, in studying the means of destroying the organism recognised to be intimately and constantly associated with this or that disease we may overlook the importance of arming the organism against the enemy, instead of merely slaying a few marauders. Moreover, a very small amount of experience is sufficient to show the practical impossibility of warding off a foe who lies in wait in every article of food, in every puff of wind, in every contact with the outside world. Unless the defenders are well organised, well provisioned, and fully equipped, the enemy will sooner or later gain a footing. The serum treatment from this point of view holds out vastly greater promise of a successful intervention than any system based on the employment of antiseptics, which of necessity must prove useless once the enemy has forced an entry. Serumtherapy has for object to impart to the organism an immunity or a capacity for resistance which it does not possess or has forfeited; in other words, it acts by rendering that organism an unsuitable milieu for the development of the particular microbe. This may be done without detriment to the organism itself, whereas antiseptics, to be of service, must be given in such doses that the hypothetical benefit which they

confer in one direction is more than compensated by the effects produced on the organism which they are intended to protect. But, it is urged, would it not be better to cultivate the natural means of defence rather than concentrate our attention on the enemy? This is precisely what the serum treatment does, and the method of treatment of feeding and reinforcing the defensive cells of the organism forms part of our everyday armamentarium. Certain individuals are born with a natural predisposition to particular diseases; in other words certain of their tissues do not possess the normal standard of resistance. If by serumtherapy we can remedy this constitutional defect, who will venture to affirm that we have not gained a march on the enemy? Therapeusis is essentially a biological rather than a chemical science. We cannot defend those who are utterly unable to defend themselves, though greater vigilance may, under certain circumstances, make up for inferiority of strength. If a person with weak lungs can be placed in surroundings free, as far as possible, from the means of infection, the predisposition remains a predisposition, and never becomes an infection. While, therefore, we may concede that the rehabilitation of the organism itself would, if practicable, be a more certain means of defence than the destruction of the attacking microbe, we must fully recognise that in proportion as we reduce the chances of an attack we increase the chances of escape of the organism in the unequal struggle. In the matter of tuberculosis this view is steadily gaining The present movement for the prevention of tuberculosis has a double object-first, to place the threatened organism under conditions calculated to stimulate and organise its powers of resistance, and secondly, to prevent the dissemination of the materies morbi. The progress already effected in safeguarding the purity, or failing that in the sterilisation, of articles of food, is incontestable evidence of our ability to circumvent the spread of this particular disease. While we by no means despise curative treatment, we must remember that treatment saves individuals, while prevention spares thousands. The serum treatment of diphtheria, for example, may reduce the case mortality, but until we can discover a mean; of preventing the spread of infection, we shall continue to register a large annual mortality from this cause. Beyond the fact that diphtheria is readily conveyed from one individual to another, we know little or nothing of the conditions which favour its spread, and it follows that, in spite of an improved and more successful treatment, it still ravages our youthful population.

MODERN SURGERY IN INDIA.

It is certain that not the least of the beneficent advantages resulting from our rule in India is the relief afforded to the suffering natives by the practice of modern surgery to which the well trained and able officers of the Indian Medical Service are able to give effect. India, of course, is a huge country with a

teeming population, the medical needs of which are almost entirely provided for by this department, and when we come to consider the statistics detailing the number of surgical operations performed upon the inhabitants in the course of a year, it is impossible to avoid being impressed with the stupendous nature of the work undertaken, and of the enormous amount of relief which must thus be afforded. In a recent number of the Indian Medical Gazette some figures appeared having reference to the work done in the Indian hospitals during 1897. The hospitals are of three classes, (1) State hospitals and charitable dispensaries, (2) local fund institutions, (3) private institutions. In 1897, throughout India, the number of patients treated in all the charitable institutions, numbering 2,055, reached the enormous total of 18,356,962. These figures are almost incredible, that is to say, even imagination almost fails to help us in understanding the magnitude of such a work Again the figures which relate to the number of surgical operations performed in certain of the provinces are scarcely less remarkable. For example we learn that in the Punjab 173,808 operations were performed in that province upon 171,419 patients, of whom no less than 164,164 were cured, and only Of these, 4,671 were for cataract, died. among which the percentage of success was 85.94. Again included among the operations were 1,811 for stone, of which 1,521 consisted of litholapaxy, with a mortality of 3.3 per cent.—a most excellent record. Lateral lithotomy was performed 249 times, and supra-pubic lithotomy upon only nine occasions. Furthermore, in Madras the surgical operations numbered 150,766, on 145,528 persons of whom 93.16 per cent. were cured, 5.52 temporarily relieved, and only 0.13 died. Included among these the operations for cataract and stone were remarkably few in comparison with those in the Punjab. Lastly in Bengal, excluding Calcutta, the surgical operations amounted to 135,505, with the result that 125,454 of the patients were cured, 6,542 relieved, 1,880 otherwise discharged and 216 died. The number of cataract extractions performed was 2,718 of which 2,206 were successful, 248 relieved, and 296 were failures A point of some interest is that 97 of the major operations in Bengal were performed by women practitioners, one of them being a native. These operations included 17 removals of tumours, 9 operations on bones, 1 amputation of the leg, and 48 extractions of the lens. We think we have now said enough to show what modern surgery is doing for the natives of our Indian dependency. Not only is relief being given to millions every year, and thousands upon thousands of lives saved by the aid of surgery, but every effort is made to educate natives, desirous of becoming medical men, up to the standard of proficiency required in the medical schools in Europe. Thus the native population in Indian have every reason for being grateful for the English rule, so far as these beneficent results are concerned. Nothing is more humanising than to relieve physical suffering, and nothing is likely to have such wide-spreading good effects.

ARMY MEDICAL AND PENAL ADMINISTRA-TION.

THE unfortunate death of a young soldier in Ireland has been under discussion in the House of Commons, where it can hardly have failed to open the eyes of legislators to the absolute need of reform in various directions more or less directly concerned with medical administration. The facts of the case, briefly summarised, are that a young trooper, recently enrolled in the 21st Lancers at Ballincollig barracks, had been punished for various consecutive minor military offences, and was pronounced to be fit for duty by the barracks surgeon, whereupon he was promptly sentenced to shot-drill and a further three days' imprisonment, but within two or three of that sentence he died. The unfortunate youth had a clot in the left ventricle, and appears to have been suffering from dysentery, a condition that was aggravated by enforced activity, want of proper medical treatment, and the starvation diet which this enlightened age still mortifies the flesh and enfeebles the will of transgressors. There can be little doubt that this unhappy soldier was practically dying all the while he was undergoing such senseless penalties as low diet, cells, and shot-drill, and that his technical offences were almost certainly the outcome of his physical condition. That being so, it becomes a matter of importance to make some inquiry into the administrative system that admits of the possibility of such barbarous accidents. So far as can be gathered from the reply of the Secretary for War, his chief palliative argument was that the deceased might have been sentenced to seven instead of three days imprisonment had his colonel not been mercifully inclined, and that the existing system was to blame for the low diet. It is to be hoped that the matter will not be set at rest by such meagre and unsatisfactory answers as those accorded by Mr. Wyndham, and that Parliament will lose no time in over-hauling both the penal system and the medical administration that could admit the possibility of occurrence as that reported from such an Ballincollig. As to the prison diet, simply indefensible to punish a man by depriving him of food, no less than it is unwise to goad him to despair by the imposition of shot-drill and other useless and degrading punishments. In a word, the aim of those responsible for military discipline should be to substitute rational and minimised sentences for the present excessive punishments, in many cases administered in civilian prisons. As to the medical aspect of the question, it was elicited in the House of Commons that the name of the local surgeon who declared the deceased to have been malingering was not to be found in either the Medical Register or the Medical Directory. The certificate, therefore, must have been granted presumably by an unregistered, if not by an unqualified practitioner. The Government have incurred a grave responsibility if they have entrusted the care of Her Majesty's troops to a man not on the Register, as averred by a medical member of Parliament.

incident will not be lost sight of when the Commons are invited to consider the new Medical Act, which has been for so long a time looming over the professional horizon. To detect malingering is an art that requires long practice, failing which the neophyte is apt to fall at any moment into errors that simply mean playing fast and loose with death. Hence the necessity for the Medical Officer engaged in the public services to be most wary in acting upon mere suspicion of that offence. Moreover, a confirmed malingerer may be overtaken with actual disease, and it is obvious enough that such symptoms as diarrhosa and a weak pulse require treatment, even when the result of the man's own machinations. In another case last week, where a recruit dropped dead on parade at Windsor, the condition of deceased's heart had been recognised by the brigade surgeon, who noted that it was in an irritable condition, and placed him under observation as a "special" recruit. Here, at any rate, the state of affairs was noted and precautions taken, so that the unfortunate issue may reasonably be regarded as unavoidable. With such facts as those we have discussed in this article before us, it can hardly be claimed by the War Office that the powers and administration of the Army Medical Department and the penal system enforced in the British Army are above reproach.

Rotes on Current Topics.

Fabrication of Vaccination Certificates.

THE trial and acquittal at Inverness of a medical practitioner on the charge of fabricating vaccination certificates has excited considerable interest in Scotland. It appears that while the accused was acting as medical officer of health for South Uist he transmitted to the registrar sixteen certificates of "successful vaccination," without having ascertained that the operation had been successful. The registrars. gifted with unusual prescience, had, however, only inscribed "vaccination," without the qualifying adjective, in their books. The whole evidence leaves a somewhat curious impression on the mind. The two medical witnesses for the prosecution agreed that there was no sign that the sixteen persons in question had been successfully vaccinated; they also admitted that they were unacquainted the effects of pin-point vaccination. One them thought that there ought to be some sort of a mark in consequence; the other said that it was quite possible to have successful vaccination leaving no trace behind it. For the defence, no less than six medical practitioners stated that they were in the habit of granting certificates of successful vaccination without seeing the patients, and solely on information from any," reliable person" that the operation had been successful. The case of the defendant appears really to have been a hard one. About the time that the alleged offences were committed he was acting as medical officer of health for the whole It is to be hoped that this island, over thirty-six miles long, with a population of nearly 6.000. A virulent outbreak of typhus took place, and according to the notorious custom of the western islander in the presence of epidemic disease, the inhabitants expected the doctor to perform some of the duties of an undertaker and nurse in addition to his proper functions. He was apparently over-worked, as only a country doctor is, and was highly complimented by the Local Government Board, while the local authorities were severely censured by the same body. According to his own evidence, the defendant ordered a school to be closed, exciting the intolerant wrath of the Bumbles of the district and leading immediately afterwards to his being relieved of his duties. A further point of interest is the fact that the warrant for his apprehension was granted by one of the medical witnesses for the prosecution-also an Honorary Sheriff substitute. It seems hard that the defendant should not only have been compelled to make four journeys at his own expense in connection with the case, but that he should also have been confined for two nights in the cells, to receive the somewhat tardy satisfaction of a unanimous acquittal by the jury (the jury has our respect) after an absence of three minutes, with the recommendation that all his expenses should be paid.

The Middlesex Hospital Medical School.

WEDNESDAY of last week was a red-letter day in the history of the medical school attached to the Middlesex Hospital, when a conversazione was held on the premises to celebrate some important additions to the educational facilities offered by this wellknown school. The new buildings consist of two blocks-the Gordon block and the Union Street block. The former comprises the large lecture theatre and the bacteriological research laboratory, the museum, the chemical department, with its appurtenances and dependencies, the pathological and bacteriological laboratories, the operative surgery theatre, and the dissecting room. The Union Street block comprises two physiological laboratories and several class rooms. The fittings and appliances throughout are thoroughly up to date, and reflect great credit on those responsible for the organisation of the details. A very large number of guests, lay and medical, put in an appearance during the evening, and many objects of interest awaited their inspection. Skiagraphy was well to the fore, and the exhibit of course comprised Dr. Mackenzie Davidson's ingenious apparatus for the localisation of objects. There was a large and varied series of museum specimens prepared by Dr. Voelcker by the Kaiserling method, and, further on, some very interesting microscopical specimens of yeast tumour, mycosis of the lung, &c. The band of the Royal Artillery discoursed sweet music in the museum during the evening, and altogether a very pleasant and instructive evening was spent. The excellence of the arrangements thus placed at the disposal of Middlesex students cannot fail to enhance the popularity of the school.

The Resignation of the Staff of the Seamen's Hospital.

THE announcement of the resignation of the medical staff of the Seamen's Hospital, at Greenwich, can scarcely be a matter of surprise to those who have followed the course of events in connection with the scheme of a Tropical School of Medicine for London. As a dignified protest against the rude and unwarranted treatment meted out to them by the lay authorities of the charity which they served. these resignations are both timely and natural. Moreover, in so doing, the staff have vindicated their honour both as gentlemen and members of the profession to which they belong. However, we fear that not much more has been attained. What do lay committees care for the susceptibilities of the medical staff attached to hospitals. It is well-known beforehand that, quite regardless of the circumstances. any vacancies upon hospital staffs which may be declared can be speedily filled. We do not doubt for a moment that this will be the case at the Seamen's Hospital. Even, perhaps, this committee counted upon their staff resigning when the full scheme of the proposed Tropical School was made known. At all events, it is quite certain that the staff in removing themselves have unavoidably played into the hands of the committee, for now the promoters of the Tropical School will have a freehand to make use of the Dreadnought Hospital in the furtherance of their scheme. Developments in this direction may now be expected. In marked contrast. however, to the reception of the proposal to found a Tropical School of Medicine in London is that accorded to a similar enterprise in Liverpool. In Liverpool the medical profession has taken the matter up most warmly, and with this stimulus to urge them on, the public have liberally responded. With the exposure, however, of the treatment accorded to the staff of the Dreadnought before them, we doubt whether the profession in London will ever give their support to the scheme, respecting which Mr. Chamberlain has so signally failed to accept good advice.

The Chloroform-Burglar Bogey.

LAST week our old friend the burglar of scientific: craft who lulls his sleeping victims into ansesthetic silence came boldly to the front in the Metropolis itself. Possibly the enterprising writer. feeling that the provinces had received sufficient notice, turned his attention to the great still unworked centre of civilisation and of enterprising journalism. At any rate he did not do the thing by halves, for he placed the chloroformist boldly in the midst of a medical man's household. circumstantial detail his narrative told how the servant going downstairs in the early morning found the place ransacked, and the doctor's trousers lying at the foot of the stairs. The maid then tried to rouse her master and mistress, but failed, and on entering the room, found them both suffering from the effects of chloroform: The theory is that the

burglars got a bottle of chloroform from the surgery and saturated a handkerchief, which they thrust beneath the door. The idea of being able to saturate the lower part of a room with this heavy anæsthetic vapour to the level of the sleepers in a bed by means of a single handkerchief and an ordinary stock bottle of chloroform is too ridiculous to discuss. This view we should be prepared to defend in the face of all comers. Meanwhile, should the story be maintained, we shall have the greatest pleasure in investigating the matter to its furthest confine. For us, this bogey of the burglar-chloroformist has always had a curious attraction, shedding as it does a halo of romance around an otherwise sordid calling. Possibly it may find now and then a rare use by way of veiled adver-Man is a curiously cunning animal in some of his intellectual developments.

Foreign and Colonial Graduates, Beware! THERE is a Bill now before Parliament which, although it has attracted but little public attention, will affect very materially the interests of Colonial and Foreign graduates in medicine. Its short title is the "University Degrees Act, 1899." It is backed by, among others, Sir John Lubbock, Sir William Priestley, and Dr. Farquharson. Its provisions are of an extremely stringent nature, and it is enacted that any foreign graduate who writes M.D. after his name, or who is responsible for the attachment of M.D. to his name, and who does not place and clearly indicate after such degree the source from which it has been received, shall be liable to be summoned before a court of summary justice and subjected to fine and various other penalties. No exception is made in the case of practitioners who are otherwise fully qualified in this country, and even the fact of the M.D. being registered as an additional qualification affords no protection. There are among us many men of good standing both in London and in the Provinces who have taken or have had conferred on them foreign degrees in medicine or science. Should this Act become law, and it is being pushed on very actively, such men as Sir Hermann Weber, Sir Walter Foster, Sir Felix Semon, and Dr. Dreschfeld, of Manchester, not to mention others, would be liable to prosecution simply for writing M.D. after their names. It is proposed that the Act shall come into force on the first of January next, and it will be retrospective in the sense that it will apply equally to graduates who took their additional qualification twenty or thirty years ago, and who have always used their M.D. both in public and private without interference. The Act is probably directed primarily against unqualified practitioners, and in that respect is commendable, but it is certainly very drastic and may easily be made the means of attacking the privileges of practitioners who have done nothing It either goes to deserve such treatment. If, for example, too far or not far enough. Sir Hermann Weber is to be rendered liable to prosecution for neglecting to inform the public that he is a graduate of the University of Bonn, why should not Sir William Priestley or Dr. Farquharson

be equally summarily dealt with for failing to indicate that their M.D.'s are of Scotch extraction? The University Degrees Bill was moved last week, but from accidental circumstances its second reading was postponed till a later day. It is understood that many medical graduates of colonial and foreign universities have written to members of Parliament with whom they are acquainted, urging their objections, and there is no doubt that there would have been a very determined opposition had the provisions of the proposed Act been more clearly understood.

The Petroleum Bill.

MR. RECKETT'S Bill for raising the flash point of petroleum to 100° F. was lost by a majority of eightyfive in the House of Commons last week, and the impression seems to be that this result was largely due to a statement by Mr. Healy, who remarked that the passing of the Bill would merely mean a change of the Petroleum tradefrom Rockefeller of New York, to Rothschild of Paris. There is no doubt that the whole question is being discussed not from the point of view of the public safety, but from that of the manufacturer. The struggle is one for trade supremacy-nothing more. The unanswerable fact remains that the American oil with the 73° F. flash point now sold in this country, is prohibited from being offered for sale in America. That is to say public safety in the United States is clearly considered to be of more moment than appears to be the case in England. The fact that the resolution to raise the flash point to 100° F. was only carried by a majority of one on the Petroleum Committee is quite immaterial. For some months current of public opinion has been gathering in favour of raising the flash point, and it would be best were the Government, despite Mr. Jesse Collings, to bear this fact in mind. Whatever the promise of the Government Bill may be, so far as its clauses relating to the construction of lamps are concerned. it is imperative that it should contain a clause raising the flash point to 100 deg. F.

The Phosphorus Report.

We are now in possession of the report of the Commission of experts appointed by the Government to inquire into the use of yellow phosphorus in the manufacture of matches. So far as the experts deal with scientific facts we are prepared to lend them our ears, but in other respects their utterances do not necessarily command respect. They do not deny the existence of "phossy jaw," but the tenour of the report is that its occurrence is mainly due to faulty methods of manufacture. This may be so though we have our doubts on this point, but the onus probandi in any case lies with the manufacturers. If adequate precautionary measures are of themselves sufficient to eradicate this disease from our midst it is impossible to exonerate the Government from serious responsibility in that these precautions have so long been neglected. It is not a question what manufacturers wish or do not wish nor even what

the public desire. If the yellow matches cannot be put on the market without exposing the workpeople to this painful, disabling, and even fatal affection then no Government worthy of the name would hesitate a moment in prohibiting its use. If needed it would be easy to allege many other reasons for discarding the use of matches that will light anywhere, notably the risk of fire, but these concern us not. We do, however, emphatically maintain either that regulations must be made and enforced which will render phossy jaw impossible, or else that the public must put up with the so-called safety matches. We trust as this is not a party question that our legislators will see that effective action is taken to improve this old standing scandal out of existence.

Medical Officers of Health and Tuberculosis.

As may be expected, the subject of the prevention of tuberculosis has aroused the enthusiastic attention of Medical Officers of Health throughout the United Kingdom. In many places, as for instance, at West Derby, the guardians have provided accommodation for phthisical patients in separate and special wards. They have not yet determined, however, upon the erection of hospitals for tuberculous persons above the Poor-law classes. The report of Dr. Felix Jones to the Llanfyllin Rural District may be taken as the type of scores that are being issued daily in all parts of the country. phasises the curability of the malady, describes the precautions necessary to prevent the spread of its specific infection. In short, it demonstrates for the behoof of the local populace how the preventible is to be prevented. All this energy cannot fail to be most reassuring to the apostles of public health, but it is to be hoped that they will not stop at the merely palliative measure of isolating and curing human beings, or as many of them as prove amenable to the latter attempt. What is needed to make good the logical claim of prevention is to attack the disease in the lower animals, especially those that contribute to the food of man. To regulate the butchers and the dairies, however, means an interference with vested interests, so that there will probably be time to discuss and investigate the matter at leisure.

A Declining Birth Rate.

FOR the last ten years the Registrar-General's returns have shown a perceptible decline in the birth rate in this country. In the first years of that period the rate never fell below 30 per 1,000 of the population; twice it rose to something over 31. In the last five years it has reached 30 per 1,000 only once, while last year (1898) it touched the lowest figure in the decennial period, namely, 29 4. From an Imperial point of view a declining birth rate is not a matter which can be complacently regarded by us as a nation, despite the fact that the shrinkage in number so far is not great. Nevertheless, we have the experience of our neighbours on the other side of the channel to prove that as soon as the birth rate of a nation steadily begins to decline, it goes on declining at a

rate which nothing can stop. Had the birth rate of last year been equal even to that of the five last years before it, the births in England and Wales would have exceeded the deaths by 371,530; as it was the excess was only 370,833. In this connection, however, it is not a little significant to learn that while the birth rate has declined the marriage rate has almost as steadily increased, so much so that in the Jubilee year, 1897, it touched the highest figure in ten years—namely, 16.0. These are facts and figures which, taken by themselves, do not perhaps convey much meaning to the ordinary individual, but their significance nevertheless cannot be overlooked. In truth, the Registrar-General's returns show that while in 1897 more persons entered upon matrimony than had been the case for the past ten years, in 1898 the birth rate was the lowest recorded for the same decennial period. Our readers may draw what conclusions they please as to these facts, but it would be difficult to explain them in accordance with natural

Life on a Rubbish Heap.

As we all know, a vast amount of sickness comes about in a mysterious manner, that is to say, no man knows whence it cometh. To discuss this subject would require a treatise, more or less, but there is one particular item that may be adverted to with the full and certain hope of instructiveness to be gathered therefrom. That detail is nothing more than the modern dwelling which is built upon "made" ground, the substance whereof has been built up by the slow increment of cartloads of ashes, rubble, manure, dust, dead cats, mud, ashes, and the rest of the multifurious abradacadabra of house refuse. The result of building on such a foundation that the body of the house, when draws up all the ground air, laden with noxious effluvia, and possibly with pathogenic bacteria. Of course, the provision of perfectly sound, impermeable concrete under the whole house would prevent the main part of the mischief. But how many suburban houses are thus provided? Not long ago the present writer, out of curiosity, went over some houses in the course of erection, the rent of them being from £70 to £80 per annum. The damp-proof courses were made of a kind of tarred paper, and the garden level was raised by a tight packing of wet clay, while the foundation of the hall space—that is to say, a long passage running through the house-was filled up with the same material. In that case life on a mudbank was substituted for that on a dust-heap, which we began by contemplating. By all means, let intending purchasers or tenants inquire carefully into the history of the sites of the houses in view, and let them have a skilled inspection made by a competent surveyor.

The treasurer of St. Thomas's Hospital, London, has received an anonymous donation of £1,000 for the endowment of a bed, to be called the "Tom Hughes Bed," in memory of Mr. T. Hughes, Q.C., author of "Tom Brown's Schooldays."

Heat in Hæmoptysis.

THE literature of hæmoptysis is voluminous, a remark that applies to a number of equally urgent symptomatic emergencies, but it has hardly yet attained the dignity of an exact and trustworthy therapeutic gospel. In other words, the logical chain has been weak in one or more of its links, and has not withstood the stream of practical experience. To take an illustration of the lack of knowledge of principle that underlies many of the physician's procedures, take that of the application of cold to the chest, a step that has been time out of mind the sheet anchor of the medical attendant. What more simple, what more reassuring to the patient and his friends, and we may now add in the light of modern wisdom what more ridiculous and ineffectual measure could be undertaken? Any candid medical practitioner who has had a fairly wide experience of hæmoptysis will probably admit at once that he can do little in severe cases even in the way of palliation. The stock remedies are gallic acid, styptics and ergot internally, with hypodermic injections of morphia, rest and the external application of ice. Sooth to say, it is not unlikely that we hitherto have all been wrong, and the proper thing is an application to the chest as hot as the patient can bear it. At any rate, many practical men do not hesitate to say that ice never yet stopped a had hæmoptysis. As the point is one of considerable interest and importance, some of our readers might be good enough to favour us with their particular views and experiences upon the subject.

The Parkes Memorial Prize.

The subject for the next Parkes Memorial Prize, which is open to Medical Officers of the Royal Navy, Army, and Indian Medical Services of executive rank on full pay (with the exception of the Assistant Professors of the Army Medical School during their term of office) is "Venereal Diseases in the British and Indian Armies: their Prevalence and Prevention." Essays, which must be illustrated as far as practicable from the personal experience of the writer, must be sent to the Secretary of the Parkes Memorial Fund, Royal Victoria Hospital, Calcutta, on or before December 31st, 1900. Each essay to have a motto and to be accompanied by a sealed envelope bearing the same motto, and containing the name of the competitor.

The Death of Major Evans, I.M.S.

WE regret to have to record the death of Major Evans, I.M.S., which occured on the 15th instant, at Calcutta. According to a telegram through Reuter's agency, he died from plague, contracted, it is believed, through making a post-mortem examination upon a plague patient. Dr. Evans was Professor of Pathology at the Calcutta Medical College, and his loss will make a great gap in the teaching staff thereof. He was, moreover, engaged upon some important investigations regarding the disease to which he has just fallen an untimely victim. Thus

another valuable life has been sacrificed in the cause of science and of the public good—and last, but not least—at the post of duty.

Secret Commissions.

THERE is no calling or profession in which the demoralising influence of secret commissions may not hypothetically make itself felt, and even in the medical profession it behoves us to be on our guard against the insidious practices complained of. Fortunately there is not much scope in medical practice for direct bribery of the kind with which the recent inquiry has made us familiar, but there are indirect ways in which, nevertheless, medical men might conceivably be interested in articles of commerce to the detriment of their professional honesty, such, for example, as the holding of shares in companies engaged in the manufacture of proprietary preparations and products, or of the thousand and one things which they might be tempted to recommend on other than strictly professional grounds. We do not believe, however, that even this attenuated and indirect form of corruption does, or has ever obtained in the ranks of the profession, and any obvious breach of this article of the unwritten code of ethics would entail upon the sinner social ostracism and professional ruin.

The New Polyclinic in London.

WE understand that matters are by no means going smoothly among the powers that be at the New Polyclinic, in Chenies Street, W.C. It is the same old story, a striving after the position, to use a vulgar expression, of "boss of the show." Thus two camps have been formed, one represented by a well-known surgeon, and the other by a specialist, and a struggle is now going on for the mastership. What the internecine discord will end in can hardly be predicted, but it cannot be good for an infantile organisation, such as that under discussion, to be exposed to the risks and disadvantages of disagreement among those responsible for its up-bringing.

THE Clinical Research Association, Limited, announces that it is launching out into a department which can only by a great stretch of imagination be connected with clinical research—viz., that of medical agent for the sale of practices and the supply of assistants. So many local authorities and other bodies now offer facilities for bacteriological investigations as a help to diagnosis that the need for such an association daily becomes less, though there must always remain a large, if narrower, sphere of useful activity open to it.

A DRAMATIC representation took place at Cannes last week, under the patronage of Princess Louise, for the benefit of the English hospital there, from which a considerable sum was realised for the charity. A second performance is to be given this week, when the Prince of Wales will be present.

PERSONAL.

Dr. Thomas Barlow has been selected to fill the vacancy on the University of London Commission, created by the resignation of Sir William Roberts.

Mr. ALEXANDER ANDERSON, Professor of Natural Philosophy in the Queen's College, Galway, has been appointed President of the College.

DE. KINNIER, of Saltcoats, having this month-completed his jubilee of practice in the town, the townsfolk have resolved to present him with a public testimonial in token of their esteem.

ONE among the small remnant of Lucknow heroes passed away last week in the person of Deputy-Inspector General Gee, V.C., C.B. He was present at the Relief of Lucknow, under General Havelock, and, on retiring, was made Honorary Surgeon to the Queen.

A REPORT has been extensively circulated in the Midlands that Dr. George Elder, of Nottingham, has retired from practice. We have the authority of Dr. Elder himself that, although he has resigned his appointment as Hon. Surgeon to the Samaritan Hospital for Women, owing to the pressure of professional work, he has no thought of retiring from practice.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE LORD RECTOR'S ADDRESS TO THE STUDENTS OF EDINBURGH UNIVERSITY.-Lord Balfour of Burleigh delivered his somewhat belated Rectorial address to the students of Edinburgh University on Tuesday of last week. His term of office is nearing a close, and that chief function, which forms the major part of a Lord Rector's duties, is usually carried out earlier in the day. Lord Balfour was at the same time made the recipient of an honorary degree of LL.D.—the first occasion, we be-lieve, on which a Lord Rector has delivered his address and been capped on the same occasion. The subject of the address was given as "National Character, and the function of the Universities in forming that character, and in preserving, developing, and strengthening it." An able and scholarly exposition of this theme followed, flavoured, excusably enough, by the addition of words in praise of the Universities of Scotland, their democratic characteristics, and the enormous influence they have exerted in the past, and possess at present, over the national thoughts and habits in Scotland.

WINTER SESSION MEDICAL STUDENTS.—The number of students attending the different courses in the Medical School of the Royal Colleges of Physicians and Surgeons, Edinburgh, during the closing Winter Session is officially estimated at 1,217. This represents an increase of 133 or 11½ per cent. over last year's figures. The classes end upon March 24th, while the Summer Session

opens on May 2nd.

VACANT CHAIR OF PATHOLOGY AT GLASGOW.—For the vacancy there is a large list of candidates, of whom there are some able men. A very strong candidate is Dr. Terry, of Aberdeen; another hails from Queen's College,

Belfast.

A TESTIMONIAL has been got up and numerously signed by the students at Gilmner Hill in favour of Dr. Lewis Sutherland, senior-assistant to the late Professor Coats, and who for the past two years carried on the work of the class. The students are anxious for and greatly desire his appointment to the vacancy.

A subscription list has been opened among the

members of the University Union to collect a sum of £20 with a view to placing in the Union buildings some permanent mark of esteem for the late Professor Joseph Coats, who took a very real and lively interest in the management of the Union, and who was its vice-president from 1891 till his death.

WINDFALL TO GLASGOW CHARITIES.—The late Mr. James Orr, of Harviestoun and Castle Campbell, has left to the Glasgow Royal Infirmary £2,500, to the Western Infirmary £2,250, Victoria Infirmary £2,000, Quarrier's Homes for Children, Bridge of Weir, £2,000, and to the following £250 each: Deaf and Dumb Institution, Glasgow. West of Scotland Seaside Convalescent Home, Lenzie Convalescent Home, Relief of Incurables, Asylum for the Blind, Glasgow, Maternity Hospital. In fact, to every charitable institution in Glasgow, and their name is legion. The Salvation Army comes in for the largest amount, viz, £5,000; this sum is to be the given to General Booth for the special use of the Salvation Army work in Scotland. A similar sum would have helped the University of Glasgow vastly, but there is no accounting for idiosyncracies. We must smile content for mercies as they come.

EPIDEMIC TYPHUS AT LEITH—Leith is at present suffering from a small epidemic of typhus fever. The outbreak appears to be quite limited, and, though the source of infection has not yet been traced, there seems no reason to suppose that it is in any way connected with the epidemic which visited Edinburgh some months ago. As a sea-port town, with a large immigrant population, Leith is peculiarly liable to outbreaks of infectious disease; smallpox was formerly common, and, up to quite recent times, typhus was almost endemic. It was not until compulsory notification was enforced, and suitable accommodation provided for fever cases, that this reproach was removed from the community.

THE Edinburgh (Lothians and Fife) Branch of the British Medical Association held a conjoint meeting with the Dundee Branch, on Friday last, in Edinburgh, at which numerous interesting clinical cases were shown, and demonstrations of special and new appliances, electrical, surgical, &c., given at the Royal Infirmary. The members then dined together, and, as usual, passed a very enjoyable sederunt.

Correspondence,

We do not hold ourselves responsible for the opinions of our correspondents. $% \label{eq:correspondents}%$

SYPHILIS IN THE ARMY, 1812-1898.—LETTER FROM DR. C. R. DRYSDALE.

To the Editor of THE MEDICAL PRESS AND CINCULAR.

SIR.—I notice that two distinguished physicians, Dr. Ogilvie and Dr. Shaw Mackenzie, have been good enough to refer to a little work of mine on the "Non-Mercurial Treatment of Syphilis," published in 1863; and, as that discussion throws some light upon the severe cases we hear of, of tertiary syphilis at Netley, perhaps I may be permitted to cite the passages from Dr Fergusson's "Notes and Recollections of a Professional Life," London, 1846, which has attracted the attention of these two able writers

On page 117 of that work, Fergusson thus wrote:—
"Until our experience in the Peninsular war there had been but one opinion among us of its (syphilis) utter incurability without mercury; and if by chance the disease got well without it, we had as little hesitation in declaring that it could not possibly have been syphilis, but some other disease putting on that form"

"On my appointment to be Chief of the Medical Department of the Portuguese Army, in 1810, I found that the native faculty never used mercury for primary symptoms, and very little, if any, for secondary ones; and they obstinately contended for the right and propriety of their conduct. Such infatuation, as I then thought it was, was not to be reasoned with. I applied to the Commander-in-Chief, and obtained the

Digitized by Google

strongest general order that could be penned, ordering the use of mercury in every stage of the venereal disease Still I was beat. Whenever I could not personally superintend, the remedy was neglected. At first the dislike and horror for the remedy was so great that they would rush from the room when it was applied, and wash it off with soap and water. In fact, I saw that I was playing a losing game, when I could not help myself; yet, at the same time, I could not help acknowledging that the gross consequences I apprehended must have ensued from their preposterous conduct did not follow; and that our soldiers who were mercurialised, I may say, to extremity, often suffered in a lamentable way. I now to make a scale of the applicability of mercury, I would say that the tithe of what formerly used to be administered is the proper initiatory quantity in any case until it is ascertained whether it suits the patient's constitution or not; that again, a tithe of that tithe, or a centime, is the allowable preliminary dose in secondary symptoms; for, wonderful to say, it seems to me to have been discovered that mercury was, after all, making its own work, by producing the very appearances of ulceration it was given to eradicate." On page 122 he wrote: "I shall conclude this part of my subject, at present, by stating the incontrovertible fact that the British Army at this moment contains thousands in perfect health, and has contained thousands more, who have been per-fectly cured of every stage or state of the syphilitic disease without ever having taken a particle of mercury"

Perhaps some of our present Army Medical Officers may interest themselves in this matter again; for I feel convinced that even yet, both in Aix-la-Chapelle and in London, and in our Army, some "heroic" practitioners still give far more mercury than is sanctioned by experience since Fergusson wrote. The introduction of iodide of potassium by Wallace, in 1836, has done away with all excuse for mercurial treatment in tertiary cases, and I am very sceptical of its use in any stage as a

germicide.

I am, Sir, yours truly,

CHARLES R. DRYSDALE, M.D. Late Phys. Rescue Soc. of Lond.

March 17th, 1899.

MEMORANDUM ON PROFESSIONAL SECRECY.

w of the Obligation of Medical Practitioners with Regard to Professional Secrect.

ON THE LAW OF THE OBLIGATION OF MEDICAL PRACTITIONERS WITH REGARD TO PROFESSIONAL SECRECY.

There are two aspects of the question of the professional secrecy of medical practitioners—namely, first, whether a medical man can be made to divulge professional confidence in a court of law; and, secondly, whether he may under any circumstances be permitted to divulge professional confidences in the intercourse of daily life.

1) As regards the first question, it is settled law that a medical man cannot claim the privilege, to which lawyers have been held to be entitled, of refusing to disclose matters communicated to them professionally. "A surgeon has no privilege, where it is a material question in a civil or criminal cause to know whether parties were married, or whether a child was born, to say that his introduction to the parties was in the course of his profession, and in that way he came to the knowledge of it. If a surgeon was voluntarily to reveal these secrets, to be sure he would be guilty of a breach of honour and of great indiscretion; but to give that information in a court of justice, which by the law of the land he is bound to do, will never be imputed to him as any indiscretion whatever"—per Lord Mansfield in the Duchess of Kingston's case, 20 S. T. p. 573. The same position is recognised by Buller, J., in Wilson v. Rastall, 4 T. R., p. 760, where he says: "There are cases to which it is much to be lamented that the law of privilege is not extended; those in which medical persons are obliged to disclose the information which they acquire by attending in their professional characters;" and similarly in a later case Lord Chancellor Brougham, after referring to a lawyer's right of privilege, continues as follows: "The foundation of this rule is not difficult to discover; it is not (as has sometimes been said) on account of any particular importance which the law attributes to the business of legal professors, or of any particular disposition to afford them protection; though certainly it may not be very

From these cases it is clear that a medical man not only may, but must, if necessary, violate professional confidences when answering questions material to an issue in a court of law.

(2) Upon the second question there have been, not unnaturally, very few expressions of judicial opinion. It is admitted as a general principle that a medical mrn should not disclose communications made to him in his professional capacity, and in the Scotch Court of Session it has been judicially decided that "secrecy is an essential condition of the contract between a medical man and his employers, and breach of secrecy affords a revelant ground for an action of damages," A.B. v. C. D., 14 Dualop, 2nd Series, 177. But upon this rule of the general inviolability of professional confidences (outsides court of law) the custom of the medical profession has engrated two exceptions (1) in cases of criminal communications, (2) where violation of secrecy is considered for the protection of wife or children (to which may be added a third exception, suggested by the Court in A. B. v. C. D., cited above, namely, instances conducive to the ends of science, though concealment of individuals should in such cases be secured). These two exceptions were the subject of testimony given by eminent medical witpesses in the case of Kitson v. Playfair in 1866, as being generally recognised among medical men, but they are not judicially recognised as invariable exceptions, as is shown by the summing-up of Sir H. Hawkins in that case. The defendant pleaded privilege on the ground of the second of the above exceptions, and though the point was not decided, owing to the judge is summing up: "The medical profession might, no doubt, discuss among passages are relevant to the matter of the obligation of screey among medical men. On medical evidence as to professional privilege being given, Sir H. Hawkins said: "The question of privilege and supplies of the profession of privilege of the ground of the season of the pudge summing up: "The medical profession mig

QUESTIONS SET AT THE LAST ARMY MEDICAL AND INDIAN MEDICAL EXAMINATIONS.

CHEMISTRY AND MATERIA MEDICA.

1. What is an alkaloid? What are the tests for (a) morphine hydrochloridum, (b) strychnina, (c) atropina? What official preparations contain strychnina, and what are their respective strengths. 2. How do you prepare oxygen? How would you administer it to a patient? 3. Give the official doses (for an adult) of liquor thyroidei, pepsinum, liquor trinitrini, tinctura camphore composita, pulvis kino compositus, scammoniæ resina, injectio apomorphinæ hypodermica. How is liquor thyroidei prepared? What are the constituents of mistura ferricomposita?

4. Describe the preparation of information of i composita? 4. Describe the preparation of infusum cinchonæ acidum, infusum digitalis, infusum gentianæ compositum, infusum scoparii, infusum senegæ, glycerium. 5. Give the formulæ for acidum sulphuricum, acidum sulphurosum, acidum nitricum, Explain how each may be made, and give the tests for each.

MEDICINE AND PATHOLOGY.

- 1. (a.) What points in the history and symptomatology of pneumonia—apart from physical signs (percussion, auscultation, &c.)—would enable you to diagnose that disease? (b.) Give, in tabular form, the differences in the physical signs in pneumonia in the stage of consoli-dation, and in fluid effusion into the left pleura.
- 2. A labourer, set 45, was admitted into hospital on September 4th, 1898. Four years previous to this he injured his right elbow-joint, which led to bone disease

with protracted suppuration. On admission it was found that several of the internal organs were affected. What was the probable nature of this disease? Enumerate the symptoms pertaining to each of these organs, and, in the event of a fatal issue, state in detail what you would find post-mortem.

3. Under what circumstances is cerebral disease likely to be followed by descending sclerosis? Indicate the path which the sclerosis follows, and give a sketch of the superadded symptoms indicative of that complica-

tion.

4. How would you treat typical cases of—(a.) Diabetes mellitus? (b.) The night-sweats of phthisis? (c.) An obstinate specific ulceration of the tongue of old stand-

NATURAL SCIENCES.

Geology and Physical Geography.

1. What is meteoric iron? In what situations does it occur, and how is its presence explained?

2. What are the chief strata in which fossil remains of (a) mammalia, (b) reptilia, (c) cephalopoda, occur? Mention examples.

3. What is meant by denudation? How would you recognise its effects on a tract of country? Mention localities where its effects may be seen in the British Islands.

Physics.

1. Describe the structure and uses of (a) the baroater, (b) the hygrometer. What are the peculiarities meter, (b) the hygrometer. of an aneroid barometer?

2. What is meant by the magnetism of the earth? Describe the structure and explain the action of the

Mariner's compass.

3. State Newton's laws of motion. Illustrate each by an example. Explain the following terms: -(a) gravitation, (b) tide, (c) temperature.

Botany.

- 1. Give the characters of the following natural orders: Labiatæ, Gentianaceæ, Scrophulariaceæ, Solanaceæ, Liliaceæ, Orchidaceæ Compare the structure of the flower of a rose with that of the flower of an anemone.
- 2. Describe the chief forms of inflorescence, of placentation, of vernation, of æstivation, and of roots, giving an
- example of each.

 3. Write a short account of the general structure of any flowering plant with which you are familiar.

Zoology.

1. What are the chief peculiarities of the fauna of (a) New Zealand, (b) Australia, (c) South America, (d) Madagascar, (e) Great Britain, (f) Ireland?

2. Write a short account of the development of the

frog from the spawn to the adult condition.

3. What are the chief peculiarities in the anatomy of (a) Camel, (b) Elephant, (c) Crocodile, (d) Rattlesnake, (e) Gymnotus.

SURGERY.

1. Give the pathology, symptoms, and treatment of rickets. What changes, immediate and remote, does it produce in a long bone, the femur for instance?

2. Describe a case of acute traumatic tetanus. Give the symptoms, pathology, treatment, and prognosis of the disease.

3. Give the causes, complications, and treatment of

entropion.

4. What abnormal conditions may be associated with an imperfect descent of the testis? Give their differential diagnosis, and briefly indicate the treatment of each:

ANATOMY AND PHYSIOLOGY.

- 1. Describe the manner in which the flexor tendons of the fingers and thumb are arranged in front of the wrist, in the palm, and in front of the digits. This description must include an account of the anterior annular ligament, of the flexor digital sheaths, and also of the synovial sheaths in relation to the tendons. Special value will be given to the practical points brought out in the description.
 - 2. Trace the vagus nerve through the neck and thorax

to its termination in the abdomen. Enumerate its branches and state the points in which the left nerve differs from the right. Have these differences in the relations presented by the two nerves any practical bearing in connection with aneurisms occurring within the thorax?

3. Within what area of the cerebral cortex do the nerve-fibres which form the pyramidal tract arise? Trace this tract in its downward path through the brain and spinal cord, and state how its component

fibres end.

4. Give the minute structure of a hepatic lobule, and state very shortly what you know of the "glycogenic function" of the liver.

Parliamentary Aews.

THE NEW CANTONMENT RULES IN INDIA .- In reply to a question by Major Rasch, Lord George Hamilton stated that the admission rate for venereal disease in the Indian Army was 485 per 1,000 in 1897, against 511 in 1896, a reduction of 26 per 1,000. The new rules were not brought into force until the end of 1897, which would explain the comparatively small reduction so far effected. Pending the reception of more circumstantial reports, he did not proposo to take any further action, adding that the returns for 1898, as far as they were at present known, were very encouraging.

SALE OF FOOD AND DRUGS BILL.—This Bill was read a second time, and a motion to refer it to the Standing Committee on Law stands over for discussion.

WATER GAS —In reply to a question by Mr. Ascroft, Mr. Jesse Collings stated that the recommendations of the Departmental Committee on the dangers of water gas were under consideration, but no decision had as yet been arrived at as to what action, if any, should be taken

THE STUDY OF TROPICAL DISEASES .- Dr. Clark having raised the question of the special study of tropical diseases, Mr. Chamberlain took advantage of the opportunity to make a statement on the subject. He explained his views and intentions on the subject with which our readers are by this time fully acquainted. The cost of this instruction would be provided partly by private subscription, partly by contributions by the Colonies, and the remainder by a grant in aid. He promised that men who had undergone a special course of instruction in this subject at other schools would receive a preference when making appointments for the Colonies, but he did not relinquish the safeguard that the candidates would also have to undergo the two months special training at the *Dreadnought*. The vote in aid was passed in committee.

THE SALE OF CABBOLIC ACID.—In reply to a question by Dr. Farquharson, Mr. Jesse Collings stated that, while the Privy Council did not think it expedient to include carbolic acid in the schedule of the Pharmacy Act, that body was opinion that regulations should be made with regard to its sale, and had prepared a Bill with this object in view. It was open to question, however, whether the Bill could be introduced during the present session.

CONTAMINATED OYSTERS,—In reply to Mr. Loder, Mr. Chaplin said he hoped to introduce a Bill dealing with the subject of contaminated oysters at an early date.

THE PROMOTION OF NAVAL MEDICAL OFFICERS.—In reply to Capt. Norton, Mr. Macartney said it was not thought desirable to alter the rules affecting the promotion of medical officers in the Navy, but directions had been given that when the time approached for the promotion of the officers who entered in 1878 to the rank of deputy-inspector general, their position on the list would be specially considered.

An inquest was opened on March 16th, at Southend, on the body of a woman who was stated to have been attended by a Madame Comber, who was described as a French lady doctor.

Literary Aotes and Gossip.

As far back as last August a Commission was appointed to compile a new Swiss Pharmacopœia, but it has never met as there was no money wherewith to pay anybody. That difficulty having been now adjusted, the meetings of the Commission will commence immediately.

MESSES. BAILLIERE, TINDALL, AND Cox announce as in the press an important work on "The Administrative Control of Fuberculosis," by Sir R. Thorne Thorne, Medical Officer to the Local Government Board. Also the Arris and Gale Lectures on "The Anatomy and Surgery of the Peritoneal Fosse," by Mr. Berkeley Moynihan, and a third edition of Sir William Broadbent's work on "Diseases of the Heart."

THE Medical Chronicle, which has been so closely associated with Manchester for many years, is to appear in a new dress with the April number. During the past few years it has been in the hands of the Medical members of the Council of the Owens College. It is now to be controlled by a committee of which Professor Leech is chairman. It is thought that under this new management the magazine will enter upon a career of increased usefulness.

WE understand that the "Irish Medical Directory" will not be published this year, the entire of the type and manuscripts for it having been destroyed in the recent fire which occurred at Messrs. Sealey, Bryers, and Walker, its printers. The Directory was started in the early seventies by Dr. A. H. Jacob, in connection with the MEDICAL PRESS, and was fairly successful up to the present. It had a predecessor of the same title which was published for a year or two in the forties by Dr. Henry Croly, of Rathfarnham, but was not continued.

UNDER the editorship of Drs. E. Besnier, K. Dehio, A. Hansen, A. Neisser, and Mr. Jonathan Hutchinson, it is proposed to publish a journal to be called the International Archives of Lyrosy, and it is believed that such a publication would be of great service in promoting the study and dissemination in an accessible form of the various points in connection with the disease which still demand inquiry. Those who are desirous of further information regarding the journal are invited to communicate with Prof. Albert Neisser, 11 Museum Strasse, Breslau. *.*

WE understand that Messrs. Green and Sons, printers and publishers, of Edinburgh, have projected an "Encyclopædia Medica," to be issued in twelve volumes, at twenty shillings each, net. It is intended to publish the first volume shortly, and to complete the series in three years. If the work be well done, we shall wish for it complete success, but with "The Twentieth Century Practice," of twenty volumes, in the course of issue, we fear the project to be somewhat venturesome. The fact is, the profession as a whole in this country are not rich enough, and those few who are have neither the space for, nor the time to read, these monumental works.

"Modern Dairy Sanitation" is the title of a booklet issued by Messrs. Welford and Sons' Dairy Company, Limited, in which are set forth the regulations carried out by that firm to ensure a milk supply of absolute purity, highest quality, and safeguarded against disease The booklet states that the company adopt the application of the tuberculin test to the milking stock, which ensures the supply being from healthy cows only, special attention being given in this respect to milk used for the nursery, and which is produced on their own farms. The cows are under the careful and constant observation of the company's veterinary surgeons, periodical examina-tions being made of the cows, and the whole system adopted by the company is one that should reassure the public that their interests are thoroughly safeguarded in the milk supply.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:-

BAILLIERE, TINDALL, AND COX (London and Paris).

The Pocket Pharmacopoia, including the Therapeutic Action of Drugs, their Natural Orders and Artive Principles. By F. Hudson-Cox, F.I.C., F.C.S., and John Stokes, M.D., M.E.C.S. Price 3s. 6d.

Aids to the Treatment of Diseases of Children. By John McCaw, M.D., L.E.C.P. Second Edition. Pp. 242. Price 3s. 6d.

Les Régenerations d'Organes par Le Dr. Paul Carnot, D.Sc. Pp. 96. Price 1 fr. 50.

The Administrative Control of Tuberculosis (Harben Lectures 1898.) By Sir Richard Thorne Thorne, K.C.B., F.R.S., F.R.C.P.Loud. Pp. 76.

DAM AND CHARLES BLACE (London).

The Pennycuik Experiments in Telegony. By J. Coesar Ewart, M.D., F.E.S. Pp. 177. Price 10s. net.

HENRY KIMPTON (London).

Elements of Alkaloidal Ætiology. Pp. 86. Price 2s. 6d. net.

H. K. LEWIS (London).

The Principles which Govern Treatment in Diseases and Disorders of the Heart. Lumleian Lectures. By Sir B. Douglas Powell, Bart., M.D. Pp. 118. Price 6s.
Treatment of Lateral Curvature of the Spine. By Bernard Roth, F.R.C.S. Second Edition. Pp. 14¹. Price 10s. 6d.

J. B. LIPPINCOTT COMPANY (Philadelphia).

An Experimental Research into Surgical Shock. By Geo. W. Crile, A.M., M.D. Pp. 160. Price 12s. 6d.

E. and S. Livingstone (Edinburgh).

Posological Tables, with Appendix on Poisons. New Edition. By Wm. Craig, M.D., F.R.S.Ed. Price 1s. net.

CONGRANS, GREEN, AND Co. (London).

Oxon. Pp. 272. Price 5s.

The Essentials of Chemical Physiology. By W. D. Halliburton, M.D., F.R.S. Third Edition. Pp. 199. Price 5s.

AMPSON LOW, MANSTON, AND Co. (London).

Twentieth Century Practice. Vol. XVII. Infectious Diseases and Malignant New Growths. Edited by Thos. L. Stedman, M.D., New York. Pp. 715.

MACMILLAN AND Co., LIMITED (London).

General Physiology: an Outline of the Science of Life. By Max Verworn, M.D., Ph.D. Translated by F. S. Lee, Ph.D., Columbia Univ. Pp. 614. Price 15s. net. JOHN MURBAY (London).

Kirke's Handbook of Physiology. Edited by W. D. Halliburton, M.D., F.B.S. Pp. 872. Fifteenth Edition. Price 14s.

KEGAN PAUL, TRENCH, TRUBNER AND Co. (London).

The Principles of Bacteriology. By Dr. F. Hueppe. Trans by Dr. E. O. Gordon, Univ. Chicago, Pp. 466. Price 9s. Translated

George Routledge and Sons, Limited (London).

The Microscope: Its History, Construction, and Application. By Jabez Hogg, M.E.C.S., F.R.M.S. Pp. 704. Price 10s. 6d. Fifteenth Edition.

SMITH, ELDER, AND Co. (London).

The Hunterian Oration. 1899. By Sir Wm. MacCormac, Bart., K.C.V.O. Pp. 60.

Growing Children, their Clothes and Deformity. By E. Noble Smith, F.B.C.S.Ed. Pp. 24.

SPOTTISWOODE AND Co. (London).

Minutes of the General Medical Council for the Year 1898, with 16 Appendices. Vol. XXXV. Pp. 707. Army Medical Department Report for 1997, with Appendix. Vol.

Laboratory Aotes.

HÆMATOGEN.

WE have received samples of Dr. Hommel's Hematogen, technically described as homoglobinum depuratum sterilisatum liquidum. Its basis is an organic and readily assimilable compound of iron especially adapted for the treatment of diseases and conditions in which the exhibition of a ferruginous preparation is indicated. In addition to the hæmoglobin, this product is stated to contain all the salts of fresh blood, as well as the serum albumen in its natural, i.e., undigested, form. It is a dark red, mobile fluid, with a sweet, somewhat astringent taste, in which a large proportion of iron is very perceptible. Its effects in cases of ansmia, after the bowels have been attended to, are very marked, and no difficulty is experienced by the most fastidious persons in taking it. It has been tried on a large scale in hospital practice in this country with very satisfactory results, having first been introduced on the continent with marked success.

"RISO FLOUR."

This is a good specimen of fine wheaten flour, and is conspicuously free from grit and indigestible fibre. It is self-raising, but it is nevertheless free from an undesirably high quantity of added mineral salts, the percentage of ash being only 1.4. The application of the logwood test showed the entire absence of alum. Microscopic examinations proved the absolute purity of the sample and showed its freedom from moulds or other objectionable matters. It is prepared by Messrs. Henry Roberts and Son, Mold.

CARBOLIC ACID SOLOIDS.

Carbolic acid, which still holds its own among the antiseptics at our disposal, is not very convenient of transport, and for this reason Messrs. Burroughs, Wellcome and Co., have been well advised in issuing the acid compressed into "Soloids." Each soloid contains a drachm of the acid mixed with a harmless colouring agent, and this serves to distinguish the solution from other liquids. One soloid dissolved in three-quarters of a pint of water yields, approximately, a 1/100 solution. Surgeons will appreciate the convenience of having this substance provided in a portable and readily soluble form from which any desired strength of solution can be promptly prepared.

SWAN WHITE FLOATING SOAP.

MESSES. LEVER BROTHERS, LIMITED, have added to their soap preparations a new product, which has been called "Swan White Floating Soap." As its name implies, it is of light specific gravity, and as such floats upon water. It is intended for washing delicate fabrics, and for toilet and bath use. From the sample sent us we can testify that the soap gives an exceedingly soft, quick lather, and is highly adapted for use in the nursery and for persons with tender skins. The soap is one of a high-class character and should soon become popular.

Medical Rews.

Diseases of Tropical Climates.

WE are asked by the Dean of the Medical School of St. George's Hospital to announce that a Course of Lectures will be delivered by Dr. Patrick Manson, on Tuesday, May 16th, and every succeeding Friday and Tuesday till July 18th, at 5 p.m. each day. The course is intended for medical men intending to practise in the Tropics or in Eastern Asia. It will embrace the fevers of warm climates, including malarial fevers, dengue, Mediterranean fever, and other unclassed varieties, dysentery, sprue, liver abscess, filariasis (elephantiasis, chyluria, etc.), ankylostomiasis, guinea worm, bilharzia and other parasites, beri-beri, tropical skin diseases, etc. The fee for the course will be three guineas. Application should be made to the Dean of the Medical School, St. George's Hospital, London, S.W., from whom cards of admission may be obtained.

Irish Medical School and Graduates' Association.

THE St. Patrick's Festival Dinner of this Association took place on Saturday evening last at the Café Monico, Sir William Thomson, F.R.C.S.I., president, in the chair, when a large number of members with their friends, including a large proportion of ladies, met to celebrate the occasion. Among those present were Sir George White, V.C., G.C.B., &c., the guest of the evening, Sir Wm. and Lady McCormac, Professor Alexander MacAlister, F.R.S., General Sir Thomas Gordon, Inspector-General William Lloyd, R.N., and Sir Dennis Fitzpatrick. After the usual loyal toast Professor MacAlister pro-

posed the toast of "Our Defenders," which was responded to by General Sir Thomas Gordon and Inspector-General William Lloyd. The toast of "Our Visitors," proposed by Sir William McCormac in a telling and muchapplauded speech, was responded to in a brilliant and enthusiastically received oratorical improvisation by General Sir George White, who feelingly defended the British Army against the insinuation that it could be regarded as a negligeable quantity. The intervals between the toasts were charmingly filled by various Irish songs, rendered by Miss Lilian Moreton, Mr. Douglas Powell, and Mr H. L. Fulkerson, while Miss Maude Jaque gave an exquisitely rendered violin solo. Needless to say that in such company a very enjoyable evening was spent, the charm whereof was greatly enhanced by the presence of the ladies.

THE MEDICAL PRESS.

The Dental Hospital of London.

The forty-first annual meeting of the Governors and friends of this institution was held on Friday last, when the Committee of Management were able to show in their report a slight increase in the amount contributed to the general fund during the past year and by exercising careful control over the hospital expenditure, whilst maintaining its efficiency, were able to transfer a considerable sum to the building fund. To place this fund in a satisfactory position, the report stated that it was absolutely necessary that £3,000 be raised during the current year, and the Committee very earnestly appealed for financial help. Donations and subscriptions may be sent to the Secretary, Mr. Pink, to the Treasurer, Joseph Walker, Esq. M.D., or to the Bankers, Messrs. Barclay and Co., Limited, 1 Pall Mall, S.W.

Mortality in Foreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Bombay 117, Madras 49, Paris 21, Brussels 25, Amsterdam 15. Rotterdam 20 The Hague 17, Copenhagen 28, Stockholm 20, Christiania 16, St. Petersburg 27, Moscow 24, Hamburg 17, Breslau 29, Munich 25, Vienna 25, Prague 28, Buda Pesth 30 Trieste 33, Rome-18, Turin (10 days) 21, New York 20, Philadelphia 22.

Vital Statistics.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 22.2 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year.

Birkenhead 22, Birmingham 17, Blackburn 21, Bolton 22, Bradford 21, Brighton 20, Bristol 20, Burnley 19, Cardiff 13, Croydon 16, Derby 19, Gateshead 13, Halifax 30, Huddersfield 18, Hull 19, Leeds 20, Leicester 21, Liverpool 28, London 22, Manchester 27, Newcastle-on-Tyne 28, Norwich 22, Nottingham 17, Oldham 29, Plymouth 21, Portsmouth 18, Preston 29, Salford 26, Sheffield 27, Sunderland 18, Swansea 16, West Ham 19, Wolverhampton 17. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 28 in Manchester; from scarlet fever 10 in Derby, and 12 in Salford; and from whooping-cough, 21 in Plymouth, and 27 in Birkenhead. In none of the large towns did the death-rate from "fever' or from diarrhea reach 10 per 1,000. The 93 deaths diphtheria included 36 in London, 7 in Sheffield, 5 in Leicester, 5 in Leeds, 4 in Cardiff, 4 in Liverpool, 3 in West Ham, 3 in Portsmouth. 3 in Swansea, and 3 in Salford. No death from small-pox was registered in any part of the United Kingdom.

Actices to Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Beader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS

AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS .- Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

INFORMATION WANTED.

WE are asked for information concerning Dr. G. H. Griffin, described as B.A., M.D., Montreal, who, in company with Dr. Anthony Hope, runs a "sure rheumatic cure" company, in Parliament Mansions, Westminster. We presume that our Canadian converse have their code of ethics and a medical council to deal with eocentricities, but we are, however, by no means sure that it is an offence, even in this country, to advertise in connection with a trading concern. What our own Council condemns is advertising with a view to practice, not advertising with a view to business or notoriety. Nevertheless, when a medical man goes into business, especially into the quack nostrum business, he would be well advised to relinquish the use of titles which imply that he is a medical practitioner. That, however, is a matter of taste and not of law.

House Surgeon.—The matter entirely rests with the coroner. He uses his discretion. If he thinks that an inquest is unnecessary an order for burial is issued forthwith.

ANTHROPOS.—The Ophthalmological Society of the United Kingdom is, we believe, the only one in London which has decided to admit medical women to its membership.

TRUE WORTH OF THE APPENDIX.

THE eminent surgeon closed up his pocketbook with a snap on the one hundred guines fee a wealthy patient had just paid him for a successful operation for appendictis. "Tell me the appendix vermiformis is a useless organ."—Public Health Journal.

D. P. H —Information upon the subject might be obtained by applying to the General Purposes Committee of the London County Council.

DR. Bernard T.—As the patient clearly misrepresented what our correspondent stated, no harm could be done by writing to the friends in order to correct the wrong impression.

PRESENTATION OF A GOLD CUP T) THE HON. T. H. BAYARD.

MR. HENRY S. WELLCOME has sent us an illustration in photogravure of the gold loving-cup presented to the Hon. T. H. Bayard, late American Ambassador to this country. The cup, which is 194 inches in height, is of solid gold, supported by American eagles with spread wings in sterling silver. Encircling the base is the Scriptural quotation, "On earth peace, good will toward men." The design is highly artistic, and is, we understand, from drawings made by Mr. Wellcome, whom we congratulate on having forged another link in the chain of Anglo-American brother-hood.

Dr. J. O'Kellt.—The subject is a delicate one to handle, and not free from the risk of a libel action. We are carefully considering the matter, and will deal with it in our next.

Meetings of the Societies and Tectures.

WEDNESDAY, MARCH 22nd.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. C. Stewart: Alternation of Generation, and Recent Additions to the Museum.

HUNTERIAN SOCIETY.—8.30 p.m. Mr. A. H. Tubby: Some Cases illustrating the Surgery of the Stomach. Dr. F. Fox: On Some Unusual Nervous Symptoms.

THURSDAY, MARCH 23RD.

THURSDAY, MARCH 23RD.

BRITISH GYMECOLOGICAL SOCIETY (20 Hanover Square, W.).—
8.30 p.m. Specimens will be shown by Mr. Jessett, Dr. Bantock,
Dr. Lawrie, Mr. Ryall, Dr. R. T. Smith, and Dr. Oliver. Paper:
Dr. J. Oliver: Adenoma Universale of the Eudometrium infiltrating
the Myometrium in a Virgin.

BRITISH BALMEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover
Square, W.).—8.30 p.m. Adjourned Discussion on Dr. D. Kerr's
and Dr. Hedley's Paper on the Therapeutics of Heat. Dr. WardHumphreys, Dr. K. Sibley, Dr. Bain (Harrogate), Dr. H. Campbell,
Dr. Felkin, Dr. A. Haig, Dr. Smith (Harrogate) Dr. B. Davies
(Llandrindod Wells), the President, and others will take part in the
discussion.

BOTAL COLLEGE OF PHYSICIANS OF LONDON —5 P.M. Dr.

ABSCUSSION.

ROTAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr.
Gee: The Nature of Asthma. (Lumleian Lecture).
ST. JOHN'S HOSPITAL FOR DIBEASES OF THE SKIN (Leicester Square, W.C.)—4.30 p.m. Dr. M. Dockrell: Cases of Rodent Ulcer and other Malignant Diseases of the Skin.

FRIDAY, MARCH 24TH.

BOYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. C. Stewart: Alternation of Generation, and Becent Additions to the

Museum.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m.

Papers:—Mr. J. Langton (President: A Case of Aneurysm of the Abdominal Aorts successfully treated by the introduction of Silver Wire into the Sac. Mr. Rutherford Morison: Patients showing results of Stomach Surgery, with descriptions of the Operations Performed. Dr. Radcliffe Crocker: A Case of Lymphangioma Tubercoum Multiplex. Mr. W. G. Spencer: Wound of a large Superficial Artery, is which the Blood was flowing from the Trunk to the Thigh.

MONDAY, MARCH 27TH.

ASSOCIATION OF ASYLUM WORKERS (Rooms of the Medical Society of London): -3.30 p.m. Annual Meeting, under the presidency of Sir J. Crichton Browne, M.D., F.E.S.

Dacancies.

Bracebridge Asylum, Lincolnshire.—Senior Assistant Medical Officer, unmarried. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Clerk to the Visitore, Bank Street, Lincoln.

Brixton Dispensary.—Besident Medical Officer for two years, unmarried. Salary £150, with apartments, attendance, coals, and gas. Applications to the Secretary, Brixton, S.W.

Chester General Infirmary.—Visiting Surgeon for two years. Salary £90 per annum, with residence and maintenance in the house. Applications to the Secretary.

Cumberland and Westmoreland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Derby County Asylum,—Assistant Medical Officer. Salary comp-

board and residence.

Derby County Asylum,—Assistant Medical Officer. Salary commencing at £100, with board, lodging, and washing.

Dinorwic Quarry Hospital.—Assistant to act as Assistant Surgeon. Salary £150 a year, with half midwifery fees attended by him. Applications to Mr. Roberts, Dinorwic Quarry Hospital, Llanberts, North Wales.

Parish of St. Leonard, Shoreditch.—Second Assistant Medical Officer for the Iufirmary, Hoxton Street, N. Salary at the rate of £70 per annum, with rations, washing, and apartments. Applications to the Clerk to the Guardians, £13 Kingsland Road, N. E.

Roxburgh District Asylum, Melrose—Assistant Medical Officer. Salary £100 per annum, with furnished quarters, board, washing, and attendance.

Appointments.

BATELY, JOHN, M.D.Durh., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Belton Medical District of the Mutford and Lothingland Union. BAYLIS H., R.C.P.Lond., M.B.C.S., House Surgeon to the Queen's

Lothingland Union.

BAYLIS H., R.C.P. Lond., M.B.C.S., House Surgeon to the Queen's Hospital, Birmingham.

CAVE, EDWARD J., M.D.Lond., M.R.C.P.Lond., Physician to the Royal United Hospital, Bath.

DAY, F. R., M.B., Ch.B.Vict., a Medical Officer to the Coventry and Warwickshire Hospital.

DEMPSEY, MARTIN JOSEPH, M.D. and M.Ch.B.U I., Demonstrator of Anatomy in the Catholic University School, and recently Assistant Physician to the Whitworth and Hardwicke Hospitals. has been appointed Physician to the Mater Misericordize Hospital.

DUNN, WILLIAM. M.B., C.M.Aberd., Medical Officer to the Mildenhall Sanitary District of the Mildenhall Union.

HOBDER, THOMAS J., M.B. Lond., M.R.C.P., Casualty Physician to Bartholomew's Hospital, London.

MALLAM, W. A., L.R.C.P. Lond., M.R.C.S., Out-door Medical Officer to the Eastern District of the Parish of Hampstead.

PERSHOUSE, F., L.R.C.P. Lond., M.B.C.S., Medical Officer to the Bradwell Sanitary District of the Maldon Union.

STONE, R. D. ALGES, L.R.C.P.&S. Irel., Medical Officer of Health to Kelston by the Keynsham Urban District Council.

TINLEY, W. E. F., M.D.Durh., B.S., L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer by the Whitby Urban District Council.

Council.

Todd, G. D., L.R.C.P.Edin., M.B.C.S., District Medical Officer to Selby and the Union Workhouse by the Selby Guardians.

Tubb, Thomas J.. L.R.C.P.Irel., L.B.C.Edin., D.P.H., County Medical Officer of Health for Withshire.

Walsh, L. H., M.B.Durh., L.B.C.P.Lond., M.B.C.S., Honorary Assistant Physician to the Boyal United Hospital, Bath.

WYLIE, D. S., M.B., Ch.B., Junior Resident Medical Officer to the Manchester Children's Hospital.

Births.

Boswell.—On March 13th, at Ashbourne, Derbyshire, the wife of Alexander Boswell, M.D., of a son.

Norron.—On March 14th, at Iddesleigh Mansions, Westminster, the wife of John Norton, M.D., D.P.H., of a son.

SAXBY.—On March 15th, at Halligarth, Shetland, the wife of Thomas Edmonston Saxby, L.R.C.P., L.R.C.S.E., L.F.P.S.G.,

of a daughter.

ITE.—(In March 16th, at the White House, Coventry, the wife of F. Faulder White, F.R.C S., of a daughter.

Marriages.

wdex—Scott.—On March 15th, at Benwell Parish Church, New-castle-on-Tyne, Robert Howden, M.A., M.B., Professor of Anatomy in the University of Durham, to Gertrude Mary, daughter of the late Alderman John O. Scott, J.P., of Benwell, Newcastle-upon-Tyne.

Peaths.

DEUTRY,—On March 19th, at 8 Strathmore Gardens, Kensington, Isabella, widow of Robert Druitt, M.D., F.R.C.P.Lond., aged 76.

JEE.—On March 17th, at his residence, Queniborough Hall, near Leicester, Dep.-Insp. General Jee, C.B., V.C., Honorary Surgeon to the Open.

Leicester, Dep.-Insp. General Jee, C.B., V.C., Honorary Surgeon to the Queen.

Keyworth.—March 19th, at 33 Augusta Piace, Learnington, Arthur F. Keyworth, M.R.C.S., L.R. C.P. Irel., of Beechfield, aged 38.

Budgs.—On March 19th, at Fakenham, Norfolk, Edward Drosier Rudge, M.D.

WILLIAMSON.—On March 18th, at Petherton Boad, Highbury New Park, N., James Williamson, M.D., aged 84 years.

.... Rectal

Suppositories

THE hermetically sealed sheath of pure tin-foil in which each 'Enule' Rectal Suppository is enclosed, acts as a protective against septic contamination or thermal influences. It is easily stripped off immediately before use.

THE improved shape makes insertion easy and renders expulsion impossible. The active principles are evenly diffused throughout each Enule' Rectal Suppository.

THE Glycerin 'Enule' contains 95 °/o of anhydrous chemically pure glycerin, and is free from gelatin. Like the other 'Enule' Suppositories, it will keep even in tropical climates, is readily soluble and prompt in action.

WITH COD LIVER OIL.

"As to diastaseconverting power 'MALTINE' is superior to the best Extracts of Malt I have ever seen."

Prof. STUTZER, Bonn.

"Clinical experience enables us to recommend it in virtue of its albuminoid contents and its richness in phosphates and diastase."

British Medical Journal.

In this preparation the nauseous taste and smell of the oil are perfectly masked by the pleasant flavour of the "MALTINE," and the oil is rendered thoroughly digestible by the breaking up of its globules into the minutest particles. By the process adopted, this subdivision of the oil is far more perfect than in any other preparation, the globules of oil being smaller than those of the fat in milk. The superior nutritive and tonic properties of "MALTINE," coupled with the fact that the whole of the oil is utilised by the system, make this preparation the menstruum par excellence for cod liver oil.

THE BRITISH MEDICAL JOURNAL points out:—
"Patients unable to tolerate the purest and most carefully prepared cod liver oil can readily digest and assimilate it when combined with 'MALTINE.'"

MALTO-YERBINE.

Bach Fluid Ounce of Malto-Yerbine contains the active principles of 30 grs. Yerba Santa. The fluid extracts of Yerba Santa have generally been found inelegant and unsatisfactory owing to the speedy precipitation of the resinoids, to which the herb owes its therapeutic efficiency. "Maltine," highly esteemed as the vehicle for many medicaments, exercises a peculiar subtile power of retaining in suspension the resins of Yerba Santa, as the albuminoids of "Maltine" attract and hold the minute resinous flakes and prevent their precipitation.

"MALTINE" with CASCARA SAGRADA.

Combined with "Maltine," Cascara Sagrada oscasions no griping, nor nausea, nor any distressing reaction, and the objectionable bitterness of the bark, so indifferently masked by other media, is overcome. The success of "Maltine" with Cascara Sagrada is largely due to the fact that in its preparation the fresh bark is selected with the greatest care and kept until thoroughly seasoned, while the extracts made from it are always tested for uniformity.

We shall be pleased to send Specimens Free of Charge to Medical Men.

In Prescribing, please specify "MALTINE COMPANY."

Original Communications.

NOTES ON THE PLAGUE.

COLLATED

By SIR CHAS. A. GORDON, K.C.B., M.D., Surgeon-General (retired), Hon. Physician to Her Majesty the Queen.

THE object with which the following Notes have been collated is to present to the readers of the MEDICAL PRESS AND CIRCULAR the gist or purport of information telegraphed from day to day to the Times with reference to the present epidemic of plague in India. The information thus obtained has been re-arranged under particular headings, so that comparison may be rendered the more easy, with the substance of reports already furnished, as well as with those which may hereafter be sent in. (Continued from page 584, December 7th, 1898).

Dr. Müller, who subsequently died in Vienna from laboratory plague, pointed out that the diagnosis between plague and influenza is extremely difficult at an early stage. In cases where pneumonia was present, it was not possible to decide whether it was the characteristic plague-pneumonia except by post-mortem examination. In three cases which they dissected, Dr. Müller's colleagues were unable to discover characteristic symptoms of primary bubo. He contends that Bitter has gone too far in asserting that the presence of bacilli in the blood indicates a fatal termination. A patient, he says, does not die because he has bacilli in his blood, or recover because of their absence. On the contrary, the question whether the organism will triumph over the disease depends upon the degree of its natural power of resistance to the poison of the plague.

Colonel Hendley stated that the plague at Selcori in 1897 was identical with the Pali plague of 1836. At Calcutta, cases of fever with enlargement of the glands were common, but indistinguishable from a mild form of plague except by bacteriological examination.

2. ENDRMICITY.

Colonel Weir thought that the disease was endemic in Kathiardar, North-Western Provinces, Bengal, and the Himalayas. Colonel Hutcheson stated that there had been periodical outbreaks of the disease called makamare in epidemic form for thirty years in Kumaon, Gathwal, and other places. The symptoms corresponded exactly with those of the plague, but he had not seen any pneumonic form. In Calcutta there was no reason to believe that the plague was endemic. The earliest cases in that city were among persons long resident in it, and it is improbable that they acquired the plague elsewhere. It was introduced by infected articles arriving by rail and sea.

8. LIABILITY TO ATTACK.

Males appear to be more liable to attack than women. The most liable age is thirty; the general period twenty to forty. At Bangalore there was no racial in-feriority. At Hyderabad the classes most affected were low-caste Hindoos. Mahomedans were not so liable to infection, nor were herdsmen who lived in the open air. Age and sex made no apparent difference. Mashar Husain, of the same place, stated that no case occurred among infants. At Calcutta mortality was high among the Christians, they being the hospital-going class. Of 98 cases admitted 80 died, of whom 69 were natives, only one Chinese, and one Burmese. There was no case among Africans.

4. SEASON.

In 1898 the Monsoon season lasted longer than usual, and the preventive measures adopted seemed less efficient during it. In 1897 the plague at Selcori began in December. At Calcutta, in 1898, the decrease of mortality from May to August was 3.5 upon the average of the same months in the previous five years.

The plague bacillus seems unable to propagate or even live for any length of time in sewers, where it is said to be destroyed by other bacteria. It soon perishes in the dead body, and in the excreta of patients. Light and air are in a high degree unfavourable to its development. At Bombay, Dr. Gibson stated that he had been experimenting for fourteen months, but had failed to find the (plague) bacillus in the floors of huts. In Calcutta, Major Charles said that the plague bacillus was found in the blood. The bacillus was imported in merchandise.

6. How Communicated.

Rats appear to be active agents in spreading the plague. But the chief sources of danger are contaminated clothes and bedding.

Mr. Vincent believed that the plague was introduced into Bombay by religious Asiatics from Kumaon, where he thought it was endemic.

Mr. Capel thought it was introduced into Hubli and

Dhanwar through the one way of human agency.

Mahdava Rao considered that it was introduced into

Bangalore from Hubli by goods and rats.

Captain Robertson, of Anantapur, traced the spread of the disease by human agency from the railway. Colonel Hendley considered that the infection was spread by human agency. At Calcutta, Dr. Cook was unable to find out the original source of the infection. At Baranul of the control of the contr saul only fifteen cases of infection were traced to Calcutta. At Calcutta the (plague) organism generally entered by abrasions of the hands and feet. No nurse or hospital attendant contracted plague, nor did friends of patients attending them in hospital. Two natives employed in the post-mortem room were infected and died. The method of infection was unascertainable from post-mortem appearances.

Major Charles believed that the contagion arrived (in

Calcutta) in bales of goods from Bombay.

7. By means of Water, Milk, etc.

At Bangalore, Mr. Slight said the milk was sent to large dairies where the cream was removed, and the milk was then resold to the cow owners, and distributed by them diluted with wells contaminated with subsoil drainage.

8. In RELATION TO ANIMALS.

Certain animals, especially rats, are liable to the disease. Colonel Weir was of opinion that in Bombay the disease was spread by rats. At Bangalore there was a large mortality from the plague among monkeys, squirrels, and rats. In every instance, after the first case among the population, increased mortality among rats was observed.

At Calcutta the disease was imported by sea and spread by rats from the landing jetties. Dr. Clemow considered that rats might produce disease in a house but not in a city. Dead rats frequently found in the streets during an outbreak were conspicuous by their absence. In seven cases out of 32 there was concurrent mortality of rats.

9. Anti-Plague Serum.

Dr. Haffkine said that his prophylactic was an arti-

Digitized by Google

Fragments of mutton are heated in hydrochloric acid to 284 degs. F. for six hours. residue is rejected, and the solution neutralised with soda. The heating partly chars the material. A small quantity of cocoanut oil is added, and the plague virus is inseminated. In a couple of days a stalactitic growth develops underneath the surface, the liquid remaining The stalactites are then shaken off and sink to the bottom, when a second crop develops. The process is repeated about a dozen times. The microbal vegetation incorporates with the organic matter. The process appears to take about six weeks to complete, but, unfortunately, the remaining portion of the telegram has been mislaid.

Dr. Balliotti, of the Royal University of Florence, described a process of making a curative serum which cured 75 per cent. of the patients treated. Major Deane declared that Yersia's serum was useless. He said that Haffkine's serum conferred a temporary immunity, but not to the extent supposed. Colonel McGana stated that Haffkine's prophylactic had been found valuable. Major Bannerman contended that it was cheap and effective, reducing the mortality 89 per cent.

According to Colonel Lawrie, of Hyderabad, Haffkine's fluid was not a serum, but a putrescent organic liquid containing micrococci of putrefaction, and occasionally pathogenic organisms. It was, therefore, directly against modern medicine and antiseptic surgery to inject the fluid.

He expressed his willingness to use Haffkine's fluid if it were rendered sterile, provided it was proved to retain its prophylactic power under those conditions. He admitted that the fluid, as now used, afforded considerable protection, but denied that it gave immunity. Sterilisation, he thought, might render it useless. Captain Johnson stated that out of six bottles of Haffkine's fluid living organisms had been found in five; the other was

Surgeon-General Harvey heard no complaints of blood poisoning after inoculation with Haffkine's fluid. Dr. Leumann inoculated 70,000 persons without ill-effects being produced. Dr. Cook, at Calcutta, had observed no lasting evil effects from inoculation. He had invariably found Haffkine's fluid sterile.

10. INOCULATION.

The statistics prove that a remarkable degree of immunity is secured by means of inoculation. But it would be wrong to enforce on an Indian population an experimental preservative which could not be rendered compulsory in an English city.

Surgeon-General Bainbridge was of opinion that sanitary and other measures should be placed before inoculation to combat the disease. Captain Childe had inoculated 400 people with Haffkine's serum, and had seen no bad effects. Mr. Capel said that the disease was very severe among the uninoculated; he found that Dr.

Haffkine's serum was beneficial.

Colonel Dobson stated that in Bengal more Hindoos were inoculated than Mahomedans, but there was a greater percentage of deaths among the Hindoos; the explanation was that Hindoos were poor and lived in worse conditions At Madras Colonel Kine was of opinion that inoculation was not a reasonable substitute for sanitation, but a valuable aid. Major Bannerman contended that Haffkine's serum was cheap and effective, reducing mortality 69 per cent. Numerous witnesses at Bangalore deposed that the same serum in the case of both English and native troops was satisfactory.

Drs. Mrs. Batten and Miss Livingstone described the inoculation of women and children among camp followers, which had a beneficial effect.

At Hyderabad inoculation had not been adopted. Other means were found satisfactory

Surgeon-General Harvey reported that the results of inoculation were most encouraging, of great service in combatting the plague.

At Calcutta an inoculated person was attacked.

Dr. Clemow inoculated fifty cases with Yersisis serum.

The results were negative. Thirteen patients were inoculated with Lustig's serum; ten died.

11. OTHER METHODS.

At Hyderabad, Masyhar Hassain stated that fair success was obtained by treatment with red iodide of mercury pills. At Calcutta Colonel Harris said that inoculative agents had proved beneficial. Alcohol stimulants were used.

12. SEGREGATION.

Captain Wilkins stated that the proportion of people attacked with plague after segregation was very

Captain Roe, chief police officer, Bombay, maintained that segregation was unsuccessful, owing to the difficulty of catching the people; if segregation were abolished, natives would not run away.

Colonel Benson, at Bangalore, stated that compulsory

segregation was objectionable.

Colonel Saunders, at Calcutta, considered that isolated segregation was a mistake, and contrary to the habits of the people. They were accustomed for centuries to segregate small-pox in their own houses, and would segregate plague similarly.

At Calcutta some cases were allowed to remain at home with no bad results, because of the means of segregation in the house. Contacts refused to go to the segregation There was no evidence that they carried infection. Colonel Russell thought there could be no parallel between small-pox and plague, with regard to segregation in houses, until inoculation for plague became as general as inoculation for small-pox.

13. DISINFECTANTS.

Superheated steam was considered to be the best disinfectant; perchloride of mercury and sulphuric acid came next.

At Calcutta, Dr. Cook had never seen a case in a disinfected house. Dr. Clemow stated that perchloride of iron was used as a disinfectant.

14. SANITARY MEASURES.

After all the measures of sanitation adopted in Bombay since the first appearance of the plague in that city the statement occurs that the disease is again increasing there.

Segregation, destruction of apparel and bedding, disinfection of houses, clearing out crowded quarters, and ample supply of fresh air and water are the measures most hopeful to keep the disease within control.

Surgeon-General Bainbridge considered that sanitary

and other measures should be placed before inoculation to combat the disease.

Captain Child said that the death-rate which usually preceded an outbreak of infection was high at Bombay in insanitary, and slight in sanitary, dwellings.

At Hyderabad the measures adopted were evacuation, disinfection, and the burning of floors and walls in kilns. The burning process was found satisfactory.

Mr. Stevens said that disinfection by burning in kilns destroyed all germs; no bacteria were found in the ashes; the plague never reappeared, and the villages were completely disinfected by the kilns.

Muscan Husani stated that in the Naldrug district corpses and their appendages were burnt where such a course was not forbidden by religion; in other cases dead bodies were buried eight feet deep. After evacua

tion of villages the fall in mortality was striking.
In the week ending Dec 19th, 1898, a further rise in plague returns was shown in Bombay city and district, and also for Madras and the Central Provinces. There was a considerable fall in the returns for Jussore.

At Bangalore plague has raged worse than ever it did in Bombay. It has attacked a British regiment in the first-named place. The barracks have been evacuated.

At Warahagarij evacuation was carried out very

thoroughly, and was successful in stopping the disease.

At Calcutta the measures taken were evacuation and disinfection. The plague stopped of its own accord. It was not affected by the measures taken. As the epidemic there advanced it became less virulent, though there was no abatement in the mortality. sanitary conditions had preserved Europeans.

15. STAMPING OUT THE PLAGUE.

The hope of stamping out the plague by means of sudden and violent measures must be dismissed.

16. NATIVE OPINION

The Indian press continues week after week to protest against a stringency of oppressive measures which could with difficulty be forced upon a European population, and which are so opposed to the most sacred traditions of Eastern life as to lead to armed risings wherever they have been insisted on.

At Bangalore, Colonel Robertson stated that the attitude of the people was uncompromisingly hostile; it was impossible in the large cities to deal effectively with the epidemic, the fear of which destroyed natural affec-

At Bombay the high priest of the Bohras explained that there were no religious grounds for objecting to inoculation as a preventive against the plague. The ex-Sheriff and his son having set the example, a large portion of those present at a meeting of inhabitants allowed themselves to be inoculated by Professor Haffkine and his assistants.

At Calcutta 200,000 people left the town out of a population of 700,000. Unscrupulous people fomented the panic. The greatest difficulty in dealing with the plague was the distrust with which the officers were treated.

The Harben Lectures.

THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS.

By SIR RICHARD THORNE THORNE. K.C.B., M.B., F.R.S., Medical Officer to the Local Government Board.

ABSTRACT OF LECTURE III.

Up to the present stage of these lectures I have felt no difficulty in expressing my views without reserve on the subject of the administrative measures which ought to be adopted in order to the control of tuberculosis. I have now to consider a proposal with regard to which I know that my views are at variance with those of some of the most distinguished members of the public health service of this country. I refer to the question of the compulsory notification of tuberculosis in man,

Applications have been made to the Local Government Board from time to time for their approval to the addition, at one time, of tuberculosis, at another, and more frequently, of phthisis, to the list of infectious diseases which are to be the subject of compulsory notification. Hitherto no such approval has been granted, and I can perhaps best approach my subject by giving some account of the considerations which that Board has held in view in refrain-

ing from granting the necessary approval.

At the outset, I would desire to express my entire sympathy with those who advocate compulsory notifica-tion of phthisis. If I cannot concur with some of my fellow-workers in their conviction that we can best save life and promote a higher standard of public health by this particular measure of control, it is because I feel certain that the compulsory notification of phthisis is calculated to retard the very object which they have in view, not only by alienating the public in regard to measures of prevention which cannot succeed unless they have the support of public opinion, but by placing insuperable hindrances in the way of that early treatment of the disease on which the arrest of its further progress and its cure are so largely dependent.

One of the first objections to the compulsory notification of phthisis under the Infectious Disease (Notification) Act, 1889, is that phthisis is a disease the inclusion of which among the infectious diseases to which that

Act applies was never intended.

Now all these diseases therein specified have special characteristics which lend themselves to notification, and to such restriction of the liberty of the subject as an be rightly demanded in the interests of the public. They are all diseases of an acute character, which, quite apart from the question of notification, renders it necessary to place certain restrictions on the sufferer for his own personal benefit. They all are diseases in which the infective stage is of a limited, and as a rule of very short, duration; and during a substantial portion of this infective stage the physical condition of the sick persons makes it necessary that they shall be under the control of those who are tending them, whilst for the remainder they are generally quite willing to be subjected to a control which, at the outside, will be of a few weeks' duration. And, again, they are all diseases in which the sick persons are, for an important portion of the limited time of their illness, unable, by reason of their physical condition, and notably by reason of their presenting obvious indications of their infective state, to take part in ordinary pursuits. These are conditions which justify the State in giving to those who are responsible for the public health and for preventing the spread of disease the power to require the notification to hem of the existence of such dangerous disease, in order that they may, for a few weeks, so control the sick persons to prevent their being a danger to others by the diffusion of their infection.

In the case of phthisis, however, we find not only that every one of those conditions is absent, but that, on the contrary, precisely opposite conditions obtain. Thus, phthisis is commonly a chronic, not an acute, disease, and it often happens that during a long term of years there is no reason, other than their opportunity of ejecting infective sputa, which can be urged for placing phthisical persons under any control or restrictions. Then, again, the infective stage is not limited to a few weeks, during most of which time the patients are, quite apart from their infectiveness, necessarily under the control of friends or relations, doctors and nurses. And lastly, it is commonly the case that, during a long period, perhaps extending to years, during which they are suffering from phthisis, the patients are physically able to perform the ordinary duties of life. In these respects, therefore, there is absolutely no parallel between the diseases named in the Infectious Disease (Notification) Act and the vast majority of cases of phthisis. On the contrary, the two sets of diseases stand in striking contrast. And the same want of similarity applies also to those infectious diseases which have, on the demand of the local sanitary authority, been added from time to time in a number of towns, either temporarily or permanently, to the statutory list of noti-fiable diseases, namely, measles, whooping-cough, cholera, and, in a few instances, that form of infectious diarrhœa in infants and children which is known under such names as epidemic or autumnal diarrhœa.

It is only right, however, whilst pointing out how phthisis differs in so many respects from the several diseases named, to state that it resembles them in one important respect, namely, that it is an infectious disease, communicable from person to person, and that in this sense it is, to use a statutory term, a "dangerous infectious disorder." But whilst this is so, yet it should be remembered, on the other hand, that phthisis as an infectious disorder differs from the other infectious diseases in the circumstance that the infection, instead of being almost entirely beyond control of the affected persons, is all but limited to the sputa, the disposal of which they can

A second objection to the compulsory notification of ohthisis has to do with the difficulty of ascertaining how far practical measures for its prevention can be applied as the result of such notification. The duty of approving or not approving of the addition of phthisis to the statutory list of notifiable diseases is one imposed on the Local Government Board by the Legisture: and hence that Board has the responsibility of deciding how far any such application is reasonable or not. With a view of determining this, it was at one time a not infrequent practice on the part of the Local Government Board to ask sanitary authorities who wished to make phthisis notifiable in their districts to inform the central authority in the first instance as to the precise action which they proposed to take on the information which notification would provide as regards a disease which might often last for a number of years, during which period it would

as a rule, be essential that the persons whose disease would be notified to them should be able to follow an occupation which would enable them to maintain themselves, and at times also to maintain a family. I have read a number of these answers, and I am bound to say that I never yet saw one which, in my opinion, would have justified the statutory approval which was asked for. Some authorities, indeed, appeared to find no answer at all, for the letter of inquiry brought the correspondence to a close. Others made it clear that they had never fully realised the import of their request; indeed, a number of them at once limited their proposal to the adoption of such measures as the disinfection of rooms, clothing, bedding, &c., after the death of any phthisical patients; and some of these explained the limitation to action after death by stating that it would be useless to the these states before about 1900 and be useless to take these steps before death because patients would be liable at once to reinfect the rooms and articles dealt with so long as they remained in contact with them. Action of so restricted a character does not appear to me to require or to justify compulsory notifica-tion of the disease; it could equally be carried out if deaths from phthisis were included among those deaths from infectious diseases of which so many sanitary authorities now obtain immediate information from the Registrar of Deaths for a trivial payment of twopence

At the other extreme, proposals have been made for the periodic visitation of patients at their homes, in order in the first instance to inculcate certain practices which are most desirable from the point of view of controlling infection. I refer to the giving of advice as to the avoidance of expectorating on floors or in the streets; the use either of special spittoons containing disinfectants or of special Japanese handkerchiefs, to be burned after use; the desirability of sleeping alone when this is practicable, &c. It is often proposed that on the occasion of these visits codes of directions embodying the necessary suggestions should be handed in in the form of leaflets printed by the local sanitary authority, and that both the patients and members of their families should be advised as to the conditions involving danger, and how these may be avoided. But a single visit of this sort is naturally deemed to be insufficient; it is hence to be followed up from time to time by other visits, in order to see if the directions given are or are not being carried out, to ascertain if the patient has removed to another residence, and in order to the adoption of additional precautions, including measures of cleansing and disinfection, either during the serious illness of the patient, or on removal to hospital or elsewhere, or, again, on the occurrence of death. Then, again, it has been stated by some authorities, who appeared to anticipate some difficulties in the matter of these visits, that they would only be paid, and the advice would only be given, in co-operation with the medical practitioner in attendance on the patient. A further proposal has been made—but in no case, as far as I know, by a local authority—that sanatoria should be erected under the statutory powers conferred on such authorities as to the construction, at the cost of the rates, of hospitals for the prevention of infection; and that revenue who are deemed by recess of pathicia to be that persons who are deemed by reason of phthisis to be a marked source of danger to their families and to the community should be induced to go into a sanatorium until at least they had been taught the several measures of precaution that they should adopt against the diffusion of their infection. of their infection.

Such measures, if they could be and really were carried out systematically for such a period—whether a term of years or less—during which they were required, could not fail to be of value in the prevention of tuberculous disease. But is it likely that they would be so carried out in this country?

Let us see how the demands which have been made as to this would be likely to operate if the statutory approval required by the Infectious Disease (Notification) Act were granted

We will assume the practice to be in operation, and that notifications of phthisis in its early stages take place among some of the hundreds of thousands of young men and young women who work in large houses of business,

and who, besides, are obliged to share their sleeping accommodation with others either in those houses of business or elsewhere. In the first place, they must be visited. But by whom? Some may answer, "By the Medical Officer of Health." But every such officer knows that even as regards the infectious diseases that are now notifiable, this has already become quite impracticable, not only in large centres of population, but still more so in those combined sanitary areas where medical officers of health have charge of eight, ten, or twelve sanitary districts, spread over areas at times as large as counties. The consequence is that even now this work has to be largely carried out by the sanitary inspectors; but I am certain that if this duty were so relegated as regards such classes as I refer to, very great friction would arise even if the inspectors acted under some general supervision of the Medical Officer of Health. Whether, however, the visit of inspection be paid by one or another officer, it will necessarily have to take cognisance of both the home and the place of occupation of the phthisical person; and the action taken, whether by leaflets or by personal advice, cannot fail to become known to fellow-employés, and in many cases to employers also. The justification for the demand that phthisis shall be compulsorily notified lies in the fact that the person in question is suffering from a dangerous infectious disorder communicable from person to person. Hence the question is already arising whether it is right to allow such a person to be in constant association with hitherto healthy people by day and still more so by night; and it is quite certain that the need for adopting special precautions as to sputa, &c., would lead to a large number of such persons being quietly dismissed from their posts. If such persons found fresh employment, they would certainly take care not again to afford any outward evidence of their malady by the adoption of the precautions urged on them in the interests of the public; and it is equally certain that they would to the utmost avoid consulting another medical practitioner, because their disease would again be notified, and precisely the same consequences that followed on the first notification might again be brought about.

Without following out such cases as these for several years, and to the bitter end, it will suffice for me to say that, in my opinion, a large amount of harm would result if phthisis were included in the list of notifiable diseases under the English Act. The certain knowledge that notification and the intervention of public officers would ensue would prevent resort to medical advice in the early stages of the disease, when its progress can best be arrested. The loss of employment consequent on notification would often tend, both physically and mentally, to deprive the ailing persons of their best, if not their only, chance of cure or improvement; for there are few diseases the cure of which is more dependent than is the case in incipient phthis on good food, wholesome surroundings, and freedom from mental anxiety. Indeed, it is of the first importance to a vast number of persons so suffering that they should be able continuously and without hindrance to follow an occupation sufficiently remunerative to keep them from any approach to physical want or anxiety of mind. Is this result likely to be brought about by the compulsory notification of phthisis? I believe it is not.

But objection may be raised to my line of argument. In the first place, it may be said that I have chosen by way of type a class of cases which presents exceptional difficulties. I am free to admit that this is, in some respects, true. But, on the other hand you would hardly expect that, when I was setting out the difficulties which would, in my opinion, follow on the addition of phthisis to the list of diseases to be compulsorily notified, I should try to exemplify my point by reference to cases which were most free from such difficulties. My point is to emphasise the difficulties and the mischief that might result from such notification, and cases such as, or in every essential respect comparable to, those to which I have referred would soon come to be counted by their thousands.

Or, again, it may be objected that even if all that I anticipate should come to be true, the hitherto healthy

Digitized by Google

are entitled to be protected from those whose health and whose prospects of life are already to some extent compromised. My answer is, that I believe that the attempt on the part of phthisical persons to avoid notification would in itself do a great amount of harm, not only to the individuals already suffering, but to those with whom they are in hourly and daily association. The English law as to the compulsory notification of infectious diseases was never intended to bring under a system of public sanitary supervision even a single individual who during a long series of years would have to follow his or her usual avocation. This supervision might in a majority of cases be carried out with every discretion and every effort to avoid publicity; but if it were carried out under our present system of sanitary organisation, and under our present law, it could not but run the risk of leading to hardship beyond that which the public have a right to expect others to suffer on their behalf, and indirectly this would in the end defeat the primary object held in view.

I am glad to know that I by no means stand alone in entertaining this view. A Special Commission was appointed some time since by the Académie de Médecine in Paris to study the question of the prophylaxis of tuberculosis. This Commission was composed of a number of the most eminent physicians in France. They submitted their report in May of this year, and the Académie adopted it, together with a series of resolutions. The report lays special stress on the danger which the phthisical patient involves to the public, especially by reason of the infective sputa, and it makes a series of recommendations, some of which affect the phthisical power. The transport that the disease that phthisical person. The proposal that the disease shall be made the subject of compulsory notification is then discussed at length, and two principal reasons, in addition to others, are given against the proposal. The first sets out the consideration that the moral effect of divulging by means of an official declaration that which is in effect a medical secret would be harmful It recalls the fact that phthisis is not a disease that can be classed with infections such as diphtheria or small-pox; but that, in the estimation of the public at least, it has an hereditary as well as an infectious aspect, and as such it is a disease the incidence of which should not be noised about beyond the family circle. In brief, it is held that the public would not accept such a legal enactment without protest and resistance ("sans protester et sans se défendre"). The grounds on which this conclusion was arrived at may, in some respects, have more force in France than in this country.

The second reason is deemed to be the more important. It is that, in a family unwilling to adopt the needed precautions, it would be impracticable to impose any restriction, applying as they would to a disease that would necessitate an almost continuous intervention on the part of the sanitary officers for months, and even for years. One alternative alone is deemed sufficient to meet such cases, namely, consignment of the sick person to a hospital, and this, it is explained, is the actual practice followed in Norway.

The final conclusion of the French Commission as regards the compulsory notification of this disease is: "It must not be dreamt of—at least for the present" ("Il n'y faut donc pas songer, au moins actuellement").

But let it not be imagined that I am callous to the fact that in England and Wales alone considerably over 40,000 deaths are still registered every year as due to phthisis, the form of tuberculous disease which is so especially identified with an aerially-conveyed infection, and with which dried sputs may reasonably be held to have important concern. For us in this country it is important to remember that all our sanitary legislation has been based on antecedent education, whether this has been acquired as the result of bitter experience or by repeated teaching and example. And it has been wisely held that whilst our legislative and administrative measures should always be just so far in advance of public opinion as to draw that opinion further along the path of progress, it is most necessary to avoid so great or so hurried an advance as may tend to alienate the public and thus to lead to resentment, and even resistance.

During the last few years scientific research has indicated how the phthisical patient himself becomes a danger, and the physician engaged in the practice of curative medicine has joined those who, carrying on the work of preventive medicine, have for many years waged so successful a contest against pulmonary tuberculosis. To the former the so-called "crusade" against tuberculosis is new; but happily he joins it just at the moment when his influence in promoting the necessary education for the further control of this disease is

likely to be of overwhelming importance. His advice is sought by a phthisical person, and counsel which is sought is generally followed. There are also many who would be careless, even indifferent, to precautions which they might be urged to adopt in the interest of the public but who have their their their statements. interests of the public, but who, when told by their physician that unless they adopt one and another simple precaution they will necessarily diffuse a fatal infection within their own homes and to their immediate relations, would readily do all that they were bidden by way of And when once the adoption of precautions precaution. had become the habit at home they would equally be carried out elsewhere. It is, therefore, to the advice given by those who practise the curative branches of medical science, whether in hospitals or in private, that we must so largely look for the first steps towards progress in this matter. The action of the physician with regard to the individual patient, coupled with that of the medical officer of health in diffusing knowledge as to the causes of tuberculosis among the public generally, will, in my opinion, be more akin to the measures which have been adopted in New York than that of making phthisis a notifiable disease under the English law. Already a number of excellent codes of advice and of rules as to this have been laid down by the medical staffs of certain hospitals for the treatment of phthisis, by certain medical officers of health who have induced the sanitary authorities to distribute them in the form of leaflets, and by certain associations.

Whilst discussing the question of the notification of phthisis, I would recall the fact that before any infectious diseases were made notifiable under statute, certain sanitary authorities had arranged to pay fees for a voluntary notification of some of the infectious maladies, and that the results of this action went in large measure to educate the public to the need for embodying the necessary requirements in a general statute, and this precedent seems to me to be worthy of imitation for the purposes of phthisis.

I can also see great advantage in the construction, for public health purposes, of isolation hospitals for phthisical patients. The educational effect of even a temporary residence in such an institution, where the adoption of precautions against the diffusion of the tuberculous infection would form a rule of life, would, in my opinion, be very great. Such institutions would also have other advantages. They would provide the conditions favourable to the complete cure of persons suffering from incipient phthisis, and who, if left to themselves, would ultimately succumb, leaving those dependent on them to be a burden on the public rates; and they would further serve to provide, in separate buildings, for those who, whilst suffering from the more advanced forms of the disease, could not fail to act as diffusers of the infection around them and to add to the misery of their own homes.

Three administrative measures, therefore, deserve attention. First, the education of the public by physicians, health authorities and others in the causes of tuberculosis and in the means for preventing its spread. Secondly, the provision of means for the temporary isolation of persons suffering from phthisis in its various stages. And lastly, certain corporate public health authorities might find themselves able to carry out as an experiment a system for the voluntary notification of phthisis, and even of all forms of tuberculosis in their districts.

Since these lectures were delivered great prominence has been given to the question of the prevention and control of tuberculosis by the important gathering which was summoned by His Royal Highness the Prince of Wales, to meet at Marlborough House on December 20th, 1898, in connection with the formation of "The National Association for the Prevention of Consumption and Other Forms of Tuberculosis," and I was struck with the fact that among the speakers there was absolutely unanimity on two points, namely: (1) That the greatest danger which man incurs of receiving the tuberculous infection lies in the use of milk from tuberculous cows; and (2) that the best chance of destroying

the tuberculous infection when once received into the lungs is by treatment in the "open air."

The knowledge we now possess as to the striking effects of the "open-air treatment" on pulmonary tuberculosis when it already exists, needs to be applied for the prevention of that disease; for the cost of erecting sanatoria in sufficient numbers for the cure of tuberculous toria in sufficient numbers for the cure of tuberculous consumption so long as we allow a principal cause of tuberculosis to remain in operation would, in itself, largely defeat the object which is aimed at. It is, therefore absolutely necessary that the public should be aroused to the danger of confining milch cows, whose place in Nature lies in the open air of our pastures, in the small amount of air-space now allotted to many thousands of those animals in cowsheds and byres, some of which they never leave for the whole period during which they are supplying milk for human eriod during which they are supplying milk for human beings.

SOME INTERESTING CASES OF DISEASE OF THE OVARY WITH AMENORRHŒA.

By JAMES OLIVER, M.D., F.R.S. (Edin.), F.L.S., Physician to the Hospital for Women, London.

CASE I .- Dermoid of the Left Ovary with Amenorrhæa in a Patient with Acromegaly—Operation—Recovery.—Mrs. P.—, æt. 34, married four years, has had one child. This child was born on January 10th, 1897, and was suckled until February, 1898. She consulted me on September 19th, 1898, and the following facts were then elicited. Since the birth of the child there had been complete amenorrhoea. Two months before her visit to me she was suddenly seized with pain in the left iliac region, and since then she has complained more or less of pain in the lower portion of the left abdomen. There had never been any symptoms referrable to the bladder or

Physical Signs.—Palpation of the abdomen reveals

nothing unusual.

Vaginal Examination.—The cervix uteri is located well forward and towards the right wall of the pelvis. The os is slightly open. The vaginal roof to the The os is slightly open. left of the cervix is pushed down by a swelling which appears to be a thick walled cyst with a slightly nodular mass projecting from its summit (this irregular nodule was easily detected by bi-manual examination). The body of the uterus is directed somewhat backwards, and its left border is incorporated with the pelvic tumour. The temperature is 99 degs. F., and the pulse numbers 100 per minute.

History of the Acromegaly.- The hands, which are broader and generally larger than those of any male engaged in arduous manual work, began to enlarge soon after marriage. Twice since marriage patient has had the size of her rings increased. The feet are much broader and bigger than they were four years ago. The face, too, is wider and altogether heavier looking than it used to be. The tongue is very large. During the last eighteen months patient has complained of pain and numbness in the middle and ring fingers of both hands, but to a less extent in the left than in the right. In warm weather the pain and numbness have been so slight that they have scarcely attracted attention.

tumour which was a dermoid of the left ovary was imbedded in old inflammatory material, and was firmly adherent to the posterior surface of the left broad ligament and to the uterus. With much difficulty it was enucleated. The mesovarium was very broad, and had to be secured by four interlaced ligatures. The tumour contained cartilage and bone, but the irregular nodule, which was detected by bimanual examination springing from the summit of the tumour, proved to be a very cirrhotic portion of the ovary.

Remarks.—It was difficult to account for the amenorrhea in this case, as the confinement had been an easy one, and no untoward condition connected with this event had been noted. I was disposed to believe it was quite independent of the pelvic tumour, and was attributable rather to the general

condition of the patient.

CASE II.—Multicystic Disease of Both Ovaries, occurring soon after Marriage, causing Amenorrhæa and Colostrum to be obtained from the Breasts-Operation-Recovery.-Mrs. B., et. 39, and married 18 months, has had no child and no miscarry. Menstruation began at the age of 14, and the discharge, which has always been rather free, has usually flowed for seven days. She was last unwell 12 months ago, having menstruated regularly for six months after marriage. After two menstrual periods had been missed patient observed that her abdomen and breasts were increasing in size, and she naturally considered herself pregnant. The abdomen gradually increased in size until the menstrual discharge had been in abeyance eight months, but during the last four months patient thinks it has remained fairly stationary. Movements have been felt since about the fifth month. There has been throughout no sickness and practically no pain. She consulted me because she had gone nearly three months over the time when

she had expected to be confined.

Physical Signs.—The abdomen is prominent. It bulges more especially a little to the left of the umbilicus over an area with a diameter of about four inches. The upper border of this bulging is located two inches above the level of the umbilicus. Palpation detects a swelling which is irregular in outline and consistence. It arises from the pelvis and extends to three inches above the umbilicus. At the level of the anterior superior spines of the ilium it measures transversely seven inches, and the greater portion of the swelling is located in the left half of the abdomen. Over a small area an inch below and a little to the left of the umbilicus the percussion note is resonant, elsewhere the note over the tumour

Vaginal Examination.—The cervix uteri is located high, in close apposition with, and somewhat to the right of, the pubic bone. It is rather soft, but the os is not open. Douglas's pouch is occupied by a solid or very tense cystic swelling, which is continuous with the right half of the abdominal swelling. The body of the uterus cannot be differentiated. Colostrum is obtainable from both breasts. sounds are heard on auscultating over the tumour.

Operation.—The abdomen was opened mesially It contained a small quantity of free fluid. Both ovaries contained a large number of cysts, varying in size from that of a walnut to an orange. The right one was partially concealed by its corresponding broad ligament. The left one was peculiarly concealed by small intestine. Several of the cysts in each had to be tapped in situ before the delivery of either could be attempted.

CABE III. Unilocular Cyst of the Right Ovary with a Solid Fibro-myoma in the Cyst Wall, occurring in a Virgin and associated with a Six Months' Amenorrhoea— Operation.—The abdominal cavity was opened Operation—Recovery.—Miss S., æt. 36, began to men-mesially by an incision measuring five inches. The structe at the age of 12. The menstrual discharge, which had usually flowed for six days, had recurred regularly until six months ago, since which time there has been complete amenorrhea. For two months she has remarked that her abdomen has been increasing in size, and since she was last unwell she

has complained occasionally of sickness

Physical Signs.—The abdomen is full, but somewhat flat. It is occupied centrally by a swelling which arises from the pelvis and extends to one inch above the umbilicus. Projecting from this swelling on the left side about the level of the anterior superior spine of the ilium is a small tumour of about the size of a small orange. The small tumour can be moved to a slight extent on the surface of the larger one. Fluctuation is obtained.

Vaginal Examination.—The cervix uteri is located fairly centrally. The vaginal roof in front and to the right of the cervix is pushed slightly down by a portion of the abdominal swelling. The body of the

oterus cannot be differentiated.

Operation.—The abdomen was opened mesially.

The tumour was an unilocular cyst of the right ovary, with a solid fibro-myomatous tumour (encapsuled) in the cyst wall. The left overy was quite healthy.

MODERN VIEWS ON GOUT IN RELATION TO TREATMENT. (a)

By A. DE THIERRY MOUILLOT, B.A., DUB., M.A., M.D., Harrogate.

THE author alluded to certain chemical facts which he considered to have been settled by the researches of Sir William Garrod, Sir William Roberts, and Dr. Luff. He observed that gout was accompanied by the presence of uric acid in the form of quadriurate in the blood in recognisable quantity which is deposited in the tissues in the form of sodium biruate owing to the action of the serum salts, particularly sodium chloride. He then argued that the presence of an abnormal quantity of uric acid in the blood must be due to a loss of the balance between production and excretion, and that as in gout rather less than the normal amount of uric acid is eliminated in the urine, it was necessary to assume that there was a relative inadequacy on the part of the kidneys to eliminate all the uric acid formed, whether in excessive quantity or not.

Although believing that this relative inadequacy was a necessary concomitant of gouty deposit, Dr. Mouillot did not believe that the kidneys were solely at fault or that uric acid was produced, as well as excreted, by those organs. Dr. Luff's argument that if uric acid were made elsewhere it must be carried to the kidneys by the blood was doubtless a strong one, and his failure to find any uric acid even in the blood of birds was a strong point in favour of the renal origin of uric acid, but Dr. Chalmers Watson's recent investigations which show that uric acid is present in the blood of birds, were opposed to Dr. Luff's negative evidence. Minkowski's experiments on geese were strongly in favour of the hepatic origin of uric acid, which origin is also strongly supported by clinical evidence. The assumption that the kidness are sufficiently healthy to perform a synthe kidneys are sufficiently healthy to perform a synthetical process, and not healthy enough to eliminate the substance formed, is not so rational as that the failure on the part of the kidneys is in power to eliminate uric acid made elsewhere. Besides, both the supposed antecedents of uric acid, urea and glycocine, are made in the liver, and it is probable that their conjugation takes place there also.

Dr. Mouillot believed that the proximate cause of

the gouty state lies in a defective metabolism of proteids due to a functional disease of the liver or intestinal glands, and that the deposit of sodium biurate is due to deficient elimination by the kidneys, owing to a diseased condition or through their action being inhibited by an impure condition of the

Dr. Mouillot took Sir William Robert's view as to the deposit of sodium biurate being the cause of the articular symptoms and many of the non-articular symptoms.

In the differentiation of gout from rheumatism, stress was laid on the condition of the fingers, and also on the deposit so often found in the conjunctival

surface of the lower eyelid.

In speaking of the treatment, Dr. Mouillot argued from the action and success of colchicum that the objects aimed at should be to diminish the quantity of uric acid formed and stimulate the intestinal glands and liver, whilst endeavouring to remove all the uric acid formed through the excretory organs. Colchicum probably acts by its effect on the liver and intestinal glands, which increases the quantity of bile, thus removing, in the form of glycocholic acid, one of the antecedents of uric acid. Colchicum completely meets the indications in acute gout.

Chronic gout and goutiness must be treated mainly by diet and periodic visits to watering places. The main points in diet are to drink fluid freely apart from meals, and to make the meals as little complex as possible. Stimulants should never be taken except at meals on account of their effect on the liver. As to watering-places, Dr. Mouillot considered that British Spas were sufficient for every purpose, and that the medical man was as important as the

He considered that Sir William Roberts's objection to Spas, the waters of which contained sodium salts, and his preference for indifferent waters was unfounded. With respect to Harrogate it was found that the exhibition of a full course of treatment by the waters reduced the amount of uric acid, whilst increasing that of urea, eliminated. This is what is required in gout, and is a similar action to that of colchicum, the reason evidently being that the sulphur saline waters remove by the bowels some of the antecedents of uric acid, whilst their stimulating effect on tissue change, increased the principal product of metabolic activity—urea. The charge made by Sir William Roberts that saline waters can only do good by precipitation of the sodium biurate out of the blood into the joints is unfounded as far as Harrogate is concerned, for acute gout developing under treatment there is rare.

Dr. Mouillot concluded by reading notes of the only two cases of acute gout which had occurred in his practice whilst the waters were being taken. One case was remarkable in that the patient had never tasted meat in his life, and lived entirely on milk and vegetables.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD FRIDAY, MARCH 24TH, 1899.

The President, Mr. Langton, F.R.C.S., in the Chair.

ABDOMINAL ANEURYSM TREATED BY INSERTION OF SILVER WIRE.

THE PRESIDENT read notes of a case of aneurysm of the abdominal aorta successfully treated by the introduction of silver wire. The patient was a woman who had had an abdominal swelling since the birth of a child three months before. She had wasted having lost two stones in weight

⁽a) Abstract of paper read at the Harveian Society of London, March 16th, 1899.

' in twelve months. On admission there was a pulsating tumour in the epigastrium three and a half inches in diameter, which was moveable laterally but not vertically, and there was a loud systolic murmur over it. In April, 1898, as the swelling was increasing, and the pain very severe, an exploratory laparotomy was performed, and the tumour was found to be aneurysm of the upper part of the abdominal aorta. A trocar was introduced into the sac and not much blood issued from the cannula when the trocar was withdrawn. As there was some difficulty in introducing salmon gut into the sac, silver wire was used and five feet thereof was introduced without difficulty. The puncture was secured with a silk ligature. There was some vomiting, and a good deal of restlessness after the operation. A month later the tumour was carefully examined, and it was found that consolidation was occurring As a result of the manipulation, however, there was return of the vomiting, severe rigor, and collapse. These alarming symptoms yielded to treatment, and the after progress was uneventful. She had been seen from time to time, and there was at the present time a hard mass in the middle line much smaller than before the operation, and the thrill and bruit had disappeared. Her health was excellent. The author observed that there were only a few successful cases of this kind on record.

OPERATIONS FOR PYLORIC OBSTRUCTION.

Mr. RUTHERFORD Morison related an interesting series of cases illustrating the results of operations for pyloric obstruction. The patients were shown, for pyloric obstruction. The patients were shown, and sections from the growths removed, were exhibited by the lantern. 1. A case of recovery after pyloroplasty for stricture of the pylorus. The patient was a woman who was operated on in October, 1894, the case being published in the Lancet in April, 1895. At the time of operation she was fed entirely by the rectum. She was now in perfect health and could eat anything. He made an incision an inch and a quarter from the pylorus, passed a guide through it, and then made an incision through all coats, and then sutured the incision so that the line of union was transverse to his incision. 2. A woman, et. 40, who had had severe pain after food for six months, and vomiting and emaciation for two months. There was a tumour the size of an orange which could be felt near the umbilicus, and which proved to be a scirrhous mass. Pylorectomy was performed in October, 1897. She could now eat anything, was in good health, weighed a stone and a half more than before the operation, and there was no evidence of recurrence. Mr. Morison said he had performed this operation nineteen times and all had recovered. No relapses had ever occurred. 3. A man, æt. 48, who had had severe pain after food and emaciation for some time. There was a growth of encephaloid cancer reaching nearly up to the pylorus, which was excised with the growth. He was now in good health, and had gained nineteen pounds in weight in the six months after the operation. 4. A woman, et. 41, who had had pain and vomiting for a year. There was great dilatation of the stomach, due to an adeno-carcinomatous growth, the size of a walnut, in the pylorus. She had gained two stones since the operation in September, 1898. 5. A man, æt. 38, who had rapidly emaciated and suffered from pain and vomiting for ten weeks. There was an extensive colloid carcinoma involving the pyloric half of the stomach which was removed, and the cardiac end joined to the duodenum, hy a modification of Billroth's method. A chain of glands was affected, and had to be removed. The patient was now in excellent health, and there were no signs of recurrence. 6. A man, et. 41, on whom he had performed pylorectomy for a small scirrhous mass six weeks ago. The man was now quite well, and had gained more than a stone in weight. The operation was in Mr. Morrison's opinion safer than gastro-enterostomy, and should be performed whenever the tumour was movable, size of the tumour not being an important consideration.

Mr. Charters Symonds congratulated the author on his excellent results. He had tried the method of pyloroplasty described in one instance with a satisfactory result, and he had to operate on the patient later for some other trouble, and found that no adhesions had up for the examination instructed before the patient later for some other trouble, and found that no adhesions had

occurred. In one case of pylorectomy he had found that no adhesions had occurred. In one case of pylorectomy he had found difficulty in joining the duodenum and stomach, and he had finally to employ a Murphy's button. The ultimate result was good, the patient being able to return to work. He was inclined to think more favourably of gastro-enterostomy than Mr. Morison did. He had performed the operation twenty times, and had seen nothing but good result from it. It had given great relief where removal was impossible.

Mr. W. G. Spencer also congratulated Mr. Morison on his splendid results, and observed that there seemed to have been unusually little involvement of lymphatic glands in his cases, considering the size of the tumours. He thought the end-to-end approximation of stomach and duodenum was better than the method employed in Germany of closing the cut end of both organs, and then making a lateral opening between the two. Mr. Spencer had performed pyloroplasty successfully, but he preferred to pass his sutures only through the peritoneal and muscular coats, using a Lembert's suture of fine silk, and an ordinary round sewing-needle. He thought that gastro-enterostomy was of great service in cases where excision was impracticable.

Dr. RADCLIFFE CROCKER described a case and showed drawings of a case of

LYMPHANGIOMA TUBEROSUM MULTIPLEX.

The patient was a female, who had first noticed the lesions at the age of eighteen. There were numerous small smooth papular elevations on the skin over the upper part of the chest. They were most abundant under the clavicles, and without any definite arrangement, although there was a tendency for them to follow lines from the shoulders to the sternum. They were confined to the upper part of the chest with the exception of a few outlying papules on the neck and in the axillæ. Some of them were yellowish or brown, but some of them were the same colour as the surrounding skin. There was milium between the spots and on some of them. Microscopically they had a cystic structure with some glandular elements. The patient was in robust health, and experienced no inconvenience from the spots beyond their preventing her from wearing low dresses. The condition was a rare one, only ten cases having hitherto been recorded.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, FEBRUARY 10TH, 1899.

The President, Dr. F. W. KIDD, in the Chair.

DISCUSSION ON THE BOTUNDA HOSPITAL OBSTETRICAL REPORT.

AFTER some remarks by Dr. More Madden, Dr. W. J. Smyly thought it was a very great gain to have done away with the plug in the treatment of abortion. In the treatment of placenta prævia the same method was used at present as during his tenure of office at the Rotunda Hospital, when there was not one death as the result of hæmorrhage from placenta prævia, though two cases had ended fatally. One of these patients had been delivered by the old method of version and immediate delivery, and had died after a short time from hæmorrhage and rupture of the cervix, and the other had died on the tenth day of pulmonary embolism. Coming to accidental hæmorrhage, he considered that the best treatment was still practised—namely, that if the patient had not strong labour pains it was a mistake to rupture the membranes, and if there was external hæmorrhage the uterus should be plugged. In London, students taught at the Rotunda had been rejected at examinations for not saying that they would rupture the membranes in such cases. Even the nurses who go up for the examination of the Obstetrical Society were instructed beforehand to say, if asked what they would rupture the membranes, which, he thought, would be most improper.

Dr. Macan pointed out that the mortality of the internal department was, contrary to what they would expect, twice that of the external department. He deprecated the time limit of four hours as an indication for the application of the forceps as given in the Report. Indications on the part of the mother or child were admissible, but the time indication was ridiculous. He noticed a case of eclampsia which was stated to be absolutely free from albuminuria, and therefore not capable of being explained by the ordinary theories. There was a case of brow presentation above the brim where the forceps had been applied. He thought that the forceps were contra-indicated in such a case.

Dr. Kind referred to the fact that in about 50 per cent. of the cases of rise of temperature after delivery no explanation of the cause of this rise could be given.

Dr. Pureroy, Master of the Rotunda, in reply, said that, with regard to the use of ergot in post-partum hæmorrhage, it was needless to say that they only used it when the placenta was absent. They employed Squibb's preparation of ergot, and he commended its use as it had given satisfactory results. One possible explanation of the fact that the mortality was greater in the internal than in the external department was, of course, that the bad cases in the external maternity were admitted into the hospital. The four-hour limit was only one, and the least important, indication in the use of the forceps. The other indications on the part of the mother and the child were also taken into account. He agreed that it was unsatisfactory not to be able to assign a cause to the cases of rise of temperature which Dr. Kidd had referred to, but the fact remained that they were unable to give a tangible cause for the elevation, as a large number were not interfered with, even to the extent of a vaginal examination.

The Section then adjourned.

HARVEIAN SOCIETY OF LONDON.
MEETING HELD THURSDAY, MARCH 16TH, 1899.

HENRY JULER, F.R.C.S., President, in the Chair.

DR. MOUILLOT, of Harrogate, read a paper, entitled MODERN VIEWS ON GOUT IN RELATION TO TREATMENT, a full abstract of which will be found in another column.

In the discussion following, Dr. BEZLY THORNE said that it had been a pleasure to him to listen to an exposition of views so largely in accordance with his own. He particularly wished to emphasise his conviction that granular kidney is a cause neither of gout, high tension, nor heart affection. All three, he believed to be consequential expressions of a general condition of blood-impurity in the maintenance of which a chronic gastro-duodenal catarrh, bringing in its train pan-oreatico-hepatic obstruction and gastro-intestinal and gastro-intestinal fermentative changes, is the fundamental cause. The gastro-duodenal factor might possibly have much to do with the part which the liver plays in the uric acid diathesis. Dr. Thorne thought that he could not better indicate his views as to the relation which diet bears to the toxemia of which uric acid is one of the most easily recognised, but probably by no means the most active, agents, than by giving his own personal experience. Starting with the worst possible inheritance as to uric acid, some sixteen years ago he became subject to tender nodular enlargements on the bones, mainly of those of the hands and feet, as well of the articular ends of the clavicles. Soon he had to abandon the use of the phalanges of the left hand as pleximeters in percussion on account of the periostitis which it induced. Migraines which had occurred at rare intervals, become more and more frequent until they disabled him two or three times a week, and at length a permanent tenderness of the left lateral sinus became established, and for two years compelled him to step with the greatest caution lest an access of pain should be brought on. All this time there were evidences of biliary obstruction or inhibition, and the daily evacuation of considerable quantities of uric acid. The failure of his health culminated about thirteen years ago, in two accesses of what would now be

probably called appendicitis, an affection which he believed to be intimately associated with that condition of the digestive tract which is characteristic of the uric acid diathesis. While laid aside with the second attack, he became convinced that a gastro-duodenal condition, identical with that which had been denominated "mucous disease" and "cœliac disease" of young children, was the causative factor of his own ill-health, and he resolved to effect a revolution in diet and treatment. What that involved they would understand when he stated that from the beginning he had abandoned all wine and sweets, taken almost daily a dose of saline aperient, and one of calomel once or twice a week, and that for more than a year not one shred of butcher's meat had passed his lips. As soon as the subsidence of the acute symptoms allowed, he adopted a diabetic dietary, foreswore saline aperients, and took to drinking about two pints of water, generally warm, at such times as would not interfere with gastric digestion, instead of vainly trying to quench thirst with draughts of efferves-cing mineral waters, and in about three weeks returned to a state of health which he had not known for years, and, moreover, had maintained in increasing degrees ever since. It was, he said, necessary to add that he had treated the condition of the digestive organs with preparations of bismuth and of soda, and that he had found it necessary to maintain that treatment during the greater part of the seven succeeding years in order to prevent relapse. He had now, for many years, treated his patients on the same lines and with varying success, and, for that reason, he was inclined to regard the embargo on sodium salts as a bugbear based on laboratory experiments rather than on clinical observation. One of the secrets of success he believed to be the enforcement of simplicity of diet, because the stomach of a gouty patient could deal effectually with a meal of animal food and succulent vegetables, but would utterly break down in the effort to digest half a dozen kinds of food at the same time. Monotony of diet also had its drawbacks, and occasionally he found it necessary to place an inveterately gouty patient on an exclusively milk or vegetable diet for a few days or a week in order to give the stomach a change of digestive function.

Dr. A. P. Luff urged the importance of avoiding the use of salicylic acid or sodium salicylate in the treatment of gout, since it was not only useless, but in many cases he had found it do positive harm. He entirely supported Dr. Mouillot's statement that many gouty people drank too little, and especially he had found this to be the case with female gouty patients, in whom the total amount of daily fluid consumed would frequently average not more than 18 to 20 ounces. He thought that his investigations on the influence of alkalies on the solubility of gouty deposits had been misunderstood by many medical men. He had never advocated the abandonment of alkalies in the treatment of gout. What he had shown was that alkalies and their congeners were useless when administered with the object of dissolving gouty deposits, but he (Dr. Luff) frequently employed alkalies in the treatment of gouty dyspepsia and of gouty affections of the liver.

Mr. Wm. Armstrong (Buxton), while agreeing with Dr. Mouillot that gout was more frequently met with than rheumatism, thought that there was just now rather a tendency to consider all articular and muscular pains gouty, and to underestimate the rheumatic element which was often of considerable importance from the point of view both of therapeutics and of dietetics. Dr. Luff's valuable work had shown that in cases of persistent gout and goutiness there was almost constant failure to excrete the normal amount of uric acid; and he (Mr. Armstrong) had been greatly aided in the diagnosis of doubtful cases by the estimation of the twenty-four hours urine by the Gowland-Hopkins method. With regard to dietary—as a general rule a certain amount of butcher's meat was necessary. In a considerable number of cases on a non-meat diet he had observed that although the actual amount of uric acid formed got less, the rate of excretion diminished to a still greater degree. Beef and mutton certainly stimulated the process of excretion. In nearly a hundred cases dieted exclusively on minced meat and hot water there was at

first an enormous increase in the quantity of uric acid excreted, which, no doubt, the advocates of a non-meat dietary would say was conveyed into the system by the beef, but as the gouty troubles improved the excretion gradually fell to normal, although the food was unchanged. In giving red meat to the gouty it was necessary to cut down as far as possible the consumption of carbo-hydrates and of milk, and also to insist upon the drinking of hot water one hour before each meal. Fresh vegetables were of the greatest value, but they should be well cooked, and freed from crude, indigestible matter. A separate vegetable course at dinner was most useful. Certain gouty cases could be treated with an equal amount of success, either on the lines suggested, or by the dietary advocated by Dr. Alex. Haig, consisting mainly of carbohydrates, milk, and fruit, but it was of the first importance that the two classes of food should not be mixed as in that direction lay disaster for the gouty. Modern researches concerning gout seemed to resolve its treatment into two portions. (1) The prevention of the formation of the antecedents of uric acid by attention to the condition of both the gastric and duodenal digestions, and to the action of the liver, that much-abused organ, so frequently the victim rather than the culprit. (2) The stimulation of excretion by attention to the functions, of the kidneys, skin, bowels, and nervous system, to a lowered condition of the last-named

so much of the modern irregular gout is due.

Dr. MOUILLOT, in reply, said that he was much interested in Dr. Bezly Thorne's experience. It bore out his view that the initial difficulty in gout was a digestive one, and that the gouty were unable to digest the various classes of food at the same meal. The rigidity of the diet rules must be in proportion to the severity of the symptoms as a sacrifice which it might be worth while making in a severe case might not be so in a mild one. He said his view was that the true cause of gout was digestive, and that the uratic deposits which were responsible for most of the symptoms were due to sub-sequent failure of the kidneys, either as a coincidence or caused by the toxic poisoning due to the uric acid, or per-haps other poison. Dr. Mouillot was quite sure that Mr. Armstrong's practice of calling in the aid of the skin to assist the diuretic action of the Buxton waters was sound, and would limit the number of cases of gouty attacks whilst taking the waters. Dr. Mouillot confessed himself unable to judge of the accuracy of Dr. Chalmers Watson's work which Dr. Luff had so ably criticised, nor, if accurate, did it prove that uric acid was not made in the kidney, but merely removed a difficulty out of the way of those who held that view.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY MEETING HELD THURSDAY, MARCH 2ND, 1899.

DR. ALFRED ROBINSON, President, in the Chair.

Dr. Keeling showed the specimens removed, and gave details in the following cases:—1. "Cystic Myoma of the Uterus," successfully removed by abdominal of the Uterus," successfully removed by abdominal section in an unmarried woman, the uterine wound being treated intra-peritoneally. 2. "Dermoid Cyst and Ovary," patient single. Recovery good. 3. "Broad Ligament Cyst," removed from married woman, æt. 30, sterile, married ten years. Recovery excellent. 4. "Menstrual Fluid removed in a case of Imperforate Hymen." The patient, otherwise a healthy, well-grown girl, st. 17, had never menstruated. 5. "Cancerous Uterus, removed by Vaginal Hysterectomy from a Married Multipara, st. 42." Recovery had been excellent, with the serious exception that an urinary fistula had resulted, probably from the bladder having been caught by one of the forceps used in securing the broad

A discussion followed on the operative treatment of fibro-myomata and cancer of the uterus, in which Dr. Martin, Mr. Richard Favell, Dr. Sinclair White, Mr. Pye-Smith, Dr. Andrew Walker, and Mr. Sydney Barber took part.

Dr. ARTHUR HALL showed the following pathological specimens:-(1) "Heart with stenosis of the pulmonary

artery, imperfect ventricular septum, and patent ductus The specimen was taken from a boy, æt. 11, arteriosus. who died of pneumonia, The cyanosis was not extreme, except during the last few days of life. (2) "Liver with gall-stones in the gall-bladder, an impacted stone in the ductus choledochus, several stones in the intra-hepatic bile ducts, which were largely dilated." The left lobe was breaking down with multiple abscesses secondary to well-marked cholangitis. At the left extremity of the liver there was a large subphrenic abscess, which seemed to be secondary to the suppuration, in the left lobe of the liver. (3) "Carcinoma of the bodies of the ninth cervical and upper three dorsal vertebræ, part of a widely distributed C cer," the primary seat of which was not discovered. The bodies of the vertebræ had given way and produced transverse myelitis, which was the immediate cause of death. (4) "Typhoid ulcers," preserved by Kaiserling's method with formalin and glycerine.

Dr. CAIRNS showed the specimen and gave the details of a case of "Ectopic Gestation," which was diagnosed by Dr. Andrew Walker and himself, and successfully operated on by Dr. Sinclair White.

Dr. George Wilkinson gave an account of a case of

Dr. George Wilkinson gave an account of a case or "Subphrenic Abscess," operated upon by him at the Royal Hospital. The patient was a man, et. 47, who was admitted acutely ill, with a prominent, tense, fluctuating swelling in the epigastric region. Hepatic abscess was diagnosed, the swelling was incised, and two pints of pus and hydatid fluid evacuated. The patient complained of much pain in the left side when being lifted on to the operating table. Next day there being lifted on to the operating table. Next day there were signs of a subphrenic collection of fluid on the left side. This was evacuated and drained after resection of a portion of the 7th rib in the anterior axillary line, and suture of the costal pleura and the diaphragm. Drainage was continued for two months, after which the cavities healed, and patient was discharged.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT SHEFFIELD, MARCH 17TH, 1899.

Dr. Donald, President, in the Chair.

SPECIMENS.

Dr. Keeling showed the following specimens:—(1) Large cystic myoma of the uterus, (2) dermoid cysts of both ovaries, (3) tubo-ovarian cyst

(1.) Dr. FAVELL related a case of cancer of the cervix associated with three months' pregnancy. The uterus was successfully removed by vaginal hysterectomy.

(2.) The President (Dr. Donald) reported a case in which he had performed vaginal hysterectomy for post-partum hemorrhage The patient, a primipara, was observed, before labour, to have an extremely thin uterine wall. Labour came on spontaneously, accompanied, however, by extreme inertia, and was completed by forceps. Profuse and intractable post-partum hæmorrhage ensued, resisting all the usual methods of treatment, including plugging with gauze. The patient was apparently moribund, but it was decided to perform vaginal hysterectomy as a forlorn hope. The operation was easy and only occupied ten minutes, clamps being used. The patient temporarily improved, but died an hour later. Dr. Donald was of opinion that if the operation had been done a few minutes earlier the patient's life would probably have been saved.

Dr. Walls introduced for discussion the subject of

"the treatment of some cases of Accidental Hæmor-rhage," adjourned from the last meeting. In these cases Dr. Walls advised that the membranes should not be ruptured until the cervix was fully dilated or dilatable. There was no objection to plugging the vagina, especially if combined with a hydrostatic dilator, such as de Ribe's bag. After delivery by forceps or version the great danger was from the almost invariable post-partum hæmorrhage. If the usual measures, including plugging with iodoform gauze failed, he advised vaginal extirpation of the uterus as a last resort, believing that in this way certain lives would be saved.

Dr. GLYNN WHITTLE, in an experience of 10,000 labours, had met with severe accidental hæmorrhage in sixteen cases. Of these all the infants died with one exception, but fifteen of the mothers recovered. He had never used hydrostatic dilators, but preferred to firmly plug the cervix and vagina, followed by manual dilatation of the cervix and delivery by forceps or version. The post-partum hæmorrhage was, in his experience, always controlled by a hot uterine douche. He could not support the suggestion to perform Porro's operation or vaginal hysterectomy in such cases, believing that a woman who could survive hysterectomy would certainly be saved by a vigorous application of the above principles of treatment.

Dr. Martin considered that cases of very severe accidental hæmorrhage were of great rarity, but in such cases he agreed with Dr. Walls that if other methods fail to check the bleeding hysterectomy was quite

justifiable.

Dr. Leas suggested that in cases of severe internal bleeding with the os undilated and extreme uterine inertia accouchement force by the aid of free incisions in the cervix should be carried out.

Remarks were also made by Drs. BRIGGS, KEELING, and the PRESIDENT, and Dr. Walls replied

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, March 25th, 1899. OSTEOMALACIA IN MAN.

AT the meeting of the Academy of Medicine, M. Berger communicated details of the case of a young man who entered his wards for double genu valgum. Osteotomy above the left condyle was practised, the knee straightened out, and some time afterwards the femur was found to be consolidated. Towards this period, however, the patient complained of violent spontaneous pain in all the extremities, except in the operated limb. These pains were first considered to be those of rheumatism. It was only three months subsequently that abnormal mobility was remarked in the bones of the two lower extremities, which became the seat of considerable deformity. Analogous pains were felt in the arms, and these became deformed in their turn, and finally the thorax and the head were attacked in a similar manner. The vertebral column alone resisted the process of disintegration. The patient was besides suffering from interstitial nephritis, which by its rapid progress threatened his life. All treatment failed to arrest the progress of the primary disease.

Volvulus of the Sigmoid Flexure.

M. Routier spoke on a case of volvulus of the sigmoid flexure. A woman presenting all the signs of intestinal occlusion entered the hospital in July last. For a year previously she suffered more or less from violent attacks of colic, and two or three days before applying to the hospital, without any apparent cause, in the middle of the night she felt a sudden pain over the whole abdomen, and since that moment no matter nor gas had been ejected; some vomiting supervened, but not very abundant. When examined the predominating symptom was considerable tympanitis; the thermometer marked 96 degs., and the pulse was 100. After seeking in vain for the cause of the occlusion the speaker performed laparotomy. As soon as he opened the abdomen he fell on a loop of the large intestine greatly distended, and which he recognised as the sigmoid flexure. In pushing

further his exploration he discovered that the strangulated loop was retained by a thin ring which tightened it at its base on a level with the sacro-vertebral angle. He found himself in presence of a volvulus twisted from left to right. The obstacle was removed without difficulty, and the patient left the hospital cured, a month afterwards.

TREATMENT OF EPITHELIOMA.

MM. Cerny and Trunecek have published at great length in the Semains Médicale their treatment of epithelioma by daily applications of a solution of arsenic composed as follows:—

Arsenious acid, xx grs.; Proof spirit Water } 3iiss.

The result of these applications was a successive transformation of the cancerous tissue in sloughs which became detached, and finally left an ordinary granulating sore, which healed under the influence of antiseptic treatment. No prejudice was caused to patients by the application of the arsenic when care was taken to avoid touching the healthy skin. The pain caused by the action of the caustic was never so great as to oblige the patient to abandon the treatment. The curability of cancer by this method depended, however, on the degree of evolution of the neoplasm and on the seat of the lesion. As regards the first condition, it was necessary that the ganglions should not be indurated, and as to the second. the application of the toxic should be realisable Such were cases of primary cancer of the teguments, the nose, the lips, the mouth, and certain limited lesions of the larynx. As to the duration of the treatment, it was impossible to fix any period with precision | Very small ulcerations only required three or four weeks to heal, while in other cases several months were necessary. However, it was sufficient to see the patient once or twice a week as he could apply the caustic himself. As to the action of the arsenical solution, the cancerous cells were first dehydrated by the alcohol, then their protoplasm became coagulated under the influence of the arsenic, degenerescence of the cells of the connective tissue followed, provoking a serious exudation which determined in its turn certain alterations in the modified cancerous cells; finally, a distinct inflammatory line of demarcation was produced between the diseased and the healthy parts, after which the neoplasm became eliminated as a foreign body.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, March 24th, 1899. Cæsarean Section.

In the Therapeut. Monatsch., 11/98, Dr. Everke, Bochum, has an article on the subject. The author's opportunities for observation comprise thirty-five cases, two of which operations were in mortua. Twenty-five of the cases were examples of the conservative operations ix were Porro's operation with intraperitoneal treatment of the pedicle, two total extirpations. As regards results to the mother, some of the cases have to be excluded before a calculation could be made. There were two operations after the death of the mother, two deaths from eclampsia one from pre-existing exudative pleuritis, and one case in which the operation was performed to

save the child in a woman suffering from septic peritonitis. Of the remaining twenty-eight cases, four died of sepsis, one from hæmorrhage. The remaining twentythree cases did well during childbed, only a few having slight febrile symptoms. Nearly all the mothers were able to suckle the child. Out of the whole thirty-five cases, thirty living children were born.

As regards technique, the author thinks that on the basis of his own extended experience, he can recommend the following mode of procedure. It is best to wait until regular pains have set in. In place of elastic ligature it is better for two assistants to compress the broad ligaments manually. Anterior or posterior longitudinal opening into the uterus is preferable to the transverse one, as the latter entails imperfect nourishment of the wounded part and poor healing. The most important step in the operation is the careful suturing of the uterine wound. In the conservative operation the author always avoids the decidua with the deep sutures, and puts in superficial sutures of silk. In order to avoid gaping of the wound at the decidual part, and danger of infection from the uterine cavity, and also the occurrence of gangrene, too many and too deep sutures should not be applied from the peritoneal side, but in order to ensure a deep firm cicatrix he ties three to six threads from the cavity of the uterus. These sutures take in the decidus or at most the inner layer of muscle, and are easily placed in position.

He is now inclined to demand that no perforation of a living foetal head should ever be performed, at least not in a properly appointed hospital, as by means of timely Consarian section there is almost an equal certainty of saving both lives, as even in early operation in excessive contraction of the pelvis, the prognosis for the mother is equally good, i.e., in a good hospital, whether the labour is terminated by perforation or Consarian section. The prognosis becomes more unfavourable with the length of labour. Bruising and necrosis of the soft parts, soiling by examinations predispose to infection, and if a case does badly after these, the method of operation is not at fault, but the blame should rest on what has preceded it.

NEURITIS GRAVIDARUM AND NEURITIS PUERPERALIS.

A paper on this subject in Graefe's Sammlung, by Carl Marhold, brings some scattered fragmentary views into something like order. In neuritis the author includes those affections of nerves that have come on in connection with a normal or pathological gravidity, or in connection with a confinement, in a woman otherwise healthy.

The neuritis of gravidity is, according to the author, a rare condition. If it occurs during a normal pregnancy, it can only be explained on the assumption of the production of toxins setting up degenerative processes in the nervous system. The comparatively frequent combination of hyperemesis and neuritis in pregnancy is in favour of this view. The neuritides of the lower extremity, especially sciatica are possibly caused by compression of the pelvic nerves, but with a normal configuration of the pelvis the author thinks this explanation an improbable one

The distinguishing mark of neuritis of pregnancy is that there is no special preference for any particular nerve region, and the form is generally the purely motor one, The disease usually commences in the early

months of pregnancy, and disappears at delivery or shortly after. He characterises the paresthesia that affect the fingers, hands, and toes as the mildest form of the affection.

Puerperal neuritis may be a continuation of one arising during pregnancy; it may arise through puerperal infection, or the labour itself may be the setiological factor. As regards the latter form of origin, pressure from the feetal head, by application of forceps, turning, &c., must be taken into account. The most frequent form of paralysis associated with forceps delivery is that of the nervus peroneus. All these traumatic neuritides are confined to the lower extremities. Other neuritic diseases may come on during puerpery, they may be localised or general; of some of these no satisfactory explanation is at present forthcoming, and to some extent the diagnosis is unfavourable.

At the Medical Society Hr. Buske showed a case of so-called acne cheloid in a negro. The patient was from St. Domingo, and was 34 years old. The disease began two years ago without any antecedent syphilis, the patient being otherwise in good health. At first very small nodules and pustules appeared at the nape of the neck and on the head. He sojourned for a year at the Cameroons and was there treated by Dr. Plehn, but without result. On the patient's return the tumour disintegrated and discharged a sanguineous pus. He was then admitted into the Charité where he was treated by Professor Schweninger with thyosine-amine injections, but also without result. Kaposi had described the first case in 1869 as dermatitis papillaris capillitii, the French later called it acne chéloidienne. withstanding the tendency in the disease to return he had at the expressed wish of the patient operated by Thiersch's method, and was apparently contented with the present condition of affairs, although there was already some recurrence.

He then showed a patient from whom he had removed a lead pencil from the bladder by cystotomy.

Hr. Czempin showed two

ABDOMINAL TUMOURS

removed by him by operation—(a) A smaller one removed from a female, set. 56, who was supposed to be suffering from some disease of the stomach, but in whom no organic disease could be discovered. A dermoid was suspected, but the tumour proved, to his surprise, to be a sarcoma of the mesentery.

(b) A large myofibroma of the cervix uteri, weighing 27 lbs., and from which the patient had suffered from her 22nd year to her 60th. The patient had persistently declined operation until the tumour had increased enormously in size, and her girth had increased so much by this and by a large amount of ascites that she could no longer walk. The operation passed off successfully, except that in separating the last adhesion a small piece of the bladder slipped into the way of the knife. The mishap was discovered at once, and the edges of the cut were brought carefully and accurately together. After passing through many dangers the patient had recovered. There was first atony of the intestines. The stomach, as soon as it became filled with food, sank deeply into the abdominal cavity, then decubitus occurred; but the patient, as already intimated, finally pulled through.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 24th, 1899. OBESITY.

At the "Doctoren Collegium" Kölisch read an exhaustive paper on pimelosis or lipomatosis circumversalis. He first divided the disease into two large groups—1st, overfeeding without exercise; 2nd, imperfect metamorphosis. In the first the fat represented a surplus accumulation of calorific force; in the second a diminution of calorific force, but in both the adipose surplus was the common result.

The pathogenesis of this condition, he said, had not yet been clearly explained to the satisfaction of scientists as the chemical and physiological estimates of food stuffs was not a practical basis upon which to found a principle owing to the diversity of results which have already been obtained, and which Professor Kassowitz has shown to be quite untrustworthy.

For the temporary form of obesity the calorific tests may be useful, and an average man of 65 or 70 kilos. (143 to 154 lbs.) in weight, and 170 cm. (5 5774 ft.) in length, taken as a standard. Having diagnosed such cases, the treatment may be safely presented in two meals a day. The so-called "Banting," "Epstein," and Oertel systems are simply underfeeding, which may be conducted too suddenly and do harm, but, if moderate, is effectual in healthy cases.

The obesity depending on a congenital metamorphic anomaly is the disease which ought still to receive our most serious attention. Fat will be taken on with the very minimum of calorific nutrition without any explanation whatever. Carbohydrates were long accused of producing this troublesome affection, and later the oxydation of the food stuffs, but the more recent cause is pronounced by Hirschfeld to be an existing anomaly in the metabolism of nutrition, from which the accumulation of fat can also be estimated by the calorific test. This anomaly in the production of fat is, like many other human infirmities, hereditary in its occurrence, belonging to particular races and families. It not infrequently occurs in childhood, which cannot always be explained. as some authors would have us believe that the quiescent state of the muscular and nervous systems was the real source of the fat accumulation. No doubt climate and extensive hæmorrhage are factors that provoke obesity in the absence of any ancestral disposition; but, with these exceptions, the disease may be accepted as hereditary. The same analogy seems to exist with respect to age in obesity as in diabetes: the younger the patient affected the more severe and dangerous to life it becomes, while in advanced life it is usually milder in form.

To elucidate this mystery physiologists have endeavoured to show that the animal organism has the power of maintaining the equilibrium from the nutritive mass, that is, if the vital force manufactured by the cellular affinity be not used up it is stored, and thereafter inhibits the production.

This theory appears somewhat reasonable with respect to fat as its presence can hardly be denied in the amaciated appearance of the neurasthenic where the albumenoids are inhibited, although the patient may be a polyphagic and polydipsic.

Thyroid treatment is not satisfactory, besides the danger that accompanies the use of the drug.

When the gland does act, nucleo-albumen and casein should be liberally provided. The safest method is under feeding in some form or other, and the older idea of avoiding the carbohydrate group is still to be recognised. Epstein prescribes a diet of fat and albumen.

A DIGITAL CHANCRE.

At the Medical Club, Nobel showed a patient with a deep infiltrated ulcer on the face with a maculo-papulose syphilide.

The efflorescence pointed to enlarged vessels, which is peculiar to the syphilide of the potatoe. The initial sclerosis seems to have been on the terminal phalanx of the index finger, which is not uncommon in extragenital chancres. The practical point in this case, he said, was the confusion of such cases for paronitis, whose trestment was fraught with much danger to the patient.

TUBERCULOUS ULCER.

Nobel exhibited another comparative case with an ulcer on the under lip, and vesicles around it. It had the appearance of primary syphilis, but the infiltration of the neighbouring glands was slight.

A few weeks previously the patient appeared with a similar ulcer, which left no doubt of its tuberculous origin. He suffered also from an incomplete anal fistula, as well as an hereditary blemish.

HEADACHE AND NASAL DISEASES.

Weil opened the discussion on Hajek's paper, who said that neuralgia was often caused in the head by empyema of the maxillary sinus. Weil said that fluids from nasal douches often passed into the ductus naso-frontalis and caused neuralgia. Cocainising locally was the best treatment.

Elschnig thought that many cases of orbital neuralgia were not empyemic in origin.

Teleky agreed with the latter and could not understand how empyema of one side could be reconciled with bilateral neuralgia.

Königstein thought that the nasal disease might be transferred to some other part of the head, but could not agree with empyema alone producing it.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

OPERATION IN A CASE OF ARACHNOID AND SUPPOSED PONTINE HEMORRHAGE.—Mr. PEYTON BEALE operated on a woman, æt. about 46, who had been admitted four hours previously with a small scalp wound over the occiput, and who was in a comatose condition. The patient was attendant in one of the underground female lavatories; she had been found lying on her back on the tiled floor, bleeding from a small scalp wound, and only partially sensible. On admission she was much collapsed, in a state of concussion, but both pupils were contracted to pin's points. It was thought that she might have taken a large dose of an opium preparation, so the stomach was washed out, but no indication of the drug was found. She rapidly became more and more comatose, with complete paraplegia and ansesthesia; symptoms of cerebral compression then supervened, and it was decided to trephine. At this stage the possibility of a lesion of the pons, probably hæmorrhage, was fully discussed, and was considered probable on account of the condition of the pupils. The scalp having been shaved and cleansed

Mr. Beale enlarged the scalp wound in a triradiate manner, and applied a one-inch trephine just to the left of and above the external occipital protuberance. The dura-mater was opened, and about two ounces of liquid blood immediately escaped. Hitherto no anæsthetic had been used, but as the patient now began to move somewhat a little chloroform was administered. The wound was stuffed with a piece of gauze, which was pushed for about two inches in an upward direction into the arachnoid space, and, as no bleeding vessel could be seen, and as very little blood came from the wound, the scalp was sutured, and the wound dressed. Mr. Beale remarked that in all probability there had been a fairly extensive hæmorrhage from the pia-mater over the Rolandic area, seeing that the immediate relief of the tension caused by the effused blood was followed by some voluntary movement; he thought that, at the same time, there was also an intra-pontine hæmorrhage. As no fracture of the skull could be found at the seat of operation, and as there were no symptoms of any fracture by coutre-coup, which if present would have been probably in the anterior fossa of the skull, and which would have produced local symptoms, he did not consider it advisable, considering the amount of shock that was present, to undertake any further operative procedures at that time.

The subsequent history of this patient is worth noting. On the next day the symptoms of compression had disappeared. The patient then appeared to be in a marked state of of cerebral irritation, lying in a "curled_ up" position, being very irritable when spoken to, and exhibiting complete paralysis of the left side of the body, and distinct weakness of the whole of the right side. The temperature was beginning to rise, but the pupils remained fully contracted. In this condition the woman remained for about three weeks, taking liquid food, but with difficulty, and the temperature rapidly became normal and fell to subnormal. The knee-jerks which were absent immediately after the operation became exaggerated. The patient now began to improve, and her wandering speech became more and more intelligible; she complained of great pain in the left arm and leg, movement in both of which she began to regain. The stuffing from the wound was removed on the third day after the operation, and the wound healed uninterruptedly. It was not until four weeks after the operation that the patient was able to give an intelligible account of the manner in which she received her injury. She then stated that while standing on a ledge cleaning a window in the lavatory she fell suddenly to the ground; she supposed she must have slipped.

The following is Mr. Beale's interpretation of the case:—He considered it probable that the patient had an intra-pontine apoplexy, probably on the right side of the pons, which partially accounted for the hemplegia on the opposite side, and fully accounted for the persistent pin's point pupils through pressure on the nuclei of both third nerves. The rapidly advancing coma and symptoms of compression which were evident immediately prior to the operation were, without doubt, due to the extensive hæmorrhage from the pia mater.

It is satisfactory to note that the patient, some two months after operation, has completely recovered, with the exception of complaining of pain and tingling in the left forearm and hand. REGISTERED FOR TRANSMISSION ABBOAD.

WEDNESDAY, MARCH 29, 1899.

THE LIMITS OF EXPERIMENTAL MEDICINE.

MEDICINE is essentially a science of observation and, to some extent, of experiment, but it is obvious that the limits within which experiments on the human subject are permissible are, and must be, very strict. To the enthusiastic investigator the temptation to make use of the opportunities at his disposal to elucidate certain moot points in medical science may be great, but his disinterestedness cannot be admitted to constitute a justification for experiments on human beings of a kind likely to prove injurious to the subject, even with the consent of the latter, and a fortiori without his consent. Our readers may remember the sensation created some years ago by the publication in France of certain observations by an investigator, who prudently preserved his anonymity, bearing on experiments carried out by him, having for object to demonstrate the transmissibility of cancer. His observations met with unanimous and unequivocal condemnation, for it was felt that not even the advance of science could justify recourse to experiments which constituted a gross abuse of professional confidence and a not less gross violation of common humanity. The thesis has just been dramatised in Paris in a piece which is likely to excite a movement of public opinion very detrimental to the best interests of medical science. The physician of the piece is represented as having attempted the transplantation of cancer on the person of a young woman in the last stage of phthisis, having quieted his conscience by the reflection that his patient would succumb to her lung disease before the cancerous graft could be productive of any serious results. His experiment proved successful,

but pari passu with the development of the artificially communicated cancer, the chest symptoms diminished, and the clou of the piece is the moral plight of the doctor when he discovers that he has been the means of conveying cancer to a young and otherwise interesting woman, whose recovery, but for the experiment, was assured. Of course, this is all pure speculation, and as a dramatic conception it strikes one as rather feeble. curious coincidence, however, the very day this piece was being played at the Paris theatre, a member of the German Parliament called attention to the fact that a certain professor had actually published observations from which it appeared that he had injected eight healthy persons with the serum of syphilitic subjects, with the result of communicating syphilis to four of them. Minister admitted the gravity of the charge, and promised an inquiry, adding that if the facts were as stated no consideration of persons would be allowed to stand in the way of justice being done and of steps being taken to exonerate German science from such a reproach, with the object of effectually preventing the repetition of any similar scandals. gather from an interesting article on the subject, which appeared in a recent number of La Semaine Medicale, that the incriminated professor is Dr Neisser, and that the observations referred to are comprised in Vol. XLIV. of the Archiv fur Dermatologie und Syphilis. Before undertaking these experiments, in the course of an inquiry into the possibility of immunising against syphilis, Neisser asked himself the question whether the serum of syphilitic subjects was capable of communicating the disease to healthy persons. Proceeding on the assumption that serum deprived of cellular elements is, in most infectious diseases, devoid of infective properties, he made use of serum obtained from syphilitic subjects, which he had proved to be sterile by preserving it for days, and even weeks. With this serum he injected eight girls, five by subcutaneous and three by intravenous injection. A girl belonging to the first series, who had not meanwhile developed any symptom of the disease, came to the hospital three years later suffering from cerebral syphilis. All three girls belonging to the second group developed syphilis, one a month, another between five and six months, Of these and the third a year after the inoculation. eight girls, five were prostitutes and of these five four developed syphilis. Dr. Neisser denies that the syphilitic infection was in any way the result of the injections, basing his denial on the ground that as the girls were prostitutes they might have contracted the disease before or after the inoculations. That objection, however, can hardly apply to the case in which the classical symptoms developed within a month, unless indeed he was the victim of an unfortunate coincidence. Looking at the facts, as stated, it is difficult to acquit Dr. Neisser of a large measure of responsibility in respect of the causation of syphilis in these cases. We, however, are less concerned in establishing the culpability of Dr. Neisser than in condemning the

spirit which prompted such experiments. All measures, even if novel, which may reasonably be expected to assist in bringing about the recovery of the patient without injury to his health, may legitimately be resorted to with the consent of the patient, but measures, whether by drugs or by operation, which have not for direct object the cure of the patient and which may prove inimical to his health or condition, are inadmissible under any circumstances, and must expose the perpetrator to professional ostracism and to penal rebukę.

PRESERVATIVES IN MILK.

It is high time that the question of the legality of the addition of preservatives to milk should be placed on a sound basis, and not left to the whim or caprice of the presiding magistrate, who may or may not be in a position to appreciate the importance of the subject. We are first called upon to decide whether, as a general principle, the addition of preservatives to milk is admissible, apart from the eligibility of any particular antiseptic. There are many and obvious objections to the use of antiseptics in an article so largely consumed as milk, especially when we reflect that a very large proportion of the milk sold is destined for the alimentation of the very young, whose delicate digestive apparatus is exceedingly apt to resent every departure from the normal standard. Antiseptics owe their value in this direction to the inhibitive effect which they exert on the changes of decomposition; but in virtue of this very property they must, pro tanto, retard the changes which the milk has to undergo in the human stomach before it can be assimilated. The obstacle may conceivably not be one of any great importance in adults, whose digestion is normally well able to take care of itself; but it is quite otherwise with infants of tender years, who already have all the trouble in the world to make use of this substitute for the maternal supply. Then, too, the preservatives usually employed are not added in sufficient quantity to exert any destructive effect on the organisms which may find their way into the milk, while, on the other hand, they enable those who handle milk to relax to some extent the precaution of extreme cleanliness, which would otherwise be the sole available means of protecting milk against prompt decomposition. This is a question which must not be lightly decided, because in hot weather the prohibition of preservatives must mean the inevitable loss of immense quantities of the valuable fluid, which would otherwise be utilised as food. This question, simple as it may seem, is surrounded by difficulties as soon as one sets to work to apply the test of experience. It is so difficult to eliminate the action of other possible causes of gastrointestinal irritation in infants and so difficult to show that it is this particular constituent of the milk as sold which is at fault. On the whole, and looking at the matter as one of principle, we are rather disposed to question the wisdom of forbidding

the use of milk preservatives under all and every circumstances. We then come to the particular preservative employed, and here we are, perhaps, on surer ground. A few years since salicylic acid was largely used for the purpose, and it cannot be denied that the anti-putrefactive properties of this drug are very great, but so is its physiological action, and little hesitation was shown in condemning its use on this account. To obviate the objections to salicylic acid the trade now make use of boracicacid instead. Analytical chemists in support of trade interests do not scruple to assert that this substance is quite harmless but we formally deny their competence in the matter. What can a chemist know of the toxicity of this substance indeed? But what, on the other hand, can Dr. Corfield and other experts know to the contrary? They cannot have made any direct observations, or if so, they have not been made public, and in a case just now under consideration a witness who boldly stated that boracic acid was injurious to human beings was fain to admit on cross-examination that he had never tried its effects on any person, infant or adult. The same destructive criticism the evidence of the Corfields and Cassals who affirm the injurious effects of boracic acid, and that of the Smiths and Gibbons who affirm its innocuousness. They are all expressing opinions not based on actual observation. It is generally assumed that the quantities employed are so small that an injurious effect is out of the question. Apart, however, from the fact that there is, not improbably, a cumulative action when these drugs are introduced into the body over long periods of time, the actual quantities are really not as small as we are asked to believe. In a recent case the preservative contained six pounds of carbonate of soda, six pounds of borax, and twelve pounds of sugar in from eighteen to twenty gallons of water, and a pint of this precious blend was added to each churn of milk with liberty to the retail dealer to add what he might consider a suitable dose on his own account, for, be it remembered, the use of these preservatives by the wholesale man or farmer is not necessarily or even generally made known to the retailers, who take their own measures to prevent the milk from going wrong. These manipulations, moreover, are carried out by men who have no practical or scientific knowledge of the nature or physiological action of the substances employed by them, their only object being to preserve the milk at all cost. While therefore we hesitate to condemn the use of preservatives as a matter of principle, we have little hesitation in condemning the practice, simply because it must be next to impossible to assign and enforce the limits within which their use is innocuous, and therefore hygienically permissible. We are glad that sanitary authorities are waking up to their responsibility in this important matter; but if the judges on appeal are unable to affirm their objections, it will be necessary to apply to Parliament for further and more definite powers in this direction.

DR. E. W. Symes has been appointed a Justice of the Peace for the borough of Halifax.

EARLY TREATMENT OF INSANITY.

WE have referred to this important matter in our columns from time to time on the principle that, because of our importunity and the importunity of others, the legislature may be forced to yield to representations on the subject. There are few questions that have so logical and urgent a raison détre than that of the treatment of insanity, because it practically means to some extent the diminution of registered lunacy as reported by the Commissioners. A Deputation from the British Medical and the Medico-Psychological Associations recently waited on the Lord Chancellor with a view to bringing under his notice the advantages, which would accrue by a recognition in the new Lunacy Bill of the practice which has obtained in Scotland, of allowing the treatment of incipient cases in private houses for a period not exceeding six months. As pointed out by Dr. Rayner, the advantage of the clause in the Scotch Act is that the Commissioners in Lunacy are informed of the number of cases treated, the duration of treatment and the persons undertaking the treatment. They have powers of supervision when necessary, and there is no excuse left to persons to evade the law as has frequently been done in England of Dr. Ravner, who first addressed the Lord Chancellor, remarked that he had been impressed in his experience in London at the out-patient department of St. Thomas's Hospital, with the amount of recovery possible in the early stages. He thought that every improvement that could be made in the treatment of these stages ought to be made in the hope of checking that large increase of insanity in the country, which all deplored. In every case of mental disease there is a stage between acute and certifiable insanity. This has been shown by many recoveries taking place without certification when the intermediate stage has been recognised. Blandford rather fell foul of the right hon. gentleman by his statement that the Lunacy Act of 1890 enacted that every person of unsound mind should be incarcerated by the order of a magistrate. The Lord Chancellor repudiated this view, contending that the law was that the person should not be incarcerated unless the magistrate should so order. This, however, is rather a reverse side of the shield, and the difference in meaning a matter not worth quibbling about. What Dr. Blandford and Dr. Savage wanted was, to remove the risk of patients being sent away or out of sight, in order to avoid certification and facing a magistrate. This is a danger of very serious significance. There is no doubt that a strong feeling exists against anything amounting to publicity in the treatment of the insane, as well as an objection to patients being certified and treated as registered lunatics, and for this reason and because there is no proper provision for treatment in private houses as uncertified patients, there is a disposition to evade the law and, therefore, to jeopardise the prospect of recovery in many cases. Still further, as pointed out by Dr. Savage, many will not put their relatives in asylums,

because once certified and committed, the stigma of lunacy is unmistakable, and affects, socially and otherwise, the sane as well as insane members of the family. Certification has, moreover, a serious effect in the following ways. Thus, if a person is certified as of unsound mind, it may put an end to a partnership in some important business, or it may lead to the discharge of a patient from an important position either in business or in civil or other life. This is not necessary, because insanity is quite curable in many forms, and to treat a person once insane as for ever incapable of transacting business is altogether wrong. What the Deputation really desired, and in this they represent the profession, is that the law as set, should not be altered except to the extent that persons who are certifiable, but who are suffering from quite temporary maladies, may by the permission of the law be allowed to be placed, as in Scotland under private or single care and detained as patients under these conditions. The limit of time allowed by the Scotch Act is six months, but to this the Lord Chancellor somewhat demurred, being of opinion that the limit should be shorter, subject to sanction being renewed if necessary. The Lord Chancellor expressed his sympathy with the views of the Deputation, and promised to try and give effect to their suggestions. If this is done a great hardship will be removed, and many cases of incipient insanity will be effectually aborted by prompt treatment, before a certifiable stage is reached. Anything that can be done to mitigate the growth of registered lunacy is worth doing, and such a change in the law as is here proposed bears the impress of common-sense and urgency on the face of it.

Aotes on Current Topics.

Condensed "Separated" Milk.

WITH such elaborate and drastic legislation for the protection of milk consumers as we possess, it really appears odd that foreign merchants should have been left a free hand in pushing the sale of a pseudo-condensed milk, the use of which in the alimentation of infants is attended by the gravest consequences to health and life. The manufacturers of genuine condensed milk-that is to say, a product containing all the nutritive elements of milk in their normal relative proportions, minus the water-are interested, equally with the public, in seeking protection against a fraudulent substitution which cannot but bring their own high-class articles into partial disrepute. We have long since protested that condensed skimmed or separated milk ought not to be allowed to be sold as milk at all, for if that name be conceded ignorant and careless mothers are certain to be tempted by the smaller cost of the inferior product to prefer it for the alimentation of their offspring. In receiving a Deputation last week on the subject, Mr. Long premised that it was asking too much to expect the Government to prevent the public purchasing an article which they might choose to purchase, and which they were entitled to pur-

chase if they knew what it was. condensed skimmed milk is, for certain purposes, a perfectly admissible and nutritious article of food, but it is quite unsuitable for the rear ing of infants. To feed a young infant upon such milk is to condemn it inexorably to rickets, tuberculosis, or other disease of malnutrition. We see no objection whatever to a proviso that the label shall comprise a statement in bold characters to the effect that the product is not intended for the food of infants. If, as the manufacturers pretend, they do not intend it for such a purpose, this statement will not interfere with the legitimate sale, while a too economical mother who made use thereof, in spite of this warning, would lay herself open to the charge of wilfully withholding proper nourishment from her infant. To oblige the vendors merely to state plainly on each box the exact nature of the contents, will, in any event, be a step in the right direction; but in view of the harassing restrictions placed on the sale of such a production as margarine, which, under nocircumstances, can prove harmful if properly prepared, it seems absurd to authorise the sale of skimmed milk without making perfectly clear that it is absolutely unsuitable as an article of diet for young infants.

The Clinical Value of Albumosuria.

ALBUMOSE is a body occasionally met with in the urine, the clinical significence whereof has not so far been thoroughly worked out; indeed, it cannot be said that we are as yet in possession of sufficient trustworthy data to enable us to appreciate its full importance as a clinical symptom. Its identification in the urine is not always an easy matter though. Should it ultimately prove the means of affording useful information in respect of morbid conditions as yet but faintly interviewed, physiological chemists will doubtless provide us with a readier means of recognising it with certainty. When present in any quantity it is sufficient to drop in enough acetic acid to give a strongly acid reaction to the urine, and then to add an equal quantity of a saturated solution of chloride of sodium. In presence of albumose this gives rise to a copious precipitate which disappears on heating and reforms on cooling. If, as is often the case, the urine also contains albumen, the urine may not clear up on boiling owing to the formation of an albumen precipitate. The significance of albumose as a constituent of urine was first pointed out by Bence Jones, who, in 1848, called attention to the presence in the urine of a peculiar proteid body which was remarkable in that it was soluble in boiling water. He had found that the precipitate which formed on the addition of nitric acid cleared up on boiling. In the case on which his observations were based, the patient was suffering from a peculiar disease of the bones characterised by softening; in other words, by a form of mollities ossium. After the lapse of half a century Dr. Bradshaw has just placed on record elaborate and carefully prepared notes of an almost identical case, and we are now asked to consider albumose as: an abnormal constituent of urine met with chiefly, if not exclusively, in association with a diffuse cellular infiltration of the bones, possibly of the nature of what is sometimes styled diffuse sarcoma. In view of the clinical possibilities which this discovery opens up, it is important that practitioners should be instructed to search for and recognise this obscure substance, the presence whereof is easily overlooked, and the pathological interest whereof remains to be established.

The Special Enlistment Scheme.

A SPECIAL-enlisted recruit into the Scots Guards fell dead on parade at Windsor last week. This untoward occurrence will doubtless have the effect of directing particular attention to the scheme originating with Lord Lansdowne, who is particularly desirous of adding new battalions to the Guards and certain infantry regiments. During the past year these special enlistments increased from 32 per cent to 72 per cent. It will occur to most people, that this wholesale enlistment of men physically incapable of undergoing fatigue duties, or unfit for the full duties of soldiering for the greater part of a year or so after enlisting, may become a very costly one in life as well as money. It unmistakably points to a more serious evil, namely, that a large proportion of the men who join the Army must necessarily be incapable to perform the full duties of soldiering during many months after enlistment should they ever reach, as it is expected they will, to the proper That they will is not implicitly standard. believed by many regimental commanding officers who greatly object to having weakly recruits foisted upon them, and therefore it should be clearly understood whether these specially enlisted recruits are passed by either a duly qualified man or a member of the Army Medical Staff. It is of very considerable importance the public should know whether this unfortunate soldier was, or was not, compelled to do duty for which he proved physically unfit, suffering from a weak heart. Some twenty years ago complaints were rife as to the way in which recruiting was habitually practised, and of the number of youths who were beguiled into premature engagement in the service without contributing permanently to its strength. Medical experience testified how practically unfitted were young recruits to endure the wear and tear of laborious discipline, still less to exposure in foreign climates, ere their frames were knit, or their bones fully consolidated and united. Medical reports at that time frequently came from Netley of the deplorable numbers sent back after a brief service in the Tropics to be treated and subsequently sent back to their homes. Parliamentary inquiry ensued, and among the members of the profession who gave evidence, was one of large experience. The late Professor Sir Thomas Longmore testified that "No rule whatever can be laid down for the height of growing lads between seventeen and twenty years of age, because the diversity is so great; still more, unfortunately, the powers entrusted to the recruiting authorities were so largely used in dispensing with physical qualification, so that the

medical officer finds himself and his advice constantly set aside. In fact, there is still a very excessive waste going on in the Army during the early years of the soldier's career, which is in great part due to a want of strictness in the first enlistment examination." This it will be seen, strengthens the arguments of those who protest against such wholesale special enlistments of young men, more recently sanctioned by the Horse Guards authorities, a considerable percentage of whom never develop into full-grown soldiers. We confess to a desire to know what becomes of the men who break down in the process of development, or otherwise fail to reach the full standard? We are even more curious to know whether this special mode of enlistment was before adoption duly submitted and sanctioned by a properly constituted Army Medical Board?

Interesting Dublin Dispensary Election.

A COUPLE of months since Dr. Usher, who had occupied the position of Medical Officer of the Dundrum and Glencullen Dispensaries for twenty-one years with great credit to himself, presented his resignation of that office, and it devolved on the Committee of these districts to make a new appointment. As the suburb is populous and rising, there were a host of competitors, but the contest resolved itself into one between a Medical Officer who, for twenty years, had occupied the neighbouring district and another practitioner, who had resided in Dundrum for some years and assisted Dr. Usher in his practice. The battle was so even that, in the end, success depended upon a single vote. At the first attempt at election the chairman sought to carry in his candidate by a casting vote, but, this being illegal, another meeting had to be called, and at that meeting, one of the supporters of the Dundrum candidate failed to attend, and, accordingly, the appointment went to the Medical Officer of the neigh-The next day the cause of bouring district. the absence of this gentleman came to light in the shape of a bogus telegram, which informed him that his shooting lodge, far away, was on fire, and calling for his immediate presence. In hot haste he went off, leaving the election behind him, but, when he arrived at the shooting-lodge, found that the message was a hoax. Immediately on his return he lodged a caveat against the election, and strict inquiry was instituted, with the aid of detectives and all the resources of the law, the result being that the Coroner for the Southern division of the County Dublin, who happens to be a member of the committee, and to be also the chairman who had given the invalid casting vote, has been accused of sending the bogus telegram, and has been identified rightly or wrongly, by the Post Office girls who transmitted it, and a writ in damages for the recovery of £500 has been served upon him. Moreover, the Local Government Board has held an official inquiry upon oath, and the verdict waits upon the report of the Inspector, Dr. Edgar Flinn. Interesting questions of law arise under these circumstances, which we may speak of without the least prejudice to any

of the parties to the controversy. First, suppose that it should be proved that the absence of the member of the Committee was obtained by a fraudulent telegram, would that invalidate the election? We think that it would decidedly not do so unless it could be shown that the elected officer was privy to the fraud. Were it otherwise any enemy of a successful candidate might invalidate his election by sending a bogus telegram. It is another question whether it would make a difference if the sender of the bogus missive were a member of the Committee and a known supporter of the successful candidate. Lastly, supposing it were proved in court that a coroner was guilty of this conduct, which, in this case, we do not for a moment believe, would he be removed from his coronership? It is to be recollected that a coroner in Ireland is the elect of the Parliamentary constituency, and therefore irremovable, except by some very special legal authority as to which we do not at present possess adequate information. It is scarcely necessary to add that, so far as the evidence discloses, neither Dr. Usher nor either of the two contestants had any privity with the sending of the inculpated telegram, or were in any way mixed up with it.

School Nominations for the Army Medical Service.

THE Director-General has recently re-issued his invitation to certain colleges, universities, and medical schools to nominate, each, a diplomate for a Commission in the Army Medical Corps, subject to the approval of the War Secretary. The Irish College of Surgeons agreed last week to recommend Mr. Davies, one of its Licentiates, who had served some time as a civil practitioner in charge of troops at the Curragh Camp. There were, we understand, A nomination has also been ten competitors. offered to the medical school of the Catholic University. We have long since pointed out that there are grave objections to this nomination system from the collegiate point of view. In the first place, the Army Medical Officers may very naturally take umbrage at the admission, by a side entrance, to the pale into which they have been obliged to win their way by a stiff competitive examination, and they regard the nomination system as an official expedient to fill up the hiatus in the ranks of the corps which has arisen from the refusal of the authorities to do justice to the medical staff. The Licentiates and Fellows of the colleges, who have been agitating for that justice, will not thank the colleges for having come to the rescue of the authorities just when the victory of the profession is nearly won. Then, again, we cannot regard it as a kindness towards any young man to assist him in entering the Service by the back door. He is, no doubt, grateful at the moment, because he is saved all the delay. expense, and risk of a competitive examination, but we apprehend that he will not appreciate the boon when he finds his method of entry thrown in his teeth by brother officers who dislike or are jealous of him. Say what he may, he cannot get over the fact, and, in

our opinion, the temporary advantage is dearly bought. Lastly, in the interest of the Colleges themselves, we submit that the petty patronage of one or two student nominations for one or two years is not sufficient compensation for involving themselves in personal controversies. It is notorious that these nominations are the subject of contests between rival schools and hospitals, and of importunate canvassing by the personal friends of the competitors, and we feel that no matter how excellent the selection of a nominee may be, the College cannot escape the sneers and abuse of all those who are unsuccessful. We urge that it is altogether beneath the dignity of public institutions of high standing to associate themselves, in any way, with such proceedings, especially as, in so doing, they must accept the responsibility of acting as sponsors for their nominee, and for his professional competency, industry, and personal conduct ever afterwards. We are clearly of opinion that, all things considered, the game is not worth the candle.

A Royal Academy of Medicine of the United Kingdom.

This country is singularly deficient in having no representative medical body comparable to that which obtains among our Continental neighbours. To mention only three examples, an Academy of Medicine exists in Paris, Berlin, and Brussels, and each the centre of much useful activity in furthering the advance of medical science. The proposal to found an Academy in London by the amalgamation of the existing medical societies, as has several times been urged, would not be the same thing. No doubt such a scheme would be useful in centralising and disseminating the work of those who are the mainstay of the societies. But, on the other hand, no special distinction would be conferred upon the worker by submitting his contribution to such a tribunal. Under the present circumstance if any medical investigator alights upon some new discovery in the science of his profession, only one portal is open to him of gaining for it the distinction which it probably deserves, and that is by bringing it before the Royal Society by deputy should he happen not to be a Fellow of that august body. The obvious disadvantage of this position of affairs is that the Royal Society is accorded the credit of being the medium through which the discovery is made known to the world. Thus to a large extent the medical profession is deprived of that honour. Whereas matters in this respect would be very different were a "Royal Academy of Medicine" to stamp with its imprimatur an important and valuable communication upon a subject to which the attention of the whole world could be directed with an authoritative approval. The point which we desire to emphasise here may seem to be a small one, nevertheless reflection must show that medicine stands alone in comparison with other sciences, and there is, therefore, much reason in claiming that it should have a high scientific tribunal of its own, apart from that, like the Royal Society, which is common to all the

sciences. But in another direction a Royal Academy of Medicine might prove of much value. It might be made the means of stimulating young scientists to undertake original work by the offer of prizes, and to gain a Royal Academy prize would be a distinction for which presumably many young workers would strive their best. In brief, if a Royal Academy of Medicine were to be founded it would distinctly fill a gap in our academic system, so far as the medical profession in this country is concerned, and it is impossible to dispute the benefits which it would confer.

The Antiquity of Electrotherapy.

It is curious that foul monster in bloodthirstiness and cruelty as Marat was, and thoroughly deserving, as he was of the death that Charlotte Corday dealt out to him, he yet should have found time in the course of his evil political life to work at such sciences as electricity and light. In his youth he studied medicine for some time, but practiced afterwards as a quack, and in this connection a somewhat curious letter written by him on September 26th, 1783, has just been found and made public. The letter is to the effect that he successfully cured two patients by means of electricity. The nature of the first case is not mentioned, but the second was that of a prominent person who, by the use of electricity recovered his vision, after the sight has been lost for thirty years. The letter then proceeds, "But it is in Spain that I am specially desirous of proving the value of this new remedy; for when employed by a medical man, it is simply admirable." It is, at this date, rather difficult to comprehend why Marat had set his heart upon using his remedy in Spain, but it is quite easy to understand why he should especially imply that the treatment was only to be trusted when administered by medical men. No doubt his object was to prevent quacks from making use of it. Upon the whole, however, we are disposed to doubt the veracity of his statement that a patient had the vision restored by electricity after having lost the sight for thirty years. Nevertheless the fact is unquestionably interesting that Marat employed electricity as a therapeutic agent as long ago as 1783.

A Scientific Literary Poisoner.

THE well-known writer of fiction, Mr. Morley Roberts, achieves an enormous yearly output for the benefit of the publishers and of the world at largethe latter, of course, including himself. His ingenuity of plot is boundless, and one of his latest efforts has been to conceive the idea of two clerks who tried independently to poison their chief, but who used substances that were antidotes the one to the other, so that virtue issued triumphant, and the ungodly fell straightway into the pit. From a note n Literature we find that a similar device was adopted by Dryden in the plot of "San Sebastian." In commenting upon this most ingenious fictional peg one is naturally averse from pouring cold water upon the subtle, yet harmless, imaginings of the fertile novelist. We will be content, therefore, to point

out that the author would do well, in the interests of realism, to arrange matters so that the intended victim should take both bane and antidote within a sufficiently short period of each other to allow of the prosaic chemical processes needful to neutralisation to take place in the stomach before that organ has absorbed the toxic stuff. Shades of Lucretia Borgia! But enough has been said of this tempting subject. By the way, Ausonius—no one less—is said to have hit upon a similar literary device.

"Cassaripe" in the Treatment of Corneal Ulcers.

A NEW remedy in the treatment of corneal ulcers is at present attracting some attention in America. It is known as "cassaripe," and is obtained from the bitter cassava plant. According to Dr. Chandler, the following is the mode of its preparation: - "The natives in making Cassava bread grate the root, whereby a milky juice exudes. This juice is acid, and is supposed to be very poisonous; heat, however, destroys its poisonous qualities, and in a concentrated semi-solid form the juice is known as "Cassaripe" Dr. Chandler adds that in certain parts of the Tropics the drug is used as a preservative agent for meat, and it was this fact which suggested its employment in corneal ulcers. In large sloughing ulcers in old persons cassaripe is said to have yielded excellent results. It may be used, in combination with atropine and eserine. Judging, however, from the reference to the drug in the American Practitioner and News (February 1st, 1899), some difficulty has been experienced in obtaining it by those so far desirous of putting its qualities to the test. Apparently its value seems to lie in the fact that it is an antiseptic, and if so, the reasonable conclusion is that any antiseptic used in the treatment of a sloughing ulcer of the cornea would be likely to be similarly beneficial.

A Proposed Centenary Celebration of the Royal College of Surgeons, England.

A MATTER of some interest was discussed at the last ordinary meeting of the Council of the College of Surgeons, England, with reference to the advisability of celebrating the hundredth year of the incorporation of the College. The centenary event occurs next year, the date of the first charter being 1800, and it has suggested itself to Mr. Bryant and others that steps should be taken to signalise the occasion by means of some celebration. A committee of the Council has been appointed to take the matter into consideration, and report thereon at a subsequent meeting of the Council. We cannot doubt that a function of the kind could be made very attractive, and would meet with the general approval of the Fellows and members of the College.

THE Public Health Committee of the Hackney Vestry have issued a circular calling the attention of the public to the contagious nature of consumption and offering to disinfect all rooms, free of cost, after the death or removal of phthisical patients.

The Perils of Judicial Garrulity.

It is always to be regretted when a Judge on the Bench allows his personal views to induce him to diverge into unnecessary, and often inconvenient loquacity. He may have much to say which would be appropriate at a dinner table, and it may be excellent sense derive from special knowledge of circumstances. But the Bench is not, in the opinion of the public, an elevation from which to crack jokes or interchange chaff with lawyers, or to sermonise. From it the public expects to hear exposition of the law and of the evidence, and not moral disquisitions, however great the temptation may be to give voice thereto. Judges advancing in life are particularly prone to this sort of thing, and we could name several who never can refrain from little humourous or didactic diversions. Mr. Justice Boyd, in the Dublin High Court, last week, favoured us with one of these totally unnecessary digressions in deciding a paltry motion to remit an action for damages to a Affidavits were presented for and against the application by Sir William Stokes and Mr. H. G. Croly, and the learned Judge is reported to have said that :-

As a rule he did not place much reliance in doctors' certificates or statements. The only statements which could be accepted were those of barristers, because they were bound by authorities, but doctors were not bound by any authorities. All these gentlemen could state what they liked, but unless they were pulled up by some acute person on the other side they would have it all their own way. However, Surgeon Croly had given evidence of serious injuries in the case, and, as it was not his Lordship's duty to determine the truth or otherwise of the affidavit, he should refuse the motion.

If, as his Lordship says, it is not his duty to determine the truth or otherwise of an affidavit from a medical witness, it, certainly, is not his duty to insult the witness by proclaiming doubts of his veracity; still less has he any right to asperse the whole medical profession as, in a general way, a pack of liars. If it were left to public opinion to arbitrate as to the relative reliability of the statements of the medical profession and of Judge Boyd's own profession there can be no reasonable doubt which way the verdict would go. We hope we may regard this pronouncement of the learned judge as the result of a temporary aberration, and that he now regrets what he is reported to have said.

Poisoning Mystery at Leavesden Asylum.

A CORONER'S inquiry was held on March 18th, regarding the death on March 14th, of Caroline Ansell, et. 26, an epileptic inmate of the institution. The circumstances attending the death of this girl are somewhat peculiar for an asylum, and have given rise to many surmises and sensational reports. According to newspaper report, the deceased received on the 9th through the post a parcel containing a cake. She partook of this, giving some to four other women, and soon after they all complained of pains, and vomited. Ansell died on the 14th. Some time before this she received a letter purporting to

have been written by a cousin, informing her that her mother was dead, but this news was false-These are the facts; the rest is conjecture. Was the poison intended indirectly for one of the nurses, on the supposition that the patient would be sure to offer her nurse a slice of the cake? Was the crime the act of a discharged patient? Who wrote the letter? Should the letter in the possession of the police not be photographed and published in the hope of establishing a clue? Was it really a case of irritant poisoning as alleged, or was death due to natural causes? Did the patient Ansell herself convey the poison? One paper remarks that "the idea of the woman having poisoned the cake is not so far fetched as might at first sight appear. Carbolic and oxalic acids are both used in the asylum." These are examples of questions and surmises running through the public prints. We are surprised to read that oxalic acid is in use in the asylum, and would like to know if it is true, and if so, if such a deadly poison, which can so easily be mistaken for other salts, is indispensable in the institution? Meanwhile, further comment may prudently be held over.

The Chloroform Burglar Bogey.

An enterprising evening contemporary—to wit, the Star-has taken the trouble to interview Dr. Meadows, of chloroform burglar fame, in reference to the remarks we made last week on the absurdity of the tale as related in the columns of the Star. Dr. Meadows is reported to have declared his readiness to chloroform the writer by means of a saturated pocket-handkerchief pushed under the door, adding that he had done it himself with cats and dogssurely a rather suspicious admission for one who lies under the imputation of having set affoat a story at which everyone who has any experience of chloroform must laugh. How much chloroform would be required to saturate a handkerchief? Barely enough to induce unconsciousness in the hands of a skilled ancesthetist at close quarters. Yet we are asked to believe that this quantity sufficed to induce deep sleep in a room through which a tolerably free passage of air was presumably taking place, apart from the fact that chloroform vapour, being very heavy, would tend to creep along the floor and to disappear up the chimney. The whole story is too preposterous for serious discussion, and is worthy of the novelists who, without having taken the trouble to look up the subject, chloroform their heroines with an ease and a promptitude which may amuse the groundlings, but must make the experienced man smile. Under these circumstances, we can only suggest that the Editor might find out (a) exactly how much chloroform was taken out of the stock bottle; (b) whether the thief took anything beyond the doctor's trousers; (c) what view the police hold as to the house having been entered by thieves, and upon the affair generally. As to personal advertisement the possibility hardly applied at the time of our previous remarks, when the name of the medical man concerned had not transpired. The Star itself has shown that the contingency is not altogether remote

by its detailed interview, and challenge of half a . column in length. The burden of proof, anyway, lies with those that father such an extraordinary tale.

A Proposed Seamen's Hospital for Cardiff. THE Mayor of Cardiff has embarked upon a useful and praiseworthy scheme-namely, that of building and organising a Seamen's Hospital for the town. Already the sum of £16,500, including a generous donation of £10,000 from Lord Bute, has been raised but £5,500 more are required before the work can be proceeded with. Cardiff is a wealthy town, and there is every probability that this sum will soon be forthcoming. Moreover, the object is so good a one that there can be no excuse for those able to do so from withholding their liberal support. The important shipping centre which the town has now become makes the needs of a seamen's hospital almost imperative, and hence the activity and enthusiasm displayed by the townspeople in the mayor's enterprise. It is proposed to hold a bazaar in aid of the building fund in December next. We wish the new charity every success.

Pharmaceutical Penalties in Ireland.

WE have already called attention to the difficulty which the Pharmaceutical Society of Ireland experiences in its efforts to enforce the law against unqualified dispensing which Parliament has entrusted to it. The Society finds no trouble in detecting or proving the offence, or in obtaining a legal judgment for the £5 set down in the Act as the statutory penalty, but for some reason, which Dublin Castle has never attempted to explain. the authorities have set themselves in a position of hostility to the Society, and make use of the Royal prerogative to protect the misdoer by reducing the fine, the effect of which proceeding is that the Society is heavily mulcted in costs, and, in fact, pays the penalty instead of the law-breaker. Obviously, if this policy is maintained the Society will have to abandon the attempt to protect the public.

Alleged Sectarianism of the Royal College of Surgeons, Ireland.

THE flat con radiction of the statements of Mr. MacArdle respecting the alleged religious bias of this college, which we published recently, has been convincingly confirmed by letters which have appeared in the Dublin papers from the pen of the Vice-President, Mr. Myles, and also of his four Catholic colleagues on the College Council which public statements present practically the proofs which we offered, that Mr. MacArdle's assertions were totally at variance with the facts. Our list of Catholics holding office in the college was in fact shorter than it ought to have been, inasmuch as it omitted mention of Drs. Alfred Smith, Edgar Flinn, and Daniel Corbet, who at this moment hold office as Examiners, though they are all Catholics. It may be added that, within the last week, the College Council has nominated a Catholic for Commission in the Army Medical Corps, though there were many eligible competitors of other | known and successful practitioner who, throughout a

religions, and we fully believe that, to most of the College Council, this gentleman's religion was unknown. It can scarcely be agreeable to a public lecturer to have his deliberate utterances contradicted in every essential particular.

Presidency of Queen's College, Galway.

PROFESSOR ALEXANDER ANDERSON, formerly Fellow of Sidney Sussex College, Cambridge, and now Professor of Natural Philosophy in the Queen's College, Galway, has been appointed president of that college in the room of Dr. Starkie, who has recently been chosen as Resident Commissioner of Education in place of Sir Christopher Redington deceased. The appointment is especially interesting because, as we believe, this is the first time that any one but a Catholic has held the Presidential office in this college,

The Presidency of the Royal College of. Physicians of London.

THE coveted position of President of the Royal College of Physicians of London, vacated by Sir Samuel Wilks after three years' tenure, has fallen to the lot of Dr. Church, who has been duly elected thereto. The choice of the Fellows will, we feel sure, meet with general approval, Dr. Church combining in his person the physical and intellectual qualities which go to constitute a strong president. Of austere, yet not unfriendly, demeanour, of stalwart frame and deliberate utterance, Dr. Church is eminently adapted to adorn a post in which scholarship and business capacity must go hand in hand. Once again we congratulate the Fellows on their choice, and wish the new President a long and successful career as the foremost representative of medicine in the metropolis.

Women Inspectors of Nuisances.

THE experience of the Southwark Vestry with their woman inspector of nuisances has, we learn, proved so far satisfactory that another is shortly to be appointed whose duty it will be more particularly to inspect factories and workshops in the parish. The remuneration, as things go, is fairly good, the salary being £110 per annum, rising by £10 to a maximum of £150.

An inquest was held a few days since at Hackney on the body of a woman who had succumbed to hæmorrhage from abortion after taking some medicine prepared by the notorious Madame Frain. The jury added a rider to their verdict to the effect that Madame Frain's business was "either fraudulent or felonious," a truism which we commend to the notice of the authorities. The custom of leaving the prosecution of these people to private initiative is one which reflects little credit on the police, to whom it properly belongs to decide under which head they ought to be dealt with.

WE regret to have to announce the death of Dr. John Brunton, of Endsleigh Street, W.C., a welllong and busy career, found time to make numerous interesting observations which saw the light in the journals and at the various medical societies. He held a large number of valuable appointments.

WE understand that the Surgeoncy of Dr. Stevens's Hospital, Dublin, has been vacated by the resignation of Mr. Edward Hamilton, who has so long and honourably occupied the position. There is already an animated competition for the place, which secures to the holder an excellent surgical status in Ireland.

A BALL for the benefit of the National Consumption Hospital in Ireland will be held at the Rotunda, Dublin, on the 19th of April. The Lord Lieutenant and the Countess Cadogan have promised to be present.

THE Royal Academy of Medicine of Ireland has decided to convene an aggregate meeting of the profession, and has invited the Medical Authorities and Societies to name two delegates each. The preliminary conference will be held on the 13th of April at 4.30 p.m., at the Royal College of Physicians.

PERSONAL.

Dr. Allen McLane Hamilton, of New York, has been elected a Fellow of the Royal Society of Edinburgh.

Dr. John Macpherson, Medical Superintendent of the Stirling District Asylum, Larbett, has been appointed Commissioner in Lunacy for Scotland in the room of Dr. Sibbald, who has retired.

Mr. G. Vere Benson, M A. Cantab, M.R.C.S., L.R.C.P., who has been fulfilling the duties of Deputy-Coroner for West Middlesex, was last week elected Coroner for the Lewes Division of the county of Sussex.

M. HAFFKINE, C.I.E., is about to leave India on sick leave, and come to London. During his visit to England he will read a paper before the Royal Society, in connection with his inoculation treatment.

THE Queen's oldest honorary physician by many years is Sir Alexander Armstrong, who was appointed to the post forty years ago. He was engaged for several years in searching for Sir John Franklin in the Arctic regions.

Dr. David Wallace. of Beckenham, who was recently acquitted at the Maidstone Assizes of a serious charge, was presented last week with a purse containing £60, which had been subscribed for by the members of friendly societies of Penge and Beckenham, as a mark of esteem for services rendered by him to the clubs.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

Dr. John Sibbold.—Dr. John Sibbold, in virtue of the unalterable rule appertaining to holders of Government

offices on attainment to the age of sixty five, has had to sever his long connection with the Lunacy Board of Scotland, of which for some time back he has been the Senior Commissioner. Dr. Sibbold has in a quiet way done a great deal of work in the cause of the treatment and housing of lunatics in Scotland. Graduating at Edinburgh University in 1854, he was appointed a Deputy Commissioner in Lunacy in 1870, after holding for eight years the superintendentship of the Argyll and Bute Asylums. In another eight years he became a full Commissioner, and for the last twenty-one years he has filled this office. His attention has chiefly been directed to the proper construction and arrangement of asylums, and his papers on the subject have influenced in great degree the arrangement and planning of the more recently built asylums in Scotland. For some years Dr Sibbold has been regularly elected to the Council of the Royal College of Physicians of Edinburgh, for which his services it is hoped will still be available.

THE RESIDENCY IN THE ROYAL EDINBURGH INFIRMARY.—The managers of the Royal Infirmary of THE RESIDENCY Edinburgh, wishing to provide sleeping accommodation for three of the house physicians and surgeons at present non-resident in the hospital, and being rather hampered by the lack of available space, propose to carry out a series of evictions before the summer. Their plan of campaign appears to be most ill-advised and arbitrary. Each resident medical officer has at present a small sitting-room immediately adjoining his still smaller bedroom, while there is one common room for mess purposes. The managers intend to deprive the coming residents of their sitting-rooms make some of them into bed-rooms, and form a "reading and visitors' room" common to the whole staff in place of the former private rooms. In this room they will be supposed to do their reading and to entertain their visitors; the second use the room is to be put to being highly conducive to the proper quiet so necessary for the first The proposal seems really to be the outcome of mental aberration on the part of some one in authority who thinks the resident-staff are well provided if beds are given them, common rooms devoid of furniture, save a wooden table or two and some chairs, and no sitting-room where privacy and quiet are possibly attainable. The present residents have memorialised the Board on behalf of their successors and the Honorary Medical and Surgical Visiting Staff held a meeting on Monday to consider the matter. A senior public schoolboy has his study as well as his bed-room or cubicle; and it is a most ill-judged curtailment of the comforts offered by the residency, at present more akin to a licensed lodging-house than a home for followers of Æsculapius—officials who have to work hard, and ought at least to be able to seek solitude elsewhere than in a contracted bedroom either for rest, reading or meeting friends.

St. Mungo's College.—The closing meeting of the winter session took place on the 24th inst., when the medals and certificates were delivered to successful students. It is satisfactory to note that year after year the number of students attending the College is on the increase; in 1889-90 the number was 94; in 1894 95, 98; and for the past session, 108.

The New Lunacy Commissioner,.—Dr. John Macpherson, Medical Superintendent of Stirling District Asylum, Larbert, has been appointed Lunacy Commissioner for Scotland, in room of Dr. John Sibbold, who has retired. Dr. Sutherland, Senior Deputy Commissioner, in his application for the vacant post, based his claims in part on the unbroken precedent of the promotion of the senior deputy Of course, like most such appointments, politics have, perhaps, a great deal to do with the result, and also in the breaking of such precedents, and Dr Sutherland may remember that he secured his Deputy Commissionership through Sir George Trevelyan. If it is any satisfaction to Dr. Sutherland we may console him by saying he is not the only disappointed one, as it was confidently expected that a Glasgow man would secure the post, and no doubt many a pious prayer has been uttered in favour of the Secretary for Scotland.

GLASGOW ROYAL INFIRMARY RE-CONSTRUCTION — DISSENSION IN COMMITTEE.—It has been said from

appearances and attitudes assumed by some members of the Committee and the stand taken by the staff, the Lord Provost is not likely to enjoy the gratification of seeing his scheme for the reconstruction of the Royal Infirmary as a memorial of our Queen's Jubilee practically realised before his term of office as Lord Provest to the City expires. Trouble, it is said, has been brewing for some time in the Executive Committee which may bring matters to a crisis at any time, and as a sign of the position of affairs several members have withdrawn from the Committee. There may be faults on both sides, but when a member of Committee who subscribed £1,000 to the fund retires, we must advise caution at least, especially when it is an open secret that certain matters in the infirmary have been pre eminently critical from the very beginning. The present deadlock is to be regretted in more ways than one, especially when it is remembered that the fund is still short of about £20,000 of the estimated sum, and the fact that money has ceased to come in—this latter fact is looked upon as a very serious indi-cation of things, so much so that begging circulars are being, and have been, sent out soliciting funds, and, in order to succeed, collectors are employed who must be paid, as such gentry are not at all inclined to give their time and service gratuitously. The scheme was launched exactly two years ago, and on April 28th, 1897, upwards of £50,000 had been subscribed, which has since then come up to between £70,000 and £80,000, the minimum sum aimed at being £100,000. The best thing would be a general meeting, at which the whole facts of the case could be brought before the notice of the subscribers and calmly discussed, and an endeavour made to get out of the difficult position.

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last was devoted in part to a paper by Dr. Maguire on "Deaths from Functional Nervous Disease." He related four cases in which more or less prolonged unconsciousness without any other morbid sign was followed by death without anything being discoverable post-mortem. He maintained that these deaths were due to exhaustion of the grey nerve matter.

Dr. Sansom instanced various analogous conditions such as epilepsy and angina pectoris in which nothing could be found to account for death. He suggested that the grey matter as a whole was not affected, but perhaps paralysis of the vagus might afford an explanation. He mentioned casually that fatty degeneration of the heart was an extremely rare cause of sudden death.

Dr. Tuke thought the author's cases bore some resembalance to the early stage of general paralysis; and Dr. Richards questioned whether an affection of the cortex, capable of determining such serious symptoms, could exist without leaving some microscopical evidence thereof.

Mr. Battle mentioned the case of a woman, et. 30, with severe symptoms, suggestive of gastric perforation in which, after death, no lesion was anywhere discovered.

Dr. Maguire pointed out that paralysis of the vagus would not account for the unconsciousness.

The remainder of the evening was alloted to Mr. H. L. Barnard, who discussed "Certain Points in the Pathology of the Pericardium." He observed that the pericardium formed an integral part of the mechanism of the venous circulation which was largely carried on by the contraction of skeletal muscles. In violent exertion a large quantity of blood might be suddenly forced into the right heart. This, but for the tough fibrous pericardium, would hopelessly stretch and dilate the thin walls of the heart which, however, was supported thereby just as the leather case contained the foot-ball. He had shown by actual experiment that the pericardium limited about one half the capacity of a heart in diastole. He insisted on the importance of a well-developed abdominal muscular system in assisting the passage of the blood upwards from the great abdominal veins. In pericarditis causing softening of the pericardium any effort might be followed by strengthening which was probably permanent.

Correspondence,

We do not hold ourselves responsible for the opinions of our correspondents.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The attention of the Council of the Medical Graduates' College and Polyclinic has been directed to an article in your journal of March 22nd, 1899, in which it is stated that "matters are by no means going smoothly among the powers that be at the New Polyclinic in Chenies Street, W.C. It is the same old story, a striving after the position, to use a vulgar expression, of 'boss of the show.' Thus two camps have been formed, one represented by a well-known surgeon, and the other by a specialist, and a struggle is now going on for the mastership."

The assertions contained in this statement are altogether inaccurate. No deliberative body, such as the Council of the Medical Graduates' College, can carry on its proceedings without the discussion upon many points regarding which various and different opinions may be held among its members. In the proceedings of this Council differences of opinion have given rise to debate, but the differences have been such as arose from the determination of the Council to carry out the best measures for the success of the College, not for the supremacy of any person or persons.

The instruction to send to you this rectification has been entrusted to me by a unanimous vote of the

Council.

I am, Sir, yours truly,
WILLIAM M. ORD, M.D., Chairman of Council.
22 Chenies Street, Gower Street, March 25th, 1899.

THE DANGERS OF ERYTHROL TETRANITRATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIE, - An accident, by which a chemist lost his life, happened at a tabloid factory at Dartford, on December 15th, 1897. He was engaged in mixing tetranitrate of erythrol with finely powdered lactose in a mortar when an explosion occurred.

Again, at the end of 1898, an accident was caused by tetranitrate of crythrol being inadvertently thrown into

a fire, and one person was injured.

Tetranitrate of erythrol is possessed of explosive properties, and is highly sensitive, more so indeed to percussion than dynamite or gun cotton. As it has lately come into some use in the place of nitro-glycerine as a remedy for angina pectoris, I should be glad if you would draw special attention in your paper to the dangers attending the handling of this drug.

I have the honour to be, Sir,
Your obedient servant,
A. Ford, Colonel,

H.M. Chief Inspector of Explosives.

Home Office, Whitehall, S.W., March 24th, 1899.

POOR-LAW MEDICAL SERVICE REFORM.

DEPUTATION TO THE LOCAL GOVERNMENT BOARD.

On Thursday, March 16th, the deputation nominated by the public meeting which was held in the Royal College of Surgeons waited on the Local Government Board. The deputation consisted of the following members:—Sir Thornley Stoker (President Irish Medical Association), Dr. John William Moore (President Royal College of Physicians), Surgeon Swan (President Royal College of Surgeons), Sir William Stokes, Sir William Thomson, Dr. Truell, D.L., Ashford, Co. Wicklow; Dr. Donnelly, Dublin; Dr. Stanley B. Coates, Belfast; Dr. Neale, Mountmellick; Dr. Oulton, Dublin; Dr. Joseph Smyth, Naas.

The deputation were received by a full board, the secretary being also present.

Sir Thornley Stoker, who introduced the deputation, said they came on behalf of the Poor-law medical officers with the authority of the largest meeting of the Irish medical profession that had ever been held in Ireland. The reforms they asked for were most reasonable. The grievances they complained of worked great injustice to the doctors, but still greater injustice to the sick poor. The first, and far and away the most important and

urgent of all, was superannuation.

Surgeon Swan, President of the Royal College of Surgeons, emphasised the importance and urgency of superannuation. He asked: (a) The Local Government Board, in view of their official knowledge of all the circumstances, to exercise their influence with the Government to support the Medical Officers' Super-annuation Bill (Ireland), 1899; (b) and further, to exercise their own powers to meet cases of lesser disability due to advancing years and length of service by providing that a dispensary doctor of more than thirty years' service and over sixty years of age should be enabled to have an assistant medical officer for his district on payment by him of such portion of the assistant's salary as the Local Government Board should determine. He pointed out how the sick poor were wronged when they were left dependent for medical relief in their necessities on a doctor who was physically unable to attend them in the night time, or when the journey was difficult or the weather inclement, or the work unusual. He illustrated this from his own personal knowledge, when the dispensary doctor was absolutely unable to do his duty, was denied superannuation, and was too poor to retire.

Dr. Joseph Smyth, Naas, said the Local Government Board were naturally the responsible advisers of the Government on this question. If the Local Government Board were of opinion that compulsory superannuation, though good in itself, had its necessity outweighed by other considerations, then superannuation would be delayed. But if they considered, as he believed they did, that a dispensary doctor who had passed the retiring age was in most cases physically unable to efficiently discharge the duty of an Irish dispensary district under all circumstances of difficulty in all kinds of weather, and at any hour of the night, and if they so advised the Government, not as a counsel of perfection, or simply of betterment, but as an imperative necessity, which the sufferings and lives of the sick poor demanded, then he believed that superannuation would become law during

the present sessions of Parliament.

Sir Thornley Stoker asked the Local Government Board when, for reasons of public policy, dispensary districts are deprived of one or more electoral divisions, that the medical officers of such districts shall be protected against any diminution of their present salaries.

Dr. Truell, D.L., supported the request.

Dr. John William Moore, President Royal College of Surgeons, asked the Local Government Board to "regulate" the salaries of dispensary districts, so that the medical officers may be remunerated for the cost they are obliged to incur in travelling on dispensary duty. He complained of the anomaly and injustice of making the dispensary doctor pay out of his pocket so large a portion of his small salary for doing public work. He gave the case of a doctor in the west of Ireland who was obliged to keep two horses for the actual requirements of dispensary duty. His salary was only £110 a year, and his district was over 80 square miles. There were several others in the west still worse off. He showed how this must necessarily deprive the sick poor of their full measure of medical attendance, and he therefore urged, in justice to both the doctor and the sick poor, such regulation of the salaries as would provide for the cost of travelling

Sir William Thomson said the public had no right to the use of a dispensary doctor's horse without payment. In many places a horse would not be sufficient to do the travelling required by the dispensary duty. There were districts to his own knowledge where the private practice did not exceed about £25 a year, though that was an extreme case. If in such a district the doctor decided

to do his work on foot just as far as he was able, there was no power to compel him to provide a horse, and the sick would necessarily be neglected.

Sir William Stokes asked the Local Government Board to have printed on the face of each visiting ticket, as is done in England, the following words: "If this ticket be not presented before noon on the day of its date the medical officer will not be expected to visit the case that day unless the word 'urgent' be written on it"; (b) and to specify the procedure to be followed where their rules were not observed, as for example where tickets are not filled and signed by the issuer, where the issuer, instead of exercising due diligence in ascertaining whether the applicant be a "poor" person or not, shows gross negligence or otherwise misuses his power; and to suggest that this procedure should direct the medical officer to report the circumstances to the Clerk of the Union, who should then be responsible for the remainder of the proceedings, so as to avoid as far as possible personal conflict between the issuer and the medical officer. He said the abuses of the ticket system had been a scandal too long permitted. Visiting tickets sometimes given recklessly. He knew a within his own personal knowledge where the dispensary doctor was obliged to travel ten miles on a red ticket to find that it was not for a human being at all he was wanted, but actually for a pig. He held in his hand a letter from a dispensary doctor in a different county, which stated that he had received two visiting tickets, one for a cow and the other for a donkey. The one for a cow was filled in in the owner's name, 18 miles away. The second, for a donkey, was also in the owner's name, four miles away, and was signed by the chairman of the Committee,

Dr. Coates, Belfast, said they felt it a very great hardship to have visiting tickets dropping in at all hours of the evening and night without the slightest necessity. They were always ready to give their services without complaining, no matter at what hour, when there was reasonable cause, but they asked to be protected against this abuse. He handed in a visiting ticket such as is issued in England.

The Vice-President, in replying, said the Local Government Board would give the questions submitted to them careful consideration. They were bound to look at them from all sides, and to act in the interests of the public.

Medical Fees in Law Courts.

REPLYING to Dr. Farquharson's question, whether the Government would consider the question of revising the scale for medical evidence with the view of more adequately remunerating the services of medical men who were compelled to give evidence, Mr. Jesse Collings replied that for the present the Secretary of State does not see his way to alter existing arrangements.

Chelsea Physic Garden.

UNDER the scheme of the Charity Commissioners the Physic Garden at Chelsea will be saved from the hands of the builders, the ground having been handed over to the Trustees of the London Parochial Charities on an agreement that they shall dedicate £800 a year for the maintenance of the Garden, which is to be administered exclusively for the promotion of the study of botany, with special reference to the requirements of general education, scientific instruction, and research." The practical management of the Garden will be vested in a committee formed of representatives nominated by the Trustees of the London Parochial Charities, the Treasury, the Lord President of the Council, the Technical Education Board, the Royal Society, the Society of Apothecaries, the Royal College of Physicians, the Pharmaceutical Society, the London County Council, and the Senate of the University of London. Earl Cadogan and his successors, as representing Sir Hans Sloane, who conveyed the Garden in 1722 to the Apothecaries' Company in trust for the encouragement of botany, is a member of the committee.

H.R.H. THE DUKE OF CAMBRIDGE, K.G., has graciously consented to preside at the annual dinner of the Sanitary Institute, to be held at the Whitehall Rooms on May 2nd.

Aotices to Correspondents, Short Letters, &t.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

BEADING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS .- Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

OBIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper on'y, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Spes.—The facts of the case, if true, should be brought under the notice of the General Medical Council.

M.D., F.B.C.P.—Our correspondent will find that the case is dealt with editorially in another column.

THE NEW ORDER OF OPTICIANS.

A CORRESPONDENT sends us the circular of a certain city tradesmen who styles himself "F.S.M.C., Sight Specialist, Certified Ophthalmic Optician by Examination." Who would suspect that the substantive qualified by these adjectives merely kept a shop for the sale of spectacles?

Mr. Kensman.—We do not recommend either specialists or general practitioners, in accordance with our rule. But surely our correspondent need not hesitate to take the advice of a friend as to the best medical man to consult in his neighbourhood.

A QUERY.

M.D. asks whether the central figure in the celebrated painting, "The Doctor," by Luke Fildes, R.A., is the portrait of any living medical practitioner.

J.B. Hydatid cysts of the parotid have been known to occur. A case of the kind was recently recorded in the transactions of the French Anatomical Society.

DR. OKELLY - Unavoidably crowded out.

EXPRETUS.—Any good book on toxicology will be sufficient. Among other methods of treating carbolic acid poisoning trial may be made of camphorated oil, administered by the mouth. It is stated that camphor is an antidote to the acid.

CONSULTATION WITH HOMEOPATHS.

F.R.C S. writes:—"I have been asked by a homospathic practitioner to arrange to meet him in consultation with a view to operating upon a lady patient of his. What is the medical effquette in such a case?"

[The case being a surgical one we think that our correspondent would not be offending any ethical rule in acquiescing in the request, especially since the Royal College of Physicians (London) have refused to lay down any rule definitely deciding that it is unethical to meet a homeopath in consultation.-ED.]

L.R.C P.Ed.-If our correspondent will refer to the last week's of THE MEDICAL PRESS AND CIRCULAR he will find the subject fully discussed.

M.R.C.P. - Professor Osler of the Johns Hopkins University is not an American, but a Canadian, and formerly held the post of Professor of Medicine in the University of Toronto. He has accented the invitation to deliver the Cavendish Lecture before the West London Medico-Chirurgical Society, on Friday, June 16th, 1899.

Acarus .- We have not before met with the term "senilophobia, MARUS.— We have not before met with the term "senilophobia," but the fear of growing old is certainly a widespread disease, if disease it can be called. It affects chiefly persons of the female sex, and it is characterised by a tendency to relapse on slight provocation. The prognosis on the whole is favourable in the absence of complications.

THE GREATEST COLD EVER RECORDED

PROFESSOR DEWAR, by the agency of liquified hydrogen, has reduced temperature to 234 degrees below the Centigrade Zero (which is equivalent to 336 below the Fahrenheit Zero, no temperature like this having ever previously been recorded. By the way, asks a correspondent, Is there any good reason why English scientists should persist in adhering to the Fahrenheit scale which is, admittedly, based upon an original error? Fahrenheit was not an Englishman, and, therefore, we need feel no jealousy in adopting the Centigrade scale, unless there be some technical difficulty which scientists can produce.

Bacancies.

Belgrave Hospital for Children.—House Surgeon for six months.
Board and residence provided and a gratuity of £5 given.
Central London Ophthalmic Hospital.—House Surgeon. Besidence,
board, &c., in the hospital.
Charing Cross Hospital.—Bacteriologist to the Hospital and Lecturer on Bacteriology at the Medical School.

Chester County Asylum.—Junior Assistant Medical Officer, unmarried. Salary £120 per annum, rising yearly by £10 to £150, with board (no liquors), lodging, and washing. Also Medical Officer to act principally as Pathologist. Salary £150 per annum, with board (no liquors), lodging, and washing.

Dental Hospital of London Medical School, Leicester Square.—
Demonstrator in Dental Surgery. Honorarium of £25 per year given.

given.

Derby County Asylum, Derby.—Assistant Medical Officer. Salary
£100, rising to £120, with board, lodging, and washing.

East London Hospital for Children and Dispensary for Women.—
Medical Officer for the casualty department for six months.
Salary at the rate of £100 per annum.

Fisherton Asylum.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to Dr.
Finch, the Asylum, Salisbury.

Hospital for Diseases of the Chest.—House Physician for six months.
Salary at the rate of £40 per annum, board, lodging, and

Salary at the rate of 240 per annum, board, lodging, and washing.

wasning.

London Temperance Hospital.—Assistant Resident Medical Officer six months. Residence in hospital, board, and washing provided, and honorarium of 5 guiness given conditionally.

North Biding Asylum, York.—Junior Assistant Medical Officer. Salary £100, rising to £150, with board, lodging, washing, and attendance.

North-West London Hospital.-Honorary Anæthetist for twelve

North-West London Hospital.—Honorary Anæthetist for twelve months.

Boxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished quarters, board, washing, and attentance.

St. Paneras Workhouse with Infirmary Wing.—Assistant Medical Officer for two years. Salary £120 the first year and £135 for the second year. Residential allowances for a single man provided. Applications Clerk to Guardians, Vestry Hall, St. Paneras Road, N.W.

Victoria Hospital, Folkestone.—House Surgeon. Salary £30 per annum, rising to £100, with board, residence, and washing.

West London Hospital, Hammersmith Road.—Assistant Physiciane Westminster Hospital. Resident Obstetric Assistant for six months.

Board and residence in the hospital provided.

Appointments.

BURT, W. C., L.R.C P.Lond., M.R.C.S., has been appointed Medical Officer to the Workhouse of the Torrington Union.

DEARDEN, V. G. S., L.R.C.P.Edin., L.F.P.S.Glasg., Medical Officer Carbrook Sanitary District by the Sheffield Board of Guardians.

DUN, ROBERT CRAIG, M.B., C.M., B.Sc.Edin., M.R.C.S.Eng., L.R.C.P.Lond., Honorary Surgeon to the Liverpool Infirmary for Children.

for Children.

FULLERTON, ROBERT, M.D., C.M.Edin., Honorary Consulting Surgeon to the Greenock Infirmary.

MACKENZIE, D. J., M.D.Aberd., C.M., Medical Officer of Health by the Glossop Dale Rural District Council.

MUSSON, A. W., M.B., B.C.Camb., Medical Officer to the Work-house of the Clitheroe Union.

O'DONNELL, JOHN M.B., B.Ch Irel., Assistant Physician to the Mater Misericordiæ Hospital, Dublin.

TROMPSON, J. H., L.B.C.P. Irel., L.B.C.S.Edin., Medical Officer of Health by the Mytholmroyd Urban District Council.

THORNTON, Dr., Medical Officer of the Ilfracombe Sanitary District of the Barnstaple Union, vice A. A. Mackeith.

WARDEN, A. A., M.D.Glasg., Private Assistant to Dr. Doyen, of Paris.

Paris.

FAITS.

WEIGHTMAN, E. J., M.B., C.M.Edin., Resident Medical Officer of the Waiton Workhouse of the West Derby Union.

WHITFIELD, ARTHUR, M.D.Lond., M.R.C.P., Assistant Physician in Charge of the Skin Department to King's College Hospital, London.

Births.

GEORGE.—On March 15th, at St. John's Wood Road, N.W., the wife of Isaac George, L.R.C.P.Lond., of a son HARPER.—On March 18th, at Rosary Gardens, South Kensington, S.W., the wife of James Harper, M.D., of a son. Rocers.—On March 18th, at The Red House, Cliffe at Hoo, Kent, the wife of Arthur B. Rogers, surgeon, of a daughter.

Marriages.

COOK—MADDOX.—On March 25th, at Christ Church, Hampstead, John Howard Cook, M.S., F.R.C.S., youngest son of the late William Henry Cook, M.D., of Hampstead, to Ethel, youngest daughter of Mr. George Maddox, of Gainsborough Gardens,

Hampstead,
GRIFFITHS—LEWNS.-On March 20th, at St. Gabriel's Church,
Willesden Green. London, N.W., William Griffiths, B.Sc.,
M.D., Lond., of Grosvenor Gardens, Willesden Green, to Ada
Carrie, third daughter of Charles Frederick Lewns, of Grosvenor
Gardens, Willesden Green.

Beaths.

BRUNTON.—On March 25th, suddenly, at 16, Endaleigh Street, London, W.C., John Brunton, M.A., M.D., aged 63 years.

Clarke.—On March 17th, at Horsman's Place, Dartford, Thomas Furze Clarke, M.R.C.S., aged 43 years.

Port.—On March 25th, Heinrich Port, M.D., FR.C.P., of 48, Finsbury Square, E.C., hon, physician of the German Hospital, Dalston (late of Nuremberg).

Pound.—On March 23d, at sea, on board the B.I.S. Navigation Company's ship, 'Goa,' Clement Pound, L.R.O. P. Lond., son of the late Dr. G. Pound, of Odiham, Hants, aged 38 years.

"The predominance of Magnesium Sulphate and the presence of Lithium in APENTA WATER having been recently pointed out by Professor Pouchet, I determined to ascertain for myself the properties of this water, and for this purpose I prescribed it to a large number of my patients.

"is an excellent, very active purgative, and of strictly constant composition. Its action is mild and reliable, and a wineglassful or half a glass acts as an aperient without producing either griping or discomfort. It is the Water specially suited for the treatment of habitual constipation. Moreover, by its special and constant composition this Water appears to me to merit a place by itself in the therapeutics of Mineral Waters."

Paris, 4th February, 1899

Dr. E. LANCEREAUX,

Professeur à la Faculté de Médecine, Paris; Médecin honoraire des Hôpitaux; Membre de l'Académie de Médecine.

"APENTA"

THE BEST NATURAL APERIENT WATER.

Sole Importers: THE APOLLINARIS COMPANY, Ltd., LONDON.

This remarkably fine Tonic Mineral Water issue the Island of Corsica. om a spring 1,968 feet above sea level at Orezza

It was known and used in France during the last century, but came prominently under the notice of the Medical Profession in that country in the year 1855 through a report published by the Academy of Medicine of Paris of an analysis by a renowned Professor of Chemistry, Dr. Poggiale, confirmed by Mons. Ossian Henri.

Since then the water has been extensively used in France and her Colonies and in Egypt and South America, as well as in Spain and other European countries, and is considered to be the best of all Mineral Waters in cases of Ansmia, Chlorosis, Leucorrhosa, and all diseases arising from impoverishment of the blood, and has been found of the utmost value in Gastralgia, Dyspepsia, and affections of the Liver and Spleen caused by residence in tropical climates, and in Debility after long illness, and in Intermittent Fever.

It is certified to contain:—

IRON, Carbonate and Protoxide.

MAGNESIUM, Carbonate.

POTASSIUM, Chloride.

SODIUM, Chloride.

Traces of Manganese and Arsenious Acid, and has sufficient "free" Carbonic Acid to cause it to effervesce on being poured into a tumbler.

It is the most palatable and digestible of all strong ferruginous waters, and with the addition of a little Lime Juice or Lemon Syrup makes

It is the most palatable and digestible of all strong ferruginous waters, and with the addition of a little Lime Juice or Lemon Syrup makes a pleasant table beverage.

Wholesale Orders for France and her Colonies to be sent to: -3 RUE ROSSINI, PARIS.

And Orders for all other Countries to be sent to

JUDGE, 6 St. Helen's Place, MARK WHITWILL. SON &

Superior to Cod Liver Oil, Tincture of Iron, or Peptone

Hæmoglobinum concentratum et Glycerinum purissimum [English Patent, No. 12,504, A.D. 1894], agreeably flavoured.) Entirely free from Antiseptic Chemicals.

A BLOOD-FORMING TONIC, OF THE UTMOST VALUE in General Debility, Anæmia, Chiorosis, Neurasthenia, Rickets, Scrofula, Weak Heart, Wasting Diseases of Children, Chronic Catarrh of the Stomach and Bowels, Loss of Appetite, Slow Convaiescence after Fevers, and Over-Rapid Growth In Young Persons.

Kept in Stock by all Pharmaceutical Chemists. Price of Original 9-ounce Bottle 4s.

P. Dose for young Infants, Half a Tea-spoonful, or one Tea-spoonful, twice a day in Milk, of the proper Heat for Drinking. For Children, One or two Dessert-spoonfuls, either pure, or mixed with any convenient liquid. For Adults, One Table-spoonful twice a day before food, so as to secure the full benefit of its powerful appetising effect.

Digitized by Google

PHARMACEUTICAL SPECIALITIES.

A NEW intestinal Astringent containing 87 per cent. Tannin and 13 per cent. Hexamethylene Tetramin. A brown non-hygroscopic powder, insoluble in water weak acids, and alcohol, but dissolves slowly in diluted solution of soda and alkali. It passes through the stomach entirely unchanged, decomposition commencing only in the intestines.

THE active principle of the Thyroid Gland, combined with sugar of milk in such proportions that one part of Iodothyrine is equivalent to one part of the fresh gland. Iodothyrine contains an exactly known quantity of Iodine and always produces uniform results. Is permanent and not liable to decomposition. In this it is distinguished from all Thyroid preparations at present on the market.

THE new silver compound for the treatment of Gonorrhæa. Most strongly recommended as an antiseptic wound-healer, and as a general substitute for Nitrate of Silver. Contains 8 per cent. of silver; is easily soluble in hot or cold water; absolutely non-irritating, and possesses a better penetrating effect than any other silver preparation.

A perfect substitute for Iodoform. Odourless and non-toxic. Five
times lighter than iodoform. Nonirritating, and does not produce a rash.
Adheres closely to mucous surfaces. Of
great value in burns, its soothing and
antiseptic action rendering it specially
serviceable in such cases. A 3 per cent.
ointment is recommended.

TANNOPINE

(Hexamethylene Tetramin Tannin).

IODOTHYRINE

PROTARGOL

(Proteinate of Silver.)

EUROPHEN

(Isobutylorthocresoliodide).

HAS an excellent effect, without secondary phenomena, in all the various kinds of enteritis when given in doses of to 8 grains for children, and 16 grains, 2 to 4 times daily, for adults.

Has given especially good results in cases of tuberculous inflammation of the bowels, in cases of non-tuberculous, subacute, and chronic intestinal inflammation, and also in cases of typhoid.

Has been used with marked success in Myxœdema, Goitre, Cachexia, following extirpation of the Thyroid, Tetanus, Obesity, Aoromegaly, some skin diseases—such as Psoriasis and Eczema—and some forms of mental affections. The commencing dose is 5 grains daily, to be gradually increased, according to results obtained. Prepared also in Tablets, each containing 5 grains.

PROFESSOE NEISSEE declares that Protargol is the best, the safest, and the quickest remedy he has yet employed in the treatment of Gonorrhea. Protargol possesses high bacterioidal properties, and is therefore excellent for the treatment of wounds. Has been used with the greatest possible success in Ocular Therapeutics. The usual strength of the solution for injections is ½ to 2 per cent.

Put up in bougie form by Messrs. R. Sumner & Co., Lord Street, Liverpool, and R. Manson, 75, Fortess Road, London, N.W.

PRINCIPALLY useful in veneral diseases; in this direction it accomplishes more than any remedy hitherto tried. In cases of scrofulous, syphilitic, and varicose ulcerations a 5 per cent. ointment will befound most advantageous. May be used either pure or combined with equal parts of boric acid.

Trional, Tannigen, Salophen, Lycetol, Creosotal, Duotal, Heroin, Aristol, Tetronal, Analgen, Losophan, Somatose, Iron Somatose, Milk Somatose, Phenacetine-Bayer, Sulfonal-Bayer, Piperazine-Bayer, Salol-Bayer.

Samples and Literature may be had on application to the Wholesale Depot for all Bayer's Pharmaceutical Specialities.

BENGER'S

GOLD MEDAL AWARDED

Health Exhibition, London.

FOR INFANTS, INVALIDS, AND THE AGED.

 \mathbf{FOOD} .

This delicious highly nutritive and most easily digested Food is specially prepared for Infants, and for those whose digestive powers have been weakened by illness or age.

The following letter addressed to F. B. BENGER & CO., Ltd., is published by special nermission of the Russian Court.

"Balmoral Castle,

"Scotland, 25th Sept., 1896.

"Sirs,—Please forward to Balmoral Castle one dozen 2/6 Tins of BENGER'S FOOD for H.I.M. THE EMPRESS OF RUSSIA, addressed to Miss Coster. We have received the box ordered from Peterhoff.

"Yours truly, F. COSTER."

BENGER'S FOOD is sold in Tins at 1/6, 2/6, and 5/-, by Chemists, &c., everywhere.

Wholesale of all Wholesale Houses and Shippers, or of the Manufacturers,

F. B. BENGER & CO., Ltd., Otter Works, Manchester.

TELEGRAPHIC ADDRESS: "Benger's, Manchester."

Digitized by Google

The Lancet describes it as "Mr. Benger's admirable preparation."

THE MEDICAL PRESS says:—"Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick."

The British Medical Journal says:—"Benger's Food has by its excellence established a reputation of its own."

The Illustrated Medical News says:—"Infants do remarkably well on it. There is certainly a great future before it."

A Government Medical Officer writes:—"I began using your Food when my son was only a fortnight old, and now (five months) he is as fine a boy as you could wish to see."

From an eminent Surgeon:—" After a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed."

A Lady writes:—"Really I consider that, humanly speaking, Benger's Food entirely saved baby's life. I had tried four other well-known Foods, but he could digest nothing until we began the Benger.' He is now rosy and fattening rapidly."

THE TERM "CONSERVATIVE SURGERY"

AS IT HAS BEEN PROPOSED TO APPLY
IF TO THE UTERUS AND ITS

APPENDAGES.

By LAWSON TAIT, F.R.C.S.Eng., &c.,

Late President of Masons College, and Professor of Gynsecology.

I was very much amused some months ago by an article in the Nineteenth Century on Anæsthetics, in which it was recommended to the laity that each one of us should "refuse resolutely to take chloroform or allow any member of our family to take it without first obtaining a guarantee from the anæsthetist that he will administer it on an open cloth held at a given distance from the nose, and that the time taken to put us under shall not be less than eight minutes." I was amused because the Nineteenth Century is published in London, the very hot-bed of new anæsthetics and new methods of administering them. was amused because here was Simpson, of 1851, coming back after nearly fifty years and his method being forced back on the medical profession through a lay journal—an offence of the direct description The offence was resented, of course, by a large number of medical journals in this country, on the Continent, and in America, and, of course, the greatest amount of fun was to be had out of the criticism and opposition of our trans-Atlantic friends. One of the most prominent, and I think the best of the American medical weeklies had a leading article on the subject in which the very difficult task was fully accomplished of admitting the need and justice of the outery on the part of the patients as voiced by the Nineteenth Century. "The fault in this country," says the article, "is for the most part limited to the administration of ether, where the most inexcusable indifference to the patient's comfort is often demonstrated. The man who gives the anæsthetic in a hospital is regularly the youngest man on the staff, a fresh graduate with theoretic teachings alone, or the example of another intern as his guide. The cone soaked with ether is crowded down over the patient's face, and he makes a courageous effort to stand it for a time. Very soon, however, he struggles to save himself from what these patients afterwards describe as a feeling of imminent suffocation and death, and gains a breath of fresh air only in those cases when the orderly or orderlies are unable to hold him down." It may be a little comfort that they are as bad in America in one way as we are here in another, but the whole thing is discreditable to our profession, and absolutely subversive of any claim ever to rank as a science For here we have the greatest drug ever introduced, imperatively the greatest boon ever granted to humanity after opium, that is an ideal anæsthetic to my mind of course chloroform; and we are not yet agreed about it, its method of administration, its power and its method of fatality: in fact, we are agreed only that it is an anaesthetic. The history of this magnificent subject during the half century is a record of proceedings not only entirely unscientific, but eminently discreditable to a body of men who are supposed to have, by their examination in Euclid's six books, to have at least mastered the elements of the art and science of logic. It is a history of rash and unjustifiable introductions of new substances and new methods, going as far as the introduction of the old substance under a new name, "a substance much safer, more rapid, more and everything better than chloroform" by a man who was for a time a medical Cagliostro. We had, of course, hundreds of courses of experiments on animals, in India and elsewhere, with conclusions as absolutely hostile as well could be. We have had initiated only one logical research in the shape of the "Anæsthetic Committee," inaugurated by our own Association which still dawdles its slow length along and will report, as I am informed, about the year 1950.

If I had time I could illustrate my purpose as well in the matter of new drugs, but I shall content myself with one short quotation concerning one of the newly passing foibles, "Thyroid" and its use in bleeding fibroids. In the Medical News (Phil.) p. 17, Moseley reports "That while some patients can take comparatively large doses of thyroid with impunity, others are injuriously affected by small amounts" and having established this extraordinary conclusion concerning our cherished sweet-bread, he tells us that they have a marked influence in bleeding fibroids, in checking the excessive loss of blood, and in some cases in diminishing the size of the growth. His observations were extended over five cases, and is an example of the sort of thing which almost renders our desire to see new drugs kept out of the market by Act of Parliament till they had passed through mill of judicious and stipendary investigation.

The fault of this logical deficiency is not, of course, confined to affairs medical, for we find the general affairs of the whole nation ruled, say at a General Election, by the words and votes of the floating residuum of voters in the least important, and generally therefore the most incompetent electoral country, and we seem now to be on the threshold of a vast upheaval within the serene demense of our National Church, the result of a ruthless spirit of innovation and desire for new methods and new manners, not even a revival of the good old things so faithfully followed by our ancestors for over a thousand years.

But in matters medical we ought to do better than that, particularly is it possible in matters of surgery when we have proof of results not tangible in the sister art of medicine, save within very limited lines.

For the last forty years, I think, hardly an inaugural address dealing with the generalities of the advances of surgery has omitted reference to the history of ovariotomy as one of its crowning glories. But I do not accept the story in that way at all. I think the whole thing discreditable, and for one reason only, even if no others were available, that whereas Nathan Smith penetrated the secret to the very depth, and published it in 1827, his great discovery was pushed aside by "new methods," and the great advantage of it was withheld from suffering humanity for more than half a century. Surgical

historians, writing towards the end of the coming century, will not look on this as a brilliant record.

Arrived at the year 1878 we put the removals of ovarian tumours down with a mortality of 5 per cent., and then paused to look round. The start of abdominal surgery from this point was made when I showed that 100 consecutive exploratory incisions could be done with a hardly appreciable mortality, and then I formulated and established the law that when conditions in the abdomen threatened life or made it unbearable, we were justified in opening the abdomen to discover the site and nature of the disease. Out of this, as a matter of course, arose one by one and rapidly, as my records show, all the modern and fully accepted operations for gall-stone, &c., which now fill large text-books. Among these records fully numerous operations on the uterus and its appendages, most of which have become classic and will remain so, unless upset for a time by men merely restless and new methods wholly unnecessary.

It is needless to say that in this long battle, going over now a period, so far as I am concerned, of more than thirty years, I have not, I did not consider it necessary, and it certainly would not have been advisable to make public every step in the process. Mistakes were made, methods employed were found to be faulty and unsuccessful, and nothing would have been gained by dilating upon them or even drawing attention to them. Just as I started, Dieulafoy had introduced his aspirator—an instrument in the device of which he had been anticipated by Bowditch and Protheroe Smith; indeed, by many others, until we get back to the Roman surgery of Pompeii; and Maisonneuve had fought the battle of the drainage tube. The pelvis did not escape either of those proceedings, and they were fully employed. Between 1871 and 1878 my carriage bag always had an aspirator, but for at least twelve years I have not used it. With it I carried a number of ingenious devices for making openings in the vagina, and get-ting drainage tubes into something, never knowing exactly what, sometimes curing, but more often failing to do real permanent good. But as it dawned on me that the peritoneum had no real terrors if respectfully treated, I found that it was better to ascertain accurately what was needed by careful ante-mortem examination, rather than make hap-hazard shots from below, and after a series of trials came my paper on "Treatment of Pelvic Suppuration by Abdominal Sutures," which revolutionised the practice of pelvic surgery all over the world. Not only so, but it cleared up the pathology of the pelvis and put a stop to the eternal and ignorant wrangling about perimetritis and parametritis which had gone on for nearly thirty years. Of this, of course, the present generation has no need to know anything, and truly it does not as may be seen from the contents of a paper by Dr. Noble in seen from the contents of a paper by Dr. Noble in the *Philadelphia Medical Journal* of July last, entitled the "Conservative Treatment of Pelvic Suppuration of Puerperal Origin." He begins, as is not unusual with such people, by references to, and conclusions derived, according to his interpretation from my own writings, and succeeds, as is equally usual, in completely distorting my teaching. He goes so far as to quote my own words almost verbatim, and then commenting on them in this sentence: "These elementary pathological facts are now generally recognised, although some years ago they were sharply controverted, more especially by the disciples of Tait."

According to his contention the truth was first established by the publication of four cases of "True Pelvic Abscess," by Dr. Charles P. Noble, in August, 1891, before English gynæcology was born. He gives his idea of the differential diagnosis between pelvic cellulitis and pus-tubes or intraperitoneal abscess (regarding these two as the same) and misses the funda-

mental parts of my teaching on this subject first published ten year before his paper of 1891, that there are two varieties of intraligamentous suppuration, one in the outer half of the layers, which he has recognised and another in the inner half, quite as easy to recognise, found in the left side, having a sign which there is no mistaking, and then he goes on to describe such a case which he did not diagnose, but mistook when he need not have done; for which he opened the abdomen correctly enough but did not proceed to complete the operation as he should have done. Subsequently he attacked the abscess from the vagina, as he might have done at first if he had been at all familiar with my teaching, or had been one of those disciples upon whom he pours the vials of his contempt.

It is not for such blundering as this that I now draw attention to Dr. Noble, but because he is an example, though a very bad one, of the clouding school of abdominal surgery. Of these most exist in Germany, and the movement seems to be reaching England, and whilst I would be the last, by my utmost endeavour to deride change merely because it was new, I deprecate change when introduced for no other purpose than its novelty when its novelty leads us off the track of the investigation of facts already quite familiar to us, but concerning which we

have not arrived at final conclusions. That suppuration in the pelvis should not be made the subject of surgical rule different from that affecting other regions had to be my cry for nearly ten years, or as I put it that a surgical writ shall run in the pelvis as it does in the knee joint, and I carried my point against all comers. The chief carried my point against all comers. opposition was, of course, from the uterine tinkerers who were overwhelmed by seeing their consultingrooms emptied of the helpless sufferers, who came day after day for a glycerine plug, or month after month for new pessaries. They raised the cry of "spaying women," "emasculation of women" (a strange mixture of etymological definition), and even went so far as to say that we surgeons operated for the fees at the end of the cases. This cry ceased, however, when it was shown that the operating table of the surgeon was much cheaper in the long run than the consulting-room of the pessary-monger; and, personally, I am now in a position to say that I should have been a much richer man if I had never seen any of these cases, for as I had to give bed room to the great bulk of them I was out of pocket, and largely, y the whole transaction. The strange thing is that the cry is still kept up by beardless boys who tell us what they can have no personal knowledge of, whether it be true or not, "that the reckless way in which, in the past, gynæcologists have removed uterine appendages without adequate justification, is the opprobrium of our art." In the past I was in the habit of checking such nonsense by saying that such intormers either knew of such proceeding or they did not. If they did not they were liars. If they did it was their business to give such information as would put the offenders on their trial for felony; and failing to give such information, they were themselves accessories after the fact, and so liable to indictment. I went so far as to serve notice on a well-known London physician who was guilty of this that I should prosecute him if he did it again, and since that time he has been quiet.

Another parrot cry still being repeated was that most operations made the patients absolutely sterile. But then they were so rendered by the disease before our operation. Disease of the knee-joint makes a man lame, amputation of the limb confirms the lameness, and the best case of a "conservative" result of an excised knee-joint I have ever seen did not get about free from lameness—in fact, I think the lame-

ness was worse than it would have been with a firstclass artificial limb. Double pyosalpinx renders a woman absolutely sterile. Nay more, as a rule she cannot have intercourse. Removal of the appendages does neither increase nor decrease the sterility, and it often removes completely and permanently a grave interference with marital life. Opening and draining a double pyosalpinx may do as much, but that it will cure sterility-pigs may fly, but I have yet to see a flight of them.

Foiled in all such arguments, our critics have found another platform, and I take again Dr. Noble as my example; he is as good for my purpose as any other of the score from which I might select, they are all as deficient in logical acumen as he is, they put their cases quite as badly, and they are all as open to the same suspicion of quackery, there is no use mincing terms or using plausible phrases to hide the

pill which must be swallowed.

It is forgotten, or, at least, seldom acknowledged by gynæcologists, that the adoption of measures does not rest with them, but with the mess of the profession, men in general practice, upon whom rests the responsibility of advising their patients for what seems to be the best. It is perfectly true that the profession will be and must always be governed by the weight of a great name, so that I had a very hard fight after the International Congress at London in 1881, when Spencer Wells said that he had only once seen such a case as I described in his life. I answered by publishing a long series of my own cases which had been previously under his own care. This cost me his personal friendship, a result I regretted as long as he lived, and still regret, but I won the I silenced Mathews Duncan by compelling him, almost by threats, to come with me to a neighbouring house in London, to see me remove two huge bags of pus in a patient under the care of Dr. Chapman Grigg, which had quite recently been under that of Dr. Duncan. I met the personal difficulty with another case in London, when six distinguished practitioners met me and assured themselves that I had exaggerated my diagnosis, that there was nothing much the matter, by taking Keith to London, making him operate, and then submitting to them his written report of the operation.

Now another battle rages, and I shall halt no more in it than I did in the former, though my fighting powers are no longer as sharp as they were, nor my taste for warfare as great. We are told once more, though the contrary has been proved over and over again, that in a considerable majority of cases there is diminution or total abolition of the sexual instincts This is not true, in fact it is absolutely untrue. It is a subject on which, of course, the publication of facts is extremely difficult, either one way or the other. But my own facts establish the conclusion that the cases of abolition are extremely few, not more than 5 per cent, but they get greatly tattled about by loose-minded women and by men whose sense of honour and proper reticence in matters concerning their wives is strangely defective. On the other hand, the instances of restitution of marital relations, which had been entirely destroyed by disease and restored by the operation required are at least 60 per cent. of all the cases. In a few instances the mysterious fact remains that women who before operation had little or no sexual appetite have it developed after treatment to an extent which becomes inconvenient. I removed the appendages, twelve years ago, of a lady noted in public estimation to the highest degree. She had had one child, and her husband had never shown any sexual response whatever, till after the operation, when it became oppressive to him and he died. She lived as a widow for three years,

of the uterus, and this I carried out, not only without benefit, but rather with an increase of the trouble. She greatly objected to the idea of a second marriage. and had always resented my advice and the advice of her parents, in that direction; but at last, and entirely to save her conscience from the reproach of wrong, she married again, and a few months ago the fact was announced in every paper in Europe. It is, therefore, perfectly useless to say that in a few cases the sexual tastes are destroyed. What kind of an argument it is, I shall consider afterwards, but meantime I go on discussing it on what merits it has, to prove the argument, and put in semi-decent form. the word "conservative" is introduced, a piece of

rampant deceit and chicanery.

Dr. Noble has two papers that I have already quoted, and another on "The Conservative Treatment of Fibroid Tumours by Myomectomy." The paper is hardly worth referring to, reeking as it does of all the work of Simpson, Penn, Marion Sims and others of less note, who brought myomectomy as far as it would go, more than a quarter of a century ago, and there it was left by all of us. But the paper is a useful warning of a common logical error, the use of the indistributed middle term, or in plain words, the use of a term devoid of definition and employed with various and irreconcileable meanings in the course of the same argument. Thus in the one paper he alludes to the preservation of parts of ovaries diseased and adherent, and bits of occluded tubes as "conservative surgery," whilst in the other the same thing means removal of the whole uterus, the absurdly so-called pan-hysterectomy, revived from the moral of Pean's "Morcellement," and hashed up

as something new.

The term "conservative surgery" was introduced by Ferguson in the late "fifties," and was the cause of a hot feud between him and the more logically-minded Syme. But, as Ferguson puts it, it was fair enough, and became afterwards limited almost entirely to its best example, that of excision of the knee-joint. Ferguson was a prince of operating surgeons, and none who can remember his magnificent figure and wondrous features, unmoved as he made the knife fly, as things in the old days, with a rapidity which few eyes could adequately follow, can easily believed that such an operation as excision of the knee-joint would meet with his strong approval. In theory it was all right. Conserve the lower limb; it must always be better than an arti-But, alas! though his pupils carried the ficial one. banner of this conservatism far and wide, it did not keep its promise, and on Syme's face there was to be seen, and then only, that strange little smile of triumph as he lopped off a "conserved leg." "Con-serve the parts," was his only comment, and the operation took a back seat, and occupies now a very restricted area.

Fancy my astonishment, therefore, when I read in the second paragraph of Dr. Noble's second paper this sentence:—"In the recent past true conservatism -that is, the welfare of the patient-has required," &c. This is another theory, and completely confirms my lifelong belief in politics that the advanced Liberal is the truest Conservative. Certainly, with this definition, we all are, all hope to be, all must strive to be, truly conservative. But why should Dr. Noble pretend to be that and exclude others equally earnest in their efforts, and why should he use for himself a phrase which reminds one of the story of the two men who went up into the temple to pray. If he claims exclusively to be a Conservative, then I say he is also a Pharisee, as are also those who use this phrase as he uses it.

For what is its real intention, other than to declare applying to me from time to time for arrest of this that he has, and uses, a method of operating which symptom, until it got so bad that I advised removal conserves the sexual instinct, as he plainly does in his concluding sentence, together with a hope that the sterility may not be complete, nor completed.

In all such cases the probability of the restoration of fertility is so minute in these cases that it is wholly unworthy of discussion or acceptance, save in some very unusual set of conditions, as when the succession to a crown is concerned, and then I, for one, would not accept the responsibility. Crowned persons are a rule unto themselves, and I never cared to share in the government. For the general public the terrible facts of over population, and the fact that of all children born one half die before they are five years was enough to dismiss such a bagatelle from my mind. When such patients have been married for years and remained sterile, it may be assumed that the sterility is complete, and when the mischief has resulted after the birth of one or more children the patients themselves usually dismiss the argument with impatience. The second question, I find, is now being directed towards the apprehension of the husband more than to his partner, and here is where the quackery comes in.

In a recent case where I was concerned, and where it was strongly wished that the case should be got out of my hands, it was urged that where on the one hand I would geld his wife and make her like a log of wood, another surgeon who was strongly recommended as of the Conservative school, would leave her active, the husband promptly replied that the case was that of his wife not that of a strumpet, and the efforts failed. I confess that this is how I should look at the question, especially in the light of the published experience of Laudson and others who are practically the leaders of this new movement, aided by what is probably of far more importance, my own wish and longerestablished experience. The whole thing is based on a misconception of the function of the ovaries, which have no more to do with the sexual appetite than the kidneys. Nor have the Fallopian tubes, nor the uterus; as it is maintained, and as I have proved, sometimes increased by the complete absence of all five. The two most erotic women I have ever come across were two sisters in whom not the slightest trace of uterus or ovaries could be determined, and in one of them I had positive knowledge of the fact of that complete absence when I operated upon her for tuberculous peritonitis. They were in good social position, were not insane, yet no kind of inducement, social, parental or restrictive could prevail upon these women to refrain from inspiring every man with whom they could get an opportunity to have inter-course with them, and faute de mieux, they were confirmed Sapphists.

Finally is it an argument, even if it could be sustained, which we, as surgeons, can give weight to?

I do not often quote Scripture, but I think that a great clinical lesson on this subject may be got in the 5th Chapter of Matthew, when at the 29th verse we are told that "if thy right eye offend thee, pluck it out, and cast it from thee. And if thy right hand offend thee, cut it off and cast it from thee; for it is profitable for thee that one of thy members should perish, and not that thy whole body should be" infected with bacilli, a lesson which is still more emphatically localised as pertinent to the present man by my national poet in words which read-

> "Geld you, quo he, and what for no? If that your right hand, leg or toe, Should ever prove your spiritual foe You should remember To cut it off-and what for no Your dearest member?"

We are not called upon to play the part of moralists,

have always held in detestation any surgical proceeding which brings with it a risk that the patient shall have to submit to a second operation. therefore, always steadily opposed all operations for malignant disease undoubtedly pronounced. Nothing brings so much discredit on our art, nothing so much discredits the individual practitioner. Not only so, but second operations in the pelvis are always more difficult than the first, and according to all published facts far more fatal than operations completed at first. So much is this the case that I have been driven by the stern logic of facts to advise a more complete operation than ever in certain kinds of disease of the appendages. I refer to those in very young women, when the mischief has arisen apparently at, or even before, the molimenal period. I am certain that of all the cases of suffering from the results of chronic inflammation of the uterine appendages they suffer the most, their sufferings begin soconest, and they are the most difficult to relieve. Among them I have had my worst and most bitter disappointments of relief expected, and have had discredit in this class of cases. About eight years ago I removed the uterus in one young lady, from whom I had removed the appendages thirteen years before, not only with a failure as result, but I had made her worse; she had taken to drinking, been placed in an asylum, and had altogether gone to the bad. I removed her uterus and cured her promptly and, after nearly eight years' success, I think I may say permanently. I followed this case up, and hunted up a number of my known failures, removed the uterus in eleven more cases, and have succeeded in all, and I am now hunting up some more. This is conservative surgery. As a cross to it, I was called to London a few weeks ago to a consultation with one of the eminent West-end doctors in a case of this kind. I advised a complete removal, but the patient was conservative in the other way. She was surethat it was all in the right ovary, and the right ovary alone was to be removed. After much arguing and a full understanding in black and white, I consented to divide the operation, and removed the right ovary and tube. We shall see. do not usually accept a fettered condition such as this, but my colleague is a man for whom I have a great reverence, and he took the responsibility; therefore, I acquiesced.

My belief is consummate in such radical surgery as will preserve my patients from further risk, and I do not regard the "sexual appetite argument" as worthy of any but the brothel-keeper, with whom it would, of course, have great weight. Concerning the surgical difficulties and dangers of the so-called "conservative" operation, my old experience of the early "seventies" are confirmed in a paper by Mr. Stanmore Bishop, in the MEDICAL PRESS AND CIRCULAR for November 23rd, 1898, and I need do no more than refer to that common-sense contribution to the subject.

ADENOMA UNIVERSALE OF THE **ENDOMETRIUM**

THE MYOMETRIUM IN INFILTRATING VIRGIN, FORMING AN ABDOMINAL TUMOUR -PAN-HYSTERECTOMY-RECOVERY.

By JAMES OLIVER, M.D., F.R.S.Ed., F.L.S., Physician to the Hospital for Women, London.

THE patient who is the subject of this annotation is a virgin. She came under my care in the first but this we are called upon to do, to adopt as our guiding principle to do the best we can for our 34 years of age. Menstruation was not established patients and for our art, and then for ourselves. I (until she was 18, and during the four succeeding

years, i.e., until the patient was 22, the menstrual discharge appears to have been moderate in amount. It thereafter became more profuse, and during the last ten years it has on several occasions (about twelve in all) been extremely abundant. The menstrual period preceding her visit to me had been a profuse one and had lasted six weeks and she was very anæmic in consequence. She had never experienced pain in association with menstruation. The following are the physical signs which were noted in November, 1895. The hypogastrium is occupied by a small globular and regular swelling which arises from the pelvis and extends to two and a half inches above the pubes. It is uniformly firm in consistence. The hymen is intact. Hanging from the cervix uteri are two mucous polypi of about the size of small hazel nuts. The hypogastric tumour is the uterus enlarged. On this occasion I merely removed the polypi. The patient thereafter enjoyed fairly good health, losing occasionally rather freely until October, 1897, when she consulted me because she had been losing continuously for eight weeks. The physical signs then noted were the following. The hypogastric tumour is slightly larger than it was in November, 1895, and its consistence is hard. Hanging from the cervix uteri is a mucous polypus of about the size of a large hazel nut. I now advised not only that the polypus should be removed, but that the uterus should be dilated and explored. By means of a somewhat sharp spoon I removed on this occasion from the cavity of the uterus nearly a teacupful of material which when examined under the microscope presented the appearance of a simple adenoma. The size of the uterus was thus so greatly reduced that it could not be detected abdominally. About two months after this operation patient began to complain of a watery discharge from the vagina, and in consequence of this troublesome symptom which necessitated in May, 1898, the use of three and four diapers a day, she again came under my care. I then found that the hypogastric tumour had reappeared, and that the uterus was of about the same size as it was prior to the last operation. Before submitting the patient to hysterectomy I decided to curette freely the endometrium once more, and this I did, removing again about a teacupful of adenoid material. The watery discharge reappeared soon after this operation, and as it became more and more distressing the patient sought my advice again in October after an interval of only five months. The hypogastric tumour had now re-appeared, and was as big as it had ever been. I now advised, and performed, the operation of pan-hysterectomy, removing the whole uterus by the abdominal way. The broad ligament on each side was secured by three ligatures of silk. The lower ligature only on each side, namely, that including the uterine artery was pulled down into the vaginal canal and was left long; the other ligatures were cut short. With fine silk the peritoneum at the top of the bladder was stitched to the peritoneum, which had entered into the formation of Douglas's pouch, and thus the peritoneal cavity was shut off from the vaginal canal. The patient made an excellent recovery, and was able to

go to the seaside after the operation.

The uterus weighed twenty-eight ounces, and was equal in size to that containing a three months' fœtus. On opening the organ anteriorly by a triangular flap, reflected from the cervix towards the fundus, the endometrium (corporeal and cervical) showed myriads of smooth prominences varying in size from that of a split pea to a walnut. Most of these new growths were practically sessile but a few were polypoid. The muscular tissue of the organ generally was much thickened, and to the naked eye even it was apparent that the new growth had infiltrated extensively this structure. Sections of the smooth pro-

minences and of the underlying muscular tissue display under the microscope the appearances characteristic of adenomata, namely, tubes lined with cylindrical epithelium.

On account of the manner in which the neoplasm invades the muscular tissue of the organ, pathologists will affirm that the disease is malignant. In attempting, however, to settle this important question we cannot accept the tenets of the pathologist alone and discard altogether the clinical facts. In November, 1895, when the patient in the first instance came under my care, the enlarged uterus formed a hypogastric tumour which was then almost, if not quite as large as it ever was on any subsequent occasion. period the muscular tissue was already extensively infiltrated by the new growth, as the consistence of the uterine tumour was on this occasion as firm as it was at the time the operation of pan-hysterectomy was performed. It is impossible for us to surmise how long the hypogastric tumour may have existed before the patient came under my care; as, however, it increased but little in size between November, 1895, and October, 1897—a period of nearly two years—it is more than probable that it had been in existence, and had maintained a more or less stationary state, for several years. It is quite evident that the disease must have progressed slowly. as the prolonged and excessive hæmorrhage, which occurred when the patient was as yet only 24 years of age, was undoubtedly due to the neoplasm having already attacked the endometrium. With a clinical history, such as we have here presented, one would hesitate to characterise the disease as malignant. In the case which I have just recorded the specimen is an unique one, and the patient is probably the youngest that has ever been reported with adenomatous disease of the endometrium of so extensive a character.

It is an interesting fact that the lining of the cornua uteri in horned ruminants shows smooth prominences devoid, however, of utricular pores. They are called "caruncles" or "cotyledonal processes," and they increase in number with the size of the species. In the giraffe as many as eighty of these processes may be detected. In the bison they are softer, thicker, and more obtuse than in the giraffe, and they are less regularly disposed than in the latter animal. They are also very pronounced in the uterine cornua of the goat and sheep. When gestation occurs in animals possessing these cotyledonal processes their surfaces which previously were smooth become sometwhat papillose, and into the depressions thus formed the chorionic villi are thrust, and are there retained until parturition takes place. At birth the fœtal villi are withdrawn from the maternal processes, and soon afterwards the surfaces of the latter become again smooth. Occasionally the entire caruncle is shed after parturition, and when this happens it is never reproduced.

never reproduced.

Prof. Mettam, of the Royal Veterinary College, Edinburgh, informs me that the cotyledons in horned ruminants are upheavals of the mucous membrane, contain a good deal of corium and are very vascular. They are covered by the ordinary epithelelium.

Now, the disease which I have just described as occurring in the human female is an overgrowth of the lining membrane of the uterus, and we may perhaps be justified in believing that it is the revelation of a "reversion to type" tendency.

THE magistrates at St. Albans have decided that bread is meat. A man had been prosecuted under the Poisonous Meat Act for having thrown some poisoned bread to his neighbour's hens. He was accordingly convicted.

ON THE PREVALENCE OF TUBERCU-LOSIS IN IRELAND AND THE MEASURES NECESSARY FOR ITS PREVENTION. (a)

By THOMAS W. GRIMSHAW,

President of the Medical Section of the Royal Academy of Medicine of Ireland, Vice-President of the Statistical Soc. of Ire. &c.

AFTER some introductory remarks the author proceeded to analyse the principal statistics of tuberculosis, and especially of phthisis mortality in Ireland, the analysis being mainly founded on a table of the deaths from tuberculosis in children under 5 years of age, and of phthisis at the various ages of active life from 15 to 45, in town and country districts. The result of this analysis showed the following remarkable results:—During the three years dealt with in the table, 1895, 1896 and 1897, the average annual death-rate from all causes for Ireland was 173 per 1,000; the rate for the town districts (that is towns with a population of 10,000, and upwards) was 254, and for the rest of Ireland 152. For Ireland the death-rate from all tuberculous diseases, exclusive of phthisis, was 0.7 per 1,000 for country districts 0.4, for town districts 1.5 or nearly four times the latter rate. For consumption alone the rates were for Ireland 2.0, for country districts 1.7, for town districts 3.3, or nearly double the usual rate. Taking all forms of tuberculous disease, the rate for Ireland was 2.7—for country districts the rate was 2.1, for town districts 4.8, or more than double. In the districts with six large towns the rates were—from all causes 26.2, as compared with 15.2 in country districts; from tuberculosis other than phthisis 1.6, against 0.4, or exactly four times the rate; for phthisis 3.5, against 1.7, or elightly more than double the rate; and for all forms of tuberculosis combined 5.1 against 2.1, or considerably more than double as compared with country districts. It will be observed that by far the most important cause of death dealt with in the foregoing remarks is phthisis. This disease alone caused 11.7 per cent. of all the deaths in Ireland during the period under consideration, the percentage for the districts with towns of over 20,000 population being 13.3, for those with towns of 10,000 inhabitants and upwards 13.2, or slightly less, as compared with 11.1 per cent. for the rest of These figures point to a conclusion which to many will be somewhat unexpected, namely, that the proportion of deaths from consumption to total deaths is very high even in the country districts of Ireland. If we compare the death-rate from tuberculous disease in the six great town districts of Ireland as measured by the general population we find that of the forms of tuberculosis other than phthisis—Dublin and Belfast are the same, 1.8 per 1,000; Londonderry next, 1.6; Waterford 1.2; Cork 1.1; and Limerick 0.7 only. In the case of phthisis we find Belfast leads with a rate of 3.9, Cork follows with 3.8, then in order Dublin 3.3, Waterford 3.2, Limerick, 3.0, Londonderry 2.5. These figures are sufficiently serious, but when we consider the question of the ages at which tuberculous diseases are most fatal we find still more alarming results. In the case of death-rates there may be some errors owing to unestimated variations in population since the last Census, but when we consider the rates of deaths from tuberculosis to those from all causes of death this element of doubt has little or no significance. I shall first deal with the question of tuberculosis as its affects young children—by this I mean children under five years of age. It has been shown by Sir Richard Thorne, and

(a) Abstract of paper read before the meeting of the Academy of Medicine of Ireland (Section of State Medicine), Feb. 17th, 1899.

by the report of the British Medical Association, that the tendency to the disease of tuberculosis among young children in England and Wales is not so marked as it is in the case of phthisis. The forms of tuberculosis which kill young children are tabes mesenterica, tuberculous meningitis, and forms of tubercle other than pulmonary consumption. We find that in Ireland the death rate of children under 5 years of age from these forms of tuberculosis was 3.5 per 1,000 living at this age period. In the districts with towns of 10,000 and upwards the rate was 8.7 as compared with 2.0 in country districts, or more than four times the rate. In the six large towns taken collectively it rises to 94. in Dublin it reaches 11.0, and in Belfast 10.0. In the other it is considerably below the 10,000 town's rate, the rate for Limerick being only 3.3, or less than the average rate for Ireland. The very high proportion of deaths in Dubliu and Belfast is very remarkable and very serious. If we now pass to the more active periods of life, and consider the deaths from tuberculosis between the ages of 15 and 45, the main working periods of life, we find that in Ireland during these age periods the death-rate from tuberculosis of all kinds was 3.8 per 1,000 living at these ages (out of a total rate of 7.9 from all causes, being nearly one half), of which the phthisis rate was 35. In the towns of 10,000 and upwards the rate was 5.5 out of a total rate of 12.2, of which the phthisis rate was 5.1. In the six large towns the rate was 5.7 out of a total rate of 12.6, phthisis having a rate of 5.3 It will be observed in the foregoing statement the death-rate from phthisis dominates the whole series of figures, and therefore we may confine our attention in detail to the proportion of deaths from that form of tuberculous disease, and here I shall deal only with the proportion of deaths from phthisis to the total number of deaths, as showing in the clearest manner the immense amount of damage done by phthisis at the most active periods of life in Ireland. At all the age periods from 15 to 45, except that between 35 and 45 the proportion of deaths from phthisis to total deaths in the country districts exceeds that in the town dis-tricts (of populations of 10,000 and upwards) when taken collectively, and that this is also true of the towns with a population of 20,000 and upwards when compared with the country districts. Taking Ireland as a whole we find that during the whole age period of 15 to 45 the deaths from phthisi constituted 43 5 per cent., in the period from 15 to 35, 49 6 per cent., or nearly one-half, in that from 15 to 25—which is apparently the most fatal age period - 528 per cent., or more than one-half, from 25 to 35, 461 per cent., and from 35 to 45, 29 1 per cent., compared with a total for all ages of 11.7 per cent. of the total deaths. It is important to emphasise the fact that the age at which phthisis causes the greatest proportion of the total mortality in Ireland is during the age period of 15 to 25, and to point out that the percentage of deaths to total deaths during this period reaches the terrible total of 44.6 per cent. in Dublin, 55.4 per cent. in Belfast, 54.4 per cent. in Cork, 56.3 per cent. in Limerick, 52.5 per cent. in Londonderry, and no less than 58.6 per cent. in Waterford. In the next decade of life, 25 to 35, the percentages fall somewhat in each case, but are still so near one half of all the deaths at that age as to excite considerable alarm as to the ultimate result to what ought to be the most active portion of the community. I would again point out that this table is founded on the most recent information available at the present time. Dr. Grimshaw then proceeded to point to the remedies and mainly relied on those put forward in the report of the Tuberculosis Committee of the British Medical Association, and quoted with approval the recom-mendations of the last Royal Commission on Tuberculosis.

The Coulstonian Lectures

ON THE

PATHOLOGY OF THE THYROID GLAND.

Abstract of Lecture I, delivered before the Royal College of Physicians of London.

By GEORGE R. MURRAY, M.A., M.D.Camb., F.R.C.P.,

Heath Professor of Comparative Pathology in the University of Durham; Physician to the Royal Infirmary, Newcastle-upon-Tyne.

THE embryology and comparative anatomy of the thyroid gland furnish us with important information as to the origin of its present situation, structure, and function in man. The fully-developed gland consists of three parts, two lateral lobes and the isthmus which unites them. The two lobes are closely applied to the sides of the larynx and trachea, and extend backwards as far as the sides of the pharynx and esophagus. At the level of the isthmus the recurrent laryngeal nerve lies in the angle between the esophagus and the trachea, being covered externally by the lateral lobe of the gland on each side. In front the gland is covered by the sterno-hyoid, sterno-thyroid, and omo-hyoid muscles. Laterally the lobes extend outwards in front of the common carotid arteries. Each lateral lobe is shaped somewhat like an almond, but the upper end is narrower and more pointed than the lower. The lower end lies on the fifth or sixth ring of the trachea, while the upper is generally on a level with the middle of the thyroid cartilage. The position of the isthmus varies, but it generally lies in front of the second, third, and fourth rings of the trachea. In many cases, variously estimated at from 40 to 68 per cent., the pyramid or middle lobe extends as a thin process from the isthmus or from a neighbouring part of one of the lateral lobes up to the hyoid bone, to which it is attached by muscular or fibrous tissue. The gland is firmly fixed to the larynx and trachea by fibrous tissue, so that it follows the movements of these structures which take place during deglutition. The gland when freshly removed is of a dark brown-red colour. It usually weighs from an ounce to an ounce-and-a-half (30 to 50 grams). It is relatively larger in the infant than in the adult. The whole gland, however, is liable to considerable variations in structure, such as inequality in size between the two lobes, absence of one lobe, and absence or irregularity of the isthmus.

There is a rich blood supply from four arteries, the superior and inferior thyroid arteries on each side, and in

superior and inferior thyroid arteries on each side, and in some cases there is a further supply by the thyroidea ima. Externally the gland is invested by a firm fibrous capsule from which septa extend inwards, partially dividing it into lobules of various sizes. The glandular structure consists of large numbers of closely aggregated follicles which vary in size and shape. The colloid substance which occupies the central space of the alveolus is a yellow glairy fluid which stains uniformly in microscopical sections. Scattered through it may sometimes be seen white blood corpuscles, epithelial cells, and the remains of red blood corpuscles undergoing degenerative changes.

The colloid substance is the secretion of the epithelial cells which line the alveoli Hürthle has shown by observations made on normal glands and on portions of gland in which increased secretory activity had been stimulated either by removal of the greater part of the gland or by ligature of the bile duct so as to cause absorption of bile products into the blood, that the secretion may be formed by the epithelial cells in two ways. The colloid may be either formed in droplets in the cells and then gradually extruded into the lumen of the alveolus, or whole cells may break down and be discharged into the colloid substance, a part of which they thus help to form. In the first method the same cell continues to secrete, while in the second its place is taken by one of the reserve cells. It is doubtful if both these methods obtain during normal secretion, the first being probably the usual manner in which secretion takes place. The large amount of secretion which is found in many alveoli indicates that under ordinary circumstances it is not discharged as soon as it is formed, but that the central portion of the alveolus serves as a reservoir where the secretion is stored for a time before it finally escapes

from the gland.

As the thyroid is a ductless gland it is clear that the secretion can only escape by either the lymphatics or the veins. The evidence we possess shows that the former is the usual path, for it was shown by King and by Horsley, that by applying pressure to the gland the colloid could be squeezed from the acini into the interacinous lymphatic spaces, where it could be seen with the microscope. Biondi and Hürthle have found that this escape of the secretion from the alveolus may occur in two ways. The wall of the alveolus, not necessarily as the result of distension, becomes thinned out at one point and finally ruptures, allowing the colloid to escape directly into the lymphatic space outside, while the empty follicle collapses and forms the starting point for the growth of a new one. Hurthle has found that the secretion can also pass out from the alveolus without rupture of the wall. He injected Berlin blue into the lymphatic spaces of the gland, using an intermittent pressure, and found that it passed on into the interior of the alveoli through minute intercellular channels, in which it could be seen. He also found that when the secretory activity was stimulated the colloid itself could be seen lying in these intercellular channels continuous with the colloid in the alveolus at one end and with that filling the lymph spaces at the other, proving that it was passing from the former position to the latter. By one or other of these methods, the secretion flows into and mingles with the lymph, which bathes the interalveolar spaces of the gland, and with it flows along the path already described to be discharged into the blood stream in the innominate vein, and so distributed to all parts of the body.

No doubt, as in other glands, the activity of secretion varies according to circumstances. Of these, however, we possess but little information Stimulation of the laryngeal nerves or of the sympathetic with the faradic current produces no change indicative of increased secre-Pilocarpin produces a marked increase in the secretion of the colloid, as was shown by Wyss, and Schäffer found that the changes produced in the cells were similar to those which occur in other secretory glands under the stimulating influence of this drug. As already mentioned, the presence of an excess of bile constituents in the blood after ligature of the bile duct also stimulates thyroidal secretion. Removal of the greater part of the gland was also shown by Hürthle to serve as a stimulus to more active secretion in the remaining

portion.

At one time the thyroid gland was considered to be an excretory rather than a secretory gland, and the excretion a mucinoid substance, the retention of which led to an accumulation of mucin in the body and the production of the subcutaneous swelling in myxœdema

Further investigation has shown that the colloid substance is a true secretion which does not contain mucin. Our knowledge of the actual composition of this secre-tion is by no means complete, but several important constituents have now been separated from it. Most of those who have examined the composition of the secretion have considered the proteids to be the important and active constituents of it. Notkin regards thyreoproteid, a substance which he isolated from the gland, as an active constituent which behaves like an enzyme. Gourlay found that a nucleoproteid was the only proteid to be obtained from the thyroid in any quantity, and that it contained phosphorus, which by Morkutun's analysis has been shown to amount to 0.32 per cent. Baumann and Roos made the important discovery that the colloid substance contains iodine in an organic combination with proteid which they named "thyroiodin." This substance contains 9.3 per cent. of iodine, and 0.56 per cent. of phosphorus.

Hutchison has found that two proteids are contained in the gland-a nucleo albumen, which is contained in the epithelial cells and the colloid material which fills the acini. The formed secretion of the gland is split up

by gastric digestion into two parts, one of which is proteid, contains only a small amount of iodine, and has but slight physiological action; the other is non-proteid, contains more iodine, and all the phosphorus of the original colloid, and is more active in removing symptoms due to loss of thyroid secretion than the proteid portion. S. Fraenkel obtained a crystalline substance with the formula $C_6H_{11}N_sO_5$ from the gland, which he named "thyreo-antitoxin." There is, however, no satisfactory evidence to show that this body is endowed with active properties.

It is evident from these observations that the secretion is a complex body, and we cannot as yet say whether its remarkable properties depend on one or, as is more probable, several constituents. Be this as it may, we shall now consider what functions are fulfilled by the secretion as a whole, for that is the form in which it mingles with the blood, and is thereby conveyed to the

tissues

A large amount of valuable information as to the properties and functions of this secretion has been obtained by observing what occurs when it is no longer present in the blood. This state of affairs is easily brought about by removal of the gland from an animal. Owing to the superficial position of the gland in the neck, this operation can easily be performed so as to entail no other secondary result than the loss of thyroid secretion forthwith, provided only that the parathyroid glands are not attached to the gland and removed with it, in which event the effects observed are the results of thyroidectomy plus parathyroidectomy. In man the results of failure of the normal supply of thyroid secretion from disease of the gland are seen in primary myxædema, and from removal of the gland for goitre in secondary myxædema, or cachexia strumipriva, as it is also called.

My own observations of the results of thyroidectomy have been made on rabbits and monkeys. It has, however, been shown that although no effects have been observed in fishes; in lizards, and snakes, the operation is followed by loss of strength and activity, ending in

death in the course of a few weeks.

My own observations show that, although the immediate effects of thyroidectomy are very slight, after a long interval a chronic cachexia develops closely resembling myxœdema in man. Thus in two rabbits which were kept for a long time under observation after the thyroid gland had been removed, there was an early development of hebetude and loss of appetite. No further change was noticed until an interval of eleven months in one case and twelve in the other had elapsed after the operation. After this, in addition to the hebetude already mentioned, swelling of the subcutaneous tissues, dryness of the skin, loss of hair, and subnormal temperature developed, an entirely different condition to that described by Gley after removal of the parathyroids as well. These slides show you the appearance of one of these animals killed eleven months after the operation, and the ears of the other killed twenty-one months after. The ears were very dry, and rough, and cold to the touch, though they flushed readily when handled. The edges of the ears were dry and cracked to a depth of \(\frac{1}{2} \) in. In many places this dried margin had broken off, leaving an irregular outline to the ear. In a third rabbit, which was kept for twenty-seven months after thyroidectomy, no symptoms appeared. When the animal was killed the reason of this was found to be that some of the glandular tissue had unintentionally been left at the time of the operation, and had undergone compensatory hypertrophy. The total amount of thyroid tissue found weighed only 0.07 gram, or about one-third the weight of a complete gland, but it had been sufficient to maintain an adequate supply of secretion for more than two years.

Dogs and cats both develop a rapidly fatal cachexia after thyroidectomy, but the most important results of all have been obtained in monkeys, which have been employed by Munk, Horsley, and myself. In the bonnet monkey (macacus sinicus), which I have used, with one exception, in all my experiments, a parathyroid gland lies in close connection with, or actually embedded in, each lobe of the thyroid gland. As a result of this, when the thyroid gland is removed the parathyroids are

removed along with it. It would be difficult to remove the one without the other, for distinctly as the parathyroid can be seen in a transverse section, it is much more difficult to see it during life while the gland is in situ. In two recent experiments I was unable to detect, even with a lens, the parathyroids on either side and remove them without the thyroid gland; they were, however, easily seen in transverse sections of the lateral lobes after removal of the whole gland. It is, therefore, important to bear in mind that thyroidectomy in the monkey involves removal of the parathyroids as well, so that the symptoms which occur afterwards are not solely due to loss of thyroid secretion, but in part are due to loss of the parathroids as well.

I have removed the whole or a part of the thyroid gland in nine bonnet monkeys and one rhesus monkey, in four of the former the symptoms were allowed to develop with the object of testing the influences of various preparations of the thyroid gland upon them. Some symptoms also occurred in the others, but these four form the basis for the description of the symptoms which result from the operation. These symptoms have been very carefully described by Horsley, but they have such an important bearing upon the whole subject that I shall briefly describe what I was able to observe in my own experiments.

After the operation the animals have been kept in a room, the temperature of which ranged between 60 degs. and 70 degs. F. In about five days the symptoms first begin to develop, the early symptoms being entirely nervous. One of the first to appear is a fine regular tremor, which is most easily seen in the upper limbs, but which is also plainly visible in the lower limbs as well when the animal is held with the feet unsupported. Along with the tremor there is a marked change in the whole demeanour, which is the more noticeable owing to the naturally lively disposition and active habits of the healthy monkey. There is progressive apathy, with loss of natural curiosity and interest in surrounding objects, while the temper is irritable, interference being resented. There is loss of activity, as the animal sits still in one place on a perch or on the floor of the cage for long periods without moving and increasing loss of muscular power, as climbing is done more slowly, and evidently with greater effort, as the symptoms advance. attitude assumed is characteristic, the head is bent, the trunk curved forward, and the knees drawn up. so that the chin rests upon them, the joints of all four limbs being in a position of flexion. Contractures owing to tonic spasm of the flexor muscles frequently occur; in fact, I believe this attitude is partly a result of these contractures, as the limbs are often found to be rigid when it is adopted. Clonic contractions of the muscles are common. There may be a single contraction of a group of flexor muscles, or a series of three or four may involve all the flexors of one arm, increasing in intensity until a position of extreme flexion at all the joints is reached, after which relaxation takes place until another series occurs. Irregular fibrillary contractions of the superficial muscles are often visible through the skin. In consequence of these symptoms the gait is stiff and unsteady, and when the contracture is excessive the animal is obliged to walk on the heels owing to the tonic spasm of the flexors of the ankle raising the toes and sole of the foot from the ground. There is a marked tendency to fall over backwards, so that if a banana is held over the animal's head it loses its balance in looking upwards at it and falls over backwards, and a very slight push when the animal is sitting has a similar effect. True epileptic fits of greater or less intensity may occur. There may be a sudden loss of consciousness, so that if the monkey is on the perch at the time, it falls to the ground. The temperature at first is raised and irregular, but soon becomes subnormal.

During the second and third weeks the myxedematous swelling becomes distinct, and as in man is most apparent in the face. Both upper and lower eyelids become swellen, and with this there is sometimes transverse wrinkling of the forehead. Both lips are also swellen by the elastic cedema. Examination of the blood shows

that the red corpuscles are diminished and the white increased in number.

Without giving any further details of this interesting condition, its resemblance to primary myxedema in man is remarkable. The course of the symptoms is much more acute than in man, partly because the supply of thyroid secretion is cut off suddenly by the operation, while in primary myxedema the supply only gradually fails as the disease of the gland advances.

In both conditions we have the same progressive loss of mental and bodily activity, subnormal temperature, elastic subcutaneous cedema, dry skin, and loss of hair. In the monkey we have, however, acute nervous symptoms which do not occur in primary myxcedema, though some have been observed after thyroidectomy in man. I would suggest, however, from the results of removing the parathyroid glands in rabbits and other animals, that these symptoms are in part due to the loss of the parathyroids, which, as we have seen, are removed along with the thyroid, This view receives further support from the fact, which will be considered later, that these acute nervous symptoms are not readily controlled by treatment with thyroid extract as might be expected were they purely thyroidal in

Opportunities for observing the effects of total thyroidectomy in man have occurred in cases in which that operation has been performed for goitre. It is well known that in a certain number of these cases, as a result of the loss of thyroidal secretion, symptoms develop which are identical with those of primary myxœdema. Indeed, it was the striking similarity between the two, noticed by Sir F. Semon, which led to the appointment of the committee by the Clinical Society, whose report proved the identity of the two conditions and their dependence upon loss of function of the thyroid gland.

In man only three of the diseases which occur in the thyroid gland appear to be capable of causing a sufficiently destructive lesion of the secreting cells to materially diminish the amount of secretion. Syphilis and Syphilis and actinomycosis of the gland have thus caused myxedema. If these diseases are successfully treated the gland recovers, sufficient secretion is once more formed, and the myxœdema disappears. The great majority of cases of primary myxedema are due to a fibrosis of the gland with atrophy of the secreting epithelium. Unfortunately we know very little as yet of the cause or mode of origin of thyroidal fibrosis.

It may, according to the older views, be regarded as a chronic inflammation a chronic interstitial thyroiditis as a result of which new fibrous tissue is formed, which by its slow contraction and constriction of the blood vessels and alveoli leads to the destruction of the epithelial cells. On the other hand, it seems more probable that the atrophy of the glandular tissue take place primarily as the result of the action of some toxic agent, and that the fibrosis is only a replacement fibrosis, such as occurs in the spinal cord and elsewhere after more highly organised structures have been destroyed.

The symptoms of myxeedema which occur in man as a result of this destructive disease of the gland were so ably described by Dr. Ord in his Bradshaw Lecture last year that they are familiar to all. I should, however, like again to draw attention to the fact that there are many cases of early thyroidal fibrosis in which the symptoms are not nearly so definite as in the advanced cases. I have endeavoured in a recent paper to show what are the chief characteristics of these cases—such as slight subcutaneous swelling and dryness of the skin, subnormal temperature, certain striking subjective nervous symptoms, &c. The opportunity of examining the condition ptoms, &c. of the gland at this early stage can only arise if death should occur from some accident or intercurrent disease. In the absence of definite information we can only conjecture that a much earlier stage of fibrosis will be found, for it is evident that in any given case the severity of the symptoms will vary directly with the amount of atrophy of the glandular structure.

The gradual changes in the appearance of a patient suffering from slowly progressing fibrosis of the thyroid gland will be illustrated by some photographs which will be

shown at the next lecture, in which I shall deal with results of disease of the thyroid gland in the young and the rational treatment of myxcedema and cretinism.

Clinical Records.

WESTMINSTER HOSPITAL.

Erysipelas Migrans with High Temperature,

(Under the care of Dr. MURRELL.)

Mrs. S. suffered from pain in the lumbar region and a sensation of chilliness from November 10th to 17th, but she had no distinct rigor. On the 18th the skin over the bridge of the nose and under the eyes was red and shiny, and there was some tenderness. She had no sleep that night On the 19th the whole face was red and swollen, and had to be covered with flour. On the following day she suffered from persistent vomiting. She continued to get worse, until she was admitted into the hospital on the 24th. Her husband stated that they had been married for five years, and that he had known her for three years previously, and that she had never met with any accident or injury. Her grandmother had erysipelas very badly, and patient's sister had an attack about ten years previously.

Patient's temperature on admission at 6 p.m. was 104.2 degs. and at 10 p.m. 104 8 degs. A bright-red shining blush extended over the whole face and half-way up the forehead. There was considerable eddema of the eyelids, which the patient was unable to open, and the lids were swollen and thickened. The tongue was dry, and she had much difficulty in swallowing. She was carefully examined, but no wound or abrasion was found either on the skin or on the mucous membranes. Her lungs were normal. The face was covered with cotton wool, and she was given 40 minim; of perchloride of iron every four hours. The following day the redness extended from the face downwards to the left side of the neck. The temperature at night was 105.2 degs., and she was delirious. She was sponged with tepid water, but this had to be done carefully, as the pulse was weak and she showed signs of collapse. The delirium was quieted by the administration from time to time of a grain of morphine hypodermically. On the 30th, at 3 a.m., the temperature rose to 1074 degs., she was wildly delirious, and was controlled with difficulty. At 7 p.m. the temperature had fallen to 99.2 degs., but at 3 a.m. on the following day it was 1060 degs. The rash was desquamating on the face and forehead, but was extending down the back. She took milk, beef-tea, and stimulants freely. Her pulse was 128, of fair volume, and there was no albumen in the urine. For some days there was very little change. The temperature was from 101 degs. to 102 degs. in the morning, and from 104 degs. to 105 degs. in the evening, the pulse being 120. The patient was in a condition of low muttering delirium, and was constantly picking at the bed-clothes. The rash slowly and steadily progressed downwards at the rate of about 1½ in. a day until it reached the first dorsal vertebra. On the 18th patient was found to have a fluctuating swelling on the occipital protuberance from which pus, watery and offensive issued freely on pressure. In addition there were two sloughs on the scalp, one about 2 in. by $\frac{1}{4}$ in., and the other $1\frac{1}{4}$ by $\frac{1}{4}$ in., the surrounding tissues for an area of 44 degs. being boggy. This was freely laid open by Mr. Guy Coltart by means of three incisions, each about two inches long, and the wound was irrigated with 1 in 20 carbolic acid, and then dressed with hot boracic acid fomentations. The patient gradually sank and died on the morning of the 10th. A post-mortem examination was made six hours after death, but nothing of interest was found. The lungs were normal with the exception of hypostatic congestion, and some old adhesions at the apices

Remarks by Dr. MURRELL.—This case is of interest from the high temperature, 1074 degs, and from the fact that life was maintained for 18 days after admission. If we accept the 10th as being the first day of the illness, she managed to struggle on for exactly a month

Death was warded off by the large quantity of nourishment she was able to take, and by careful nursing. It is curious that with the exception of the surgical incisions no wound or abrasion was discovered either during life or post-mortem. It is possible, however, that there may have been some abrasion of the cuticle or of a mucous membrane which escaped detection, or may have healed during the period of incubation, and before the patient came under observation. Erysipelas is an acute contagious disease characterised by a special inflammation of the skin caused by the streptococcus erysipelatos. How the streptococci managed to get into the system in this particular case is by no means clear, nor is it very obvious why the disease should have assumed such a virulent form. It is well known that people who are the subjects of chronic alcoholism or of Bright's disease are especially predisposed to erysipelas, and often do badly, but this woman was temperate, and there was never more than a trace of albumen in the urine. The mortality from erysipelas in hospital practice is only 7 per cent., and 4 per cent. in private practice, but the prognosis in *E. migrans* is less favourable. The treatment was purely espectant, for although it has long been customary to give large doses of perchloride of iron in this disease there is no evidence that it modifies its course. Tepid baths, or cold baths, to reduce the temperature might have proved useful, but this object was attained by tepid sponging |Her condition from the first was so serious that the safest course seemed to be to trust to good feeding and careful nursing.

The case affords an unfortunate illustration of the risks run by house physicians and house surgeons in the discharge of their duties. Mr. Guy Coltart operated on the patient on December 8th, and on the morning of the 22nd he performed a post-mortem examination on a non-septic case and slightly punctured his finger. At half-past one on that day his arm was much inflamed, he looked extremely ill, and was unable to go round the wards. The wound was promptly laid open and cauterised with pure carbolic acid, but in spite of this precaution he developed symptoms of blood-poisoning, and for many weeks was in an extremely critical condition. It was not until long after this unfortuate woman's death that it was known that quietly and unostentatiously, in spite of the hard work which the post of house physician involves, Mr. Coltart had devoted all his spare time to looking after this patient. It is difficult in adequate terms to express our admiration of his conduct, which reflects credit not only on his hospital, but indirectly on every member of the medical profession.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY. MRETING HELD THURSDAY, MARCH 23RD, 1899.

The President, Dr. H. Macnaughton-Jones, in the Chair.

Specimens

MR. CHARLES RYALL showed three specimens of "Uterine Myoma Removed by Abdominal Hysterectomy," notes of which we hope to publish in our next. In the discussion that followed,

Dr. F. A. Purcell commented on the accident in Mr Ryall's first case: intestinal obstruction might occur from traction on the mesosigmoid when there was any difficulty in securing the uterine artery, leading to kinking of the bowel. The same complication might occur from intestinal adhesions. The second case showed the value of transfusion; until lately this measure was not resorted to as often as it deserved; it gave very good results. Rupture of the abdominal wound was a rare occurrence; the triple method of suturing the abdominal wound was usually a safeguard. In Mr. Ryall's case the accident was probably due to the vomiting from which the patient had suffered.

Dr. Herwood Smith thought that Mr. Ryall had set an example worthy of being followed in bringing forward accidents that had occurred in his cases. He asked Mr. Ryall whether in the first case the gut might have been separated from the stump, thus avoiding the necessity for a fæcal fistula. Referring to the second case, he remarked that catgut was not a good material for suturing the peritoneum, as it was apt to become absorbed too soon. For the other layers the material of the suture was of less importance.

Dr. HERBERT Snow considered that the plan of giving an aperient by the mouth on the second day was not a good one, for it might set up vomiting, which might be

lifficult to control.

Dr. Hodeson asked whether the condition of the kidneys had been ascertained in the second case; the symptoms appeared to him to be more than were accounted for by the vomiting, and the accident to the abdominal wall.

Dr. Winson Ramsay (Bournemouth) said he was very interested in the second case. He held the view that the middle line was the only place in which an abdominal wound should not be opened. He always used an incision through the rectus muscle, and in over 200 cases of abdominal section he had never had any bad results. He had had only one opportunity of reopening a wound, and he then found that the three layers were well united. The only objection that was made to the lateral incision was that some of the parts of the pelvis could not be got at so easily; but it was merely a theoretical objection, and in practice no difficulty was found. He believed that in many cases hernia of the wound occurred, of which the operator heard nothing.

wound occurred, of which the operator heard nothing.

The PRESIDENT observed that there were several points of importance in Mr. Ryall's specimens. The first was the diagnosis between intestinal obstruction and obstructive peritonitis, and this was often a very anxious point. They had to rely on the countenance of the patient, the position of the pain, the character of the vomiting and the difference in the temperature: the latter was high in peritonitis; in intestinal obstruction it was generally low, as in Mr. Byall's case. The second point was the importance of transfusion. It should be resorted to not only after, but if necessary during an operation; and the apparatus with the saline solution should be in every operating theatre For the suture of the wound, he always used fine silk for the peritoneum, silk or silkworm gut for the fascia, and silkworm gut for the skin. He would like to know how far Mr. Ryall had proceeded by the vagina in the third case before opening the abdomen. He thought that such cases were best dealt with through the abdomen in the first instance.

Mr. RYALL, in reply, said that he found in the second case that the peritoneum had torn, and the fascia sutures had torn through. As to the temperature as a means of diagnosis of intestinal obstruction, he did not regard it as reliable. In reply to Dr. Heywood Smith's question, he would remark that a fæcal fistula in the sigmoid or indeed in any part of the large intestine, healed readily, differing markedly from one in the small intestine where the coats were much thinner. For suturing the peritoneum he did not think that silk was necessary because here union took place within a few hours; and Mr. Greig Smith in many cases did not suture the peritoneum at all. The patient had had an aperient—viz., 5 grs. of calomel; but there was no true vomiting, only a constant retching. In reply to Dr. Hodgson, he could not say whether the kidneys were examined at the post-mortem. There was one objection to opening the abdomen through the rectus—viz., the cutting off of the nerve-supply of the part internal to the incision. Replying to the President, he operated by the vagina in the third case, thinking it might be a polypus.

Dr. Winson Ramsay showed the following specimens:—1. Two Uteri removed through the Vagina. 2. A Myoma (? Sarcoma) removed by Abdominal Hysterectomy. 3. A Specimen of Tubal Abortion. 4. A Modified Broad Ligament Needle.

Dr. Purcell referred to a case of ectopic gestation occurring twice in the same patient, the details of which he had already narrated before the Society.

Dr. Heywood Smith asked whether the large myomatous tumour had been examined microscopically to determine whether it was really sarcomatous. With regard to

the tubal abortion, the mole, having remained in the tube, seemed too small to cause so much hamorrhage. He noticed that in the specimen the fimbrize were much thickened, and suggested whether this might not have been the source of the hæmorrhage.

Dr. ARTHUR GILES complimented Dr. Ramsay on the care he had shown in dealing with a difficult complica-tion-viz., the proximity of the ureter to the myoma in his abdominal hysterectomy case. Unless great vigilance were exercised, the ureter was easily wounded in this position. With regard to the case of tubal abortion, he would remark that it was strictly an instance of missed tubal abortion; and the presence of the mole in the tube was sufficient to account for the continuance of the hæmorrhage by keeping the tube distended. A parallel was to be found in incomplete uterine abortion, where a portion of the ovum retained in the uterus was sufficient to keep up hæmorrhage by preventing uterine contraction. The first two specimens shown were excellent examples of the kind of uterus that was best removed through the vagina; he thought that the practice of removing very large tumours by this route was likely to hinder the wide adoption of vaginal cœliotomy.

The President asked Dr. Ramsay whether he had used Deschamp's needles; they were very similar to

those that Dr. Ramsay had shown.

Dr. Ramsay, in reply, first reverted to a question previously raised, viz., the paralysis of the rectus muscle after lateral incisions, and said that paralysis did not occur unless one of the tendinous intersections of the muscle were cut through. With regard to the large myoma, a part of it was found at the operation to be cystic, and contained blood; he did not think at the time that it was malignant: it was only the subsequent history that had suggested this view. In the case of tubal abortion, he thought that the blood came from the mole itself.

Dr. James Oliver showed a photo of a fibroid of the ovary with extensive localised extravasation of blood under the capsule of the tumour.

Dr OLIVER then read a paper on

ADENOMA UNIVERSALE OF THE ENDOMETRIUM

which will be found in another column under the heading Original Communications. In the discussion that followed

The President observed that they had listened to a philosophical paper, whose references to comparative anatomy added both value and interest to the paper. He gathered that Dr. Oliver did not consider it to be a case of malignant adenoma; and that he thought that the first interference had made the case worse. If this were so, it would be an argument in favour of early hysterectomy rather than of repeated curetting. He had himself had a case of adenoma which he curetted; this was followed by a malignant condition of the uterus, which in the end killed the patient. Yet he thought that most men in dealing with such a case would proceed to curette the uterus, rather than at once perform

Dr. HERBERT Snow wished to protest against the use of the word adenoma, which was used in many senses, and consequently led to confusion. In the photo, the growth certainly looked malignant, though in that case one would not expect it to go on for ten years. His view of the case would be that the patient had an endometritis which, on curetting, became a true malignant disease. He would like to ask whether the later stages were accompanied by any of the symptoms of malignant

Dr. P. Z. HEBERT took objection to the suggestion of reversion in this case. In order to show any probability that such a condition was a reversion to type, it would be necessary to show not only that horned ruminants present such characteristics, but also that the ancestors common to both man and the horned ruminants presented the same characteristics before the divergence of the common stock into two distinct species took place; and this would be a rather difficult task, considering the remoteness of the period. Characters which might have developed after that period in one or other of these species could not be reverted to by the other. In othe words, man could only revert to characters that had been volved in the direct line of descent. The comparison was also imperfect, inasmuch as in one case they had a pathological, and, in the other, a physiological condition.

Dr. OLIVER, in reply, said that when he first saw the patient the size of the tumour was about the same as when he did the hysterectomy; but at the outset he did not attempt more than the removal of the polypi. These were found on examination to be adenomatous, but the patient continued quite well then for two years. She had no pain at any time; nor had she a watery discharge until after the curetting, which removed the surface of the glandular tissue. He did not regard the presence of such a discharge as any indication, by itself, of the existence of malignant disease.

ROYAL ACADEMY OF MEDICINE IN IREL AND. SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, FEBRUARY 17TH, 1899.

The President, Dr. H. C. Tweedy, in the Chair.

Dr. Grimshaw read a paper on "Tuberculosis in Ireland and its Prevention," an abstract of which we publish elsewhere.

After this paper was read the following resolution was adopted. Proposed by Dr. John W. Moore, President R.C.P.I., seconded by Dr. McWeeney:—"That the Section of State Medicine having an accurate knowledge of the prevalence and mortality of pulmonary consumption and other forms of tuberculosis, hail with pleasure the movement to control this destructive group of infec-tive diseases, which has been inaugurated by the British Medical Association. The Section urge upon the Council of the Royal Academy of Medicine in Ireland, as a matter of public professional duty, to cooperate in every possible way with those who are engaged in the present determined effort to cope with tuberculosis, now proved to be the deadliest scourge of the human race."

ON THE DEATH-RATE FROM TUBERCULOSIS, AS EXEMPLIFIED IN THE MALE POPULATION OF ENGLAND, FOR THE FIVE YEARS 1891-5.

Dr. MARTLEY read a short paper on the above subject. After pointing out that the deaths from this cause were nearly as numerous as those from the whole group of zymotic diseases, and that they annually averaged about 240 per 100,000 living, he drew attention to the very unequal mortality at different ages, tuberculous disease being most fatal in the first few years of life, and again, though to a less degree, about 40. However, on correcting the county rates for varying age distribution, he found that there was comparatively but a slight difference, and that for all practical purposes, sufficiently correct results could be obtained by using the crude rates.

THE BACTERIOLOGICAL ASPECT OF TUBERCULOSIS.

Dr. McWeeney read a paper on this subject, and demonstrated a series of illustrative microscopic preparations and photographs. With regard to the morphology of the tubercle fungus he mentioned that he had never failed to detect genuinely ramified forms in sputum whenever he had leisure to seek them out. The type of ramification was that of the genus cladothrix, and from the researches of Firchel, Coffin Jones, Hazo Bruns, and Ledoux Lebard, there could be no doubt of the biological affinity of the tubercle fungus to streptothrix and actinomyces. He gave reasons for refusing to admit the spore-nature of the unstained bodies so often found imbedded in the rods, and pointed out the hygienic importance of that fact. He emphasised the value of the staining reaction long considered to be peculiar to the tubercle and leprosy bacilli, but now known to be shared by a smegma bacillus, and by the pseudo-tubercle bacilli isolated by Mockler and others from cow-dung by Mockler from the leaves of Timothy grass near the Greebersdorff Sanatorium, and by Rabinowitsch, from butter. Cultures of the three last-named organisms were demonstrated, as well as slides showing their remarkable resemblance to the genuine tubercle organism. The cause of the staining reaction was the presence in the sheath of the bacillus of a peculiar wax, as was shown

last year by Aronson. This underwent gradual extraction by alcohol and ether, with the result that the bacilli lost their specific staining reaction, a fact which may account for their gradual disappearance from tissues that have been treated for reactionary purposes with these substances. The relation of the bacillus of human to that of avian and piscine tubercle was discussed, and the discovery by Ledoux-Lebard of the bacillus of fish-tuberculosis and the recently demonstrated inoculability of poikilathermous animals with a variety of a bacillus capable of thriving at ordinary temperatures were pointed out as important recent additions to our knowledge. He concluded by earnestly deprecating over-zeal in the adoption of measures intended to be preventive, but which by involving irksome restriction or intolerable publicity would speedily be found to defeat their own purposes.

DISTRIBUTION OF TUBERCULOSIS IN IRELAND.

Dr. P. LETTERS, by statistical tables, sought to prove that tuberculous disease throughout Ireland-tabes mesenterica and tuberculous meningitis more so than phthisis-was regulated almost exclusively by aggregation of population. Small towns and villages bred tuberculosis largely. He controverted all theories referring the prevalence of Irish tuberculosis to meteorological or climatic causes, or to the proportionate amount of bog and barren mountain land, to surface elevation, or to geological formation These did not operate as influential factors, or their effects could not be measured by death-rates recorded over large areas. In the counties, death-rates per million living from (1) takes mesenterica and tuberculous meningitis combined, and (2) from phthisis, correspond so closely with the several degrees of urbanisation as to leave no reasonable doubt of a casual relationship. This line of argument led to the conclusion that tuberculosis, as found in Ireland, is essentially a town and village bred disease, exclusively rural localities showing next to no mortality from tabes mesenterica and tuberculous meningitis, and greatly reduced death-rate from phthisis. The most tuberculosis region in Ireland extended along the eastern and southeastern seaboard, and was mapped out by the counties of Antrim, Down, Dublin, Wexford, and Waterford. The least tuberculosis was found in a compact region in the north-west comprising the five counties of Donegal, Leitrim, Cavan, Fermanagh, and Longford. These two regions contain respectively a high and a low percentage of urban population. A table giving the percentage of inhabitants of towns over 500 to the total population in each of the thirty-two counties showed that, where the town-dwelling population was high, so also was tuberculosis, and vice versa. Freedom from tuberculosis, or the reverse, in the smaller areas of Poor-law unions throughout the country, depended on the same general law of aggregation into town and village communities. Kerry, taken as a whole county, was statistically rather tuberculous Divided into two regions, North Kerry, including the unions of Tralee, Listowel and Killarney, and South Kerry, the remaining unions of Dingle, Cahirciveen, and Kenmare, twenty of the Irish counties are found to be less tuberculous than North Kerry, while South Kerry is considerably freer from tuberculosis than any whole county in Ireland. This was explained by the fact that the per-centage of urban population in South Kerry is only nine, while in North Kerry it is nineteen. A point to which Dr Letters directed special attention was that the most correct test of the tuberculous character of a locality is when the mortality from tabes mesenterica and tuberculous meningitis combined bears a high rate to that from phthisis. This high proportion of juvenile to adult tuberculous mortality in Ireland invariably corresponds with a high degree of urbanisation.

Dr. John M'Murray, whose term of office as Mayor of Bootle, recently terminated, has been presented with a horse and brougham and an illuminated address, as expressing the acknowledgment by his fellow-townsfolk of the ability and courtesy displayed by him during his year of office.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, April 1st, 1899.

HYPERTROPHY OF THE PROSTATE.

AT the meeting of the Surgical Society, M. Monod spoke on the ligature of the vessels of the spermatic cord for hypertrophy of the prostate. A patient suffering from that affection entered his ward for acute retention of urine. During three days, it being impossible to pass a catheter, the bladder was tapped, but finally a fine instrument was passed and left in situ. At the end of a week M. Monod placed a ligature on the vascular pedicle of the testicle, and in a short time the patient was able to micturate freely. As to the spermatic gland, it diminished slightly in volume, without, however, presenting any tendency to sphacelus. M. Monod considered that the benignity of ligature of the spermatic vessels towards the nutrition of the organ could be explained by the fact that when the vas deferens was separated from the vessels about to be ligatured, the artery of that canal is so intimately associated with it that it escaped being tied, and although of exceedingly small calibre, is sufficient to maintain the nutrition of the gland.

M. Regnier thought that his colleague was particularly fortunate in the above case, for ligature of the spermatic vessels provoked frequently lesions of the testicles, especially if the operation was not completely aseptic.

Resection of the vas deferens exercised the favourable influence on the micturition trouble caused by hypertrophy of the prostate without having any evil effect on the nutrition of this gland. He could cite several cases of his own to confirm this fact. In one case the resection of the deferens canal was done on both sides, and not only did all retention disappear, but the genital function persisted.

M. Bazy said that it was a fact that resection of the deferens canal, as Sir Astley Cooper pointed out long ago, in no way interfered with the nutrition of the testicle, but, on the other hand, the operation had no effect on the hypertrophied prostate.

HECTIC FEVER OF CONSUMPTION.
Arsenious acid, † gr.;
Salicylate of soda, 5iiss.;
Starch and distilled water, q. s.

Divide into 100 pills (should not be rolled in powder). Ten to be tak en after each of the three repasts.

ASEPSY IN OPERATIONS.

M. Quenu spoke on the above subject and said that in his practice he endeavoured to come as close as possible to the asepsy ideal. He boiled the instruments in water to which was added borate of soda. The region of the operation was washed with soap and water, alcohol or ether, and a solution of sublimate of mercury, in the order given. As to the asepsy of the hands of the surgeon, and those of his assistants, he considered it very difficult to realise. He estimated that any septic contact was susceptible, even after twenty-four hours, and in spite of energetic disinfection to vitiate the result of the operation. Consequently he abstained from opening any abscess for two days prior to any important operation.

For some time he used gloves of very thin caoutchouc previously sterilised by boiling, and found that they furnished great security. For ligatures he employed almost exclusively sewing thread, for he found it to admirably resist the high temperature. Out of 237 important operations he had a mortality of only 5 per cent.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 30th, 1899.

At the Medical Society Hr. Zadek showed a case of Echinococcus of the Lungs.

The patient was a butcher, 40 years of age, who had all his life had a good deal to do with dogs, and had become infected by them. In February, 1897, he had difficulty of breathing, cough, and hæmoptysis. Catarrhal rales were heard at the bases of both lungs, but no dulness. There was fever and expectoration of mucopurulente sputa, and emaciation from 78 to 53 kgms. Tubercle was diagnosed, although there were no bacilli, and the patient was sent to a health resort, from which he returned after a stay of fifteen weeks, with a gain of 20 lbs. in weight, cough and hemoptysis soon returned, however, and the patient observed skinny membranes in the expectoration. These appeared for a period of between one and two months; and their milky look and the microscopic appearance showed that they were the coverings of ecchinococcus cysts. There were hundreds of them, and they were expectorated easily and without much hæmorrhage. They ceased to make their appearance from Christmas, 1898, the expectoration diminished, and pain ceased. The patient improved in health, and returned to work with a weight of 180 lbs. The physical signs were only slight, and after expelling quantities of cysts there were no signs of cavities remaining, and as percussion gave no evidence the X-rays were tried. These showed clearly the site, size of the collection of echinococci. A shadow the size of an apple was seen clear in the centre on deep inspiration, with darkened From the situation it was evident that an edges. echinococcus of the liver had passed into the lungs. Adhesive pleuritis had prevented the stormy symptoms usually observed in such cases. There was also a shadow in the left lung, between the middle and lower lobes, plainly from a second echinococcus, and the patient in fact did complain of some disturbance in the left side of the chest-There being no mixed infection complicated lung disease had not developed. What would be the end of the disease on the left side could not be foretold. The interesting features of the case were the mild course, the discovery by the X-rays, which had thrown light on the diagnosis, ætiology, prognosis, and treatment. The rays were clearly of great assistance in case of echinococcus of the lungs.

Hr. Levy-Dorn explained the technique of the use of the X-rays. The patient must be required to breathe deeply and then hold his breath. In this way only was it possible to study the relation of the tumour to the diaphragm, and exclude some relation to other objects, which moved on inspiration. The exact seat of the collection was determined by the fluorescent screen.

Hr. Rosenhein showed a boy with

STENOSING HYPERTROPHY OF THE PYLORUS.

The boy was seven years of age, up to five he had been perfectly healthy, and was of healthy parentage. The disease began after a severe attack of measles. The

child began to vomit, awoke in the night and brought up what he had eaten during the day. The appetite was good, and there was no other abnormality. In July. 1897, the speaker discovered excessive dilatation of the stomach; it contained large quantities of decomposed fermenting material, and free hydrochloric acid, but no tumour could be felt. The stomach was washed out and the food carefully selected, and the patient was free from symptoms, but objectively became worse. The probable diagnosis of stenosing hypertrophy of the stomach was confirmed by operation, the pylorus only permitting the passage of a small sound. After recovery from the operation fresh symptoms came on, and at last gastroenterostomy was performed; the pylorus had become adherent. After this permanent improvement set in, the stomach became smaller and its motor function re-established.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 30th, 1899.

SALOPHEN IN INFLUENZA.

In the recent epidemic of influenza this drug has been used with great success, judging from the evidence contributed by a large number of observers. Its advantages of being tasteless, and having no injurious effects are praises frequently repeated in its favour. In cases of influenza, one to two grammes given every three hours, in plenty of mineral water, is held as an excellent remedy for the disease, if not a specific. Smaller doses are recommended as prophylactic in epidemics.

PRIVAT DOCENTS.

This peculiar body of teachers have now formed themselves into a Union with the object of increasing their usefulness and improving their status.

The privat docent is a body peculiar to Austrian schools, and of considerable benefit to a foreigner as an introduction to foreign University ideas. Their avowed combination is to increase this utility by adding to the number of their classes, particularly during the periods of recess. The provincial Universities are invited to join the combination for the regulation of post-graduate classes for Austrian practitioners. Drs. Landsberger, Hartmann, Schmid, Lampa, Jellineck, Hammer, and Prof Finger, have been appointed to act as a representative committee.

FOCHIER ON ARTIFICIAL ABSCESS IN PYÆMIA.

This novel antidote for pyæmic poisoning is still increasing in favour. It seems to be more effectual in cases arising from abscesses forming around the genitals. The modus operandi is to inject two drachms of oil of turpentine into the calf of the leg, which sets up severe irritation, finally resulting in a large abscess.

From the time of injection the rigors due to pyemia cease, and the patient rapidly recovers without any subsequent relapses. The temperature, however, remains high for a few days after the injection, but gradually descends to the normal.

Other infectious diseases from which abscesses result, such as typhoid, erysipelas, osteo-myelitis, pneumonia, &c., have been operated on with equally favourable results.

If the artificial abscess be allowed to remain unopened it will soon become absorbed without any bad result, but

Fochier recommends the abscess to be opened at the earliest opportunity.

ERB's "SYMPTOM COMPLEX."

At the Medical Club Weiss recorded a case of a female, at. 37, who had been received into hospital from the country. Six years ago she had suffered from an abortion, which was followed by pain over the whole body, but she seems to have shortly afterwards recovered her normal health. Three years later she was attacked with severe rigors, vomiting, subsequently becoming unconscious, and in this condition she remained for three weeks. On recovering, it was discovered that she had difficulty in swallowing associated with involuntary movements of the head.

A few months later she was able to move about only with the greatest difficulty. About this time a discharge from both ears commenced. In the autumn of 1897 the limbs became stiff and movements impeded. The speech was also feeble and inarticulate while double vision was also present. Since 1898 she has been an in-patient, and has become very emaciated, but is quite conscious and understands all that is going on around her. The muscles are flaccid and can be passively or actively moved, possessing a good deal of tonus. These phenomena were common to all the muscles of the body. The movement in the eyes and vocal cords were slow. The internal organs were at first normal, although at present bronchitis, decubitus, and albuminuria were present. The breathing is undisturbed, sensibility is intact, and there is no atrophy or trophic disturbance. The electric stimuli are normal, but the tendon reflex is

The tonus of the muscular system increases the complication,

The grey substance is undoubtedly affected, although the original acute fever three years ago may be accepted as the initial point, and probably connected with the pyæmia derived from the aural discharge, while the meninges and medulla oblongata became finally affected.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

SUBPHRENIC ABSCESS .- Mr. CARLESS operated on a girl æt. 22, who had been under observation in the medical wards for some weeks under the care of Dr. Burney Yeo: her symptoms were ascribed to a meal of rabbit, and at first were supposed to be those of typhoid fever; she improved somewhat as a result of rest and careful dieting, but for some weeks her temperature had been 2 or 3 degs. above the normal, and she complained of pain and tenderness in the left hypochondrium. During the last ten days she had had several severe rigors. On examination Mr. Carless stated that the girl looked very anæmic, with sordes on the lips, and was extremely apathetic. Oa stripping the abdomen and chest it was found that the respiratory movements on the left side were less marked than those on the right; tenderness was complained of over the three lowest intercostal spaces and in the left hypochondrium; nothing abnormal could be detected on palpation; there was a patch of dulness a little behind the mid-axillary line, extending up to about the eighth rib, corresponding fairly accurately to the situation of the spleen; over this area

breath sounds were absent, although they were heard to be of a normal character above and behind it. An exploring needle had been introduced three times by the house physician without result; it was admitted, however, that it had not been introduced sufficiently far to traverse the diaphragm. Before operating Mr. Carless stated that the nature of this case was somewhat doubtful, but that he thought it probable that there was an ulcer of the stomach and a localised sub-phrenic abscess. With this supposition in view he proposed to make an incision along the left lower costal margin and explore the under surface of the diaphragm. Should nothing be found in this direction he would examine the posterior surface of the stomach through the omentum, then the spleen and finally explore the pleural cavity. An incision nearly six inches long was accordingly made parallel to the rib margin, and, before the peritoneum corresponding to it was fully opened, presence of adhesions round the stomach was demonstrated; these adhesions partly involved the omentum and fixed it and the stomach to the under surface of the diaphragm. A careful packing of gauze was introduced into the lower part of the wound so as to protect the general peritoneal cavity, and then the adhesions were carefully broken down with the finger. To facilitate this proceeding a projecting costal cartilage was divided, and the costal margin held aside by retractors. Before this dissection had been carried very far a collection of foul pus was opened, and on further exploring the cavity it was evident that the main trouble was tuberculous in nature-A certain amount of caseating material was very caretully removed with a sharp spoon, and the cavity well flushed out with sterilised saline solution. A large drainage tube was then introduced and in order to make it lie comfortably a portion of the costal cartilage mentioned above was excised. Iodoform gauze was packed in around the tube, and the external wound partially closed Mr. Carless remarked that the result of his exploration had been most satisfactory, and that it fully confirmed his opinion as to the nature of the case. His diagnosis had been based on the lack of mobility of the chest wall, on the localised tenderness, and on the fact that the lung seemed to be pushed up and not in any way involved. There had been comparatively but few symptoms of gastric ulcer, but it is not unknown, he said, for such a condition to remain passive. In all probability the present operation would only be sufficient to relieve the immediate symptoms. The projection of the costal margin would be almost certain to prevent satisfactory drainage, and other steps would have to be undertaken to secure this end.

It is satisfactory to state that, two days after the operation, the temperature of the patient had dropped to the normal, and she was evidently very much better.

SEAMEN'S BRANCH HOSPITAL, ROYAL ALBERT DOCKS.

OPERATION FOR RUPTURE OF URETHRA AT BULBOUS PORTION.—Mr. WILLIAM TURNER operated on a coloured man (a Lascar), a stoker on board ship, æt. about 45, who had been admitted about four hours before with hæmorrhage from the urethra appearing at the end of the penis. He had slipped and fallen against an iron bar (a lever), the end of which gave him a slight blow at the anterior part of the perinæum. This was followed by pain and severe hæmorrhage; there were no symptoms of shock, and on examination no tenderness in the peri-

næum. He once passed water before admission which was comparatively clear, showing that there was no rupture of the bladder. A soft instrument was passed down the urethra, and an obstruction met with about 41 inches down, i.e, at the bulbous part, and the instrument could not be passed on into the bladder. There was no swelling in the perinaum three hours after the accident; there was some slight tenderness, and the hæmorrhage was continuous and pretty severe. Under an anæsthetic an instrument (a bulbous staff) was passed down to the obstruction, which again could not be overcome, so the perinæum having been purified and the patient put in the lithotomy position the point of the instrument was cut down upon; it was then found that the catheter passed through a rupture in the bulbous part of the urethra, and its point was in the cellular tissue impinging against Colles's fascia, that is to say, against the deep perinæal fascia. It was then attempted, after putting back the instrument into the urethra, to pass it on into the bladder, but this failed (the rupture of the urethra was almost transverse and about three-eighths of an inch long, occupying the centre and left side of corpus spongiosum); a linear incision was now made in corpus spongiosum about half an inch long into the urethra posteriorly to the rupture and a fold of mucous membrane was found, which had obstructed the passage of the instrument, A Lister's bougie was then passed readily into the bladder; a No. 8 silver catheter was substituted for the bougie and the slit and the rupture of the urethra were stitched completely up with fine silk (partly by continuous suture, partly with some interrupted sutures). The hæmorrhage was from the corpus spongiosum, and the stitching up completely stopped it. Numerous small vessels were ligatured in the superficial part of the wound, which was dusted with iodoform, a piece of iodoform gauze being left in. The catheter was then tied in and rubber tubing attached. Mr. Turner remarked that it was essential to cut down in all these cases, as there was great prospect of complete healing, and the operation absolutely prevented any extravasation; in this case the indications for an operation were specially the hæmorrhage, and the fact that an instrument could not be passed into the bladder. The patient, Mr. Turner thought, must have lost at least a pint of blood, and the rupture was evidently caused by direct contact and not by tearing away the bulbous portion of the urethra from the triangular ligament. From cases he had seen, Mr. Turner considered it was always safer to cut down on all cases of rupture of the urethra in whatever position, which, he said, agreed with the teaching definitely laid down by Hurry Fenwick and H. Morris. As to after treatment, if all goes well, the catheter would be removed in from three to four days. It is better treatment, he pointed out, not to stitch up the perinæal wound superficially in case of any slight leakage of urine from the urethra, or any trouble with the silk stitches, which may entail their removal. These two complications are, unfortunately, rather common in these cases, but the final results of the operation and treatment are admirable.

Dr. Robert Lucas, of Dalkeith, was the recipient a few days ago of a very substantial testimonial in the shape of a bank draft for £350, together with a handsome timepiece and ornaments.

" SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 5, 1899.

THE ENGLISH REGISTRAR-GENERAL'S ANNUAL SUMMARY.

THE annual summary in which the Registrar-General for England so admirably reviews and connotes the statistics of the preceding year is always interesting, because it directs attention to concrete results gleaned from an arid mass of statistics which must remain terra incognita for those among us who are not statisticians by constitution and temperament. From it we learn our position as compared with previous years and with other countries; we can see at a glance whether our national vitality is up to the standard, and whether sanitary science continues to justify its existence by a further reduction in the preventible death-rate. It enables us to detect the unsanitary and ill-governed areas by reason of their huge death-rates, and to gauge the value of preventive and therapeutical measures when applied on a large scale. The summary is useful in that it rubs in the much-needed lesson that, in spite of the much-vaunted progress already accomplished, much more still remains to be done. We find that the wane in the marriage rate which characterised the returns of the last thirty years has experienced a check, that of last year being the highest recorded since 1877, with a corresponding augmentation in the birth-rate, showing that Malthusiasn ideas have not yet gained a firm hold on our young married people. That, we suppose, is matter for congratulation, at any rate from a professional point of view. The returns under the head of infantile mortality continue to afford ground for profound dissatisfaction. The rate for the thirtythree large towns of the kingdom is 178 per 1,000, being eleven per 1,000 above the average proportion

during the last ten years. The eminently preventible nature of this wasteful mortality is rendered evident by the extraordinary differences in the figures for the different towns and the difference is even more striking when particular districts of certain towns are considered separately. The deaths from small-pox were less than some years past, numbering in all only 13, and this figure may prove interesting reading in years to come in view of certain contingencies. While the scarlet fever mortality was distinctly less, that of diphtheria was equal to the decennial average, a somewhat discouraging fact considering the general use of the serum treatment. though, of course, the results of treatment must be judged by case mortality and not by total returns. The deaths from enteric fever were up to the average, but the most marked increase perhaps is that under diarrhea, which is essentially an infantile complaint. The returns for the metropolis present some points of contrast with those of the large towns in the aggregate. In London, for example, the mortality from diphtheria was markedly less than that of the preceeding years, and the deaths from phthisis showed a slight reduction. Although the deaths ascribed to influenza in 1898 were nearly double the number for 1897 they were below the average for the eight preceding years. The returns under this head show a curious oscillation of a rhythmic kind, and we are now apparently on the crest of a rising wave. In conclusion, we find that the death-rate for the total population of the thirty-three large towns stands at 22.2 per thousand living, a rate which compares unfavourably with that of thirty European and American cities with a deathrate estimated at 20.1 per thousand. In Paris the rate was 19.7; in Berlin, 17.3; and New York, 19.1 London, one is pleased to see, still holds her own as the healthiest of the very large cities, with a deathrate of only 18.7.

LEAD POISONING.

THE report of the Special Committee of investigation into the condition of the workers in the Potteries has been at length published, and furnishes a crushing indictment of the present system. Without going into details, its most pithy conclusion may be set forth in the simple statement that an enormous sacrifice of human life is going on daily in this dangerous pottery trade, owing to the more or less unrestricted use of lead in the process of glazing. The scientific evidence with regard to the ill effects of the poison is overwhelming, in spite of the fact, familiar to medical readers, that it is often difficult to determine the remote and sometimes even the immediate symptoms of this subtle and deadly industrial material. Indeed, there can be little doubt that our knowledge of the subject has been almost hopelessly obscured by the non-recognition of cause and effect which has filled in the death certificates of bygone generations with such unsatisfying symptomatic etiology as epilepsy, rheumatic gout, convulsions, paralysis, nephritis, anæmia, and a host of chronic secondary vascular, nervous and organic

troubles, where the one key lay in the word "plumbism." But the rapid and comprehensive advance of modern medicire has changed all that, and the knowledge of the various trade poisonings under every aspect is now an open book which every practitioner may run read, if he be alive to his responsibilities and abreast of the generalities of his profession. The recent inquiry has gone into this part of the question, and established the fact that an immense amount of lead poisoning has been going on day by day in the Potteries. It will hardly be believed that old-fashioned factories still exist where simple elementary precautions for the prevention of poisoning are wanting, yet such is the case, and we learn that structurally unfit premises are at this moment in use. After that statement, any Government which allows places of the kind to continue for a day is incurring a grave responsibility. Indeed, we understand that the Home Office has already issued minute and sweeping notices dealing with the regulation of the special trade processes in question. Young persons are not to be permitted to work in the factories, and various sanitary requirements are to be enforced. Although, no doubt, we have been anticipated in this particular by the departmental advisers, we venture to suggest the absolute necessity of frequent and systematic inspection both of workpeople and of premises competent medical men, who should be appointed forthwith in sufficient number by the central administration. It is to be hoped that Mr. Balfour, who has been stated on high authority to be about to devote his best energies to social legislation. will scotch this potter's poison once and for all. Curiously enough, the slowly evolving light of science has placed a club of Hercules within his grasp. Lead, that for many centuries of historic and pre-historic record has claimed its death toll of the potter, is quite unnecessary for the production of a perfect glaze. That simple proposition contains the germ of all future action; it is the logical basis of reform; its application will eradicate the problem. With no lead in the glaze there can be no plumbism among the potters, and the question of healthy trade environment may be settled upon the lines common to other occupations. With a leadless glaze potting will sink to the level of a comparatively harmless pursuit, apart from the dust, which may be readily provided against in special ways. So far as can be seen no such brilliant opportunity has ever offered itself for an imperative reform at small cost in the whole history of industrial prevention as that which presents itself in the suggested adoption of a lead-free glaze. The scientific evidence in favour of such a step is overwhelming. The public are educated upon the point, and the manufacturers have not offered any really serious opposition to the proposed change. In a case of this kind, however, capitalists should not be allowed to stand in the way of the saving of human life, nor do we for a moment imagine that the master potters have erred hitherto from want of heart so much as from want of knowledge.

future, however, their position will rest upon an entirely different basis. We should hardly have adverted to this aspect of the subject save that in recent bills the Government has seemed to give way to capital in the matter of the abandonment of automatic railway couplings, and of a reasonable standard flash-point for petroleum. It seems clear that immediate action must be taken by the Balfour Ministry with regard to lead poisoning in the Potteries, and in the light of past experience it may be devoutly trusted that all provision against mischief will be made stringent and absolute, with no single loop-hole of permissiveness to may the prospect.

SECRET MEDICAL COMMISSIONS.

IF the very grave charges which the London Chamber of Commerce has brought against our profession are passed by with no more repudiation than the milk-and-water pronouncements of our medical contemporaries, we fear that the public might conclude that there is sufficient truth in the accusations to reduce us to silence, and it therefore becomes necessary for us to return to the subject with a view to a more explicit refutation and disclaimer. The London Chamber of Commerce is a very important body, and its pronouncements cannot be minimised. It has issued an official report which constitutes a tremendous indictment of the commercial honesty of the kingdom, the medical profession being represented by a homeopathic faction of the whole. In this connetion it asks that "All professional and trade bodies, such as those representing the medical, legal, artistic, and other professions and trades, be recommended to make an emphatic declaration on the subject of secret commissions . . . by inserting into their bye-laws a stipulation that any member guilty of the pernicious practice will be expelled." justify a medical authority in acceding to this suggestion the Chamber should be prepared with evidence that the practice of receiving secret commission exists to a material extent our profession, and of this scarcely a shred of evidence is adduced. The witnesses called in support of the charge are two in number, a pharmaceutical chemist and an optician, jeweller, and silversmith, both of whom testify, in a vague way, that secret commissions on medicines and on instruments pass between trader and doctor. Additional to this is the statement of Sir Edward Fry in a letter to the Times that a certain practitioner, after the death of his patient, handed the business card of an undertaker to the relatives. If this be all the proof upon which the Chamber grounds its wholesale indictment of the profession, we say at once that we do not believe a word of the charge. We are aware, also, that certain practitioners of the better class have left themselves open to suspicion of this traffic by systematically writing their prescriptions in hieroglyphics unintelligible to all pharmaceutists save the one whom they patronise, but this very objectionable practice does not necessarily imply that they receive any monetary con-

sideration for such patronage, and it has never been charged that they do. We do not for a moment doubt that there are a few fourpenny practitioners who would take and solicit commission on sticking plaster which they prescribe, but we absolutely deny that these are worthy of being spoken of as even a substantial fraction of the profession. secret traffic has never been complained of, as it would have been certain to be by rival practitioners, and no instance has ever been brought to the notice of the General Medical Council. If it were we apprehend that the question would have to be seriously considered whether it did not constitute "infamous conduct in a professional respect." If such practices existed to any appreciable extent we should certainly know of it, and should, we hope, be ready to acknowledge the abuse and try to stop it, but we firmly believe that outside a very limited class no such traffic exists, and we much regret that the Chamber has made no attempt to substantiate its accusation.

Rotes on Current Topics.

Madame Frain—"Fraudulent or Felonious."

For years past a thriving trade in female remedies has been carried on in the heart of London by one Madame Frain, who has flooded the metropolis with pamphlets and inundated the country with disgusting advertisements. Her position has been repeatedly attacked in the medical journals, but she has been allowed to go her own way unchecked by our Scotland Yard authorities, who seem to think that they have done their duty by seizing a few abortionists red-handed, and that they need not interfere with persons who incite and abet misguided women, either directly or indirectly, to rid themselves of the products of conception. At any rate, it is difficult to arrive at any other conclusion when we find Madame Frain carrying on her sordid trade openly year after year apparently without let or hindrance from the powers that be. Last week an inquest was held in London on the death of a young married woman after abortion, and it was shown, in evidence, she had taken Frain's nostrum for inducing that condition. In the course of the inquiry several noteworthy facts have transpired. First, it was stated by a man who called himself a "herbalist" that the lady's connection with the business had ceased for some time past. Secondly, that the vendor seeks to protect himself by making each customer sign a form to the effect that she is not enceinte, a precaution that would probably be worthless in the face of Frain's printed advertisements and circulars. Thirdly, that Frain's remedies are sold by chemists, a matter that demands instant inquiry at the hands of the Pharmaceutical Society. We have little hesitation in saying that a chemist who deals in abortifacients, open and veiled, should be deprived of his licence forthwith. Fourthly, Frain's manager stated that their stuff was perfectly harmless, an assertion that clearly bears o the point of false pretences. The jury gave as thei

opinion that Madame Frain's business was either fraudulent or felonious, and the coroner alluded to the fact that the proprietors of the concern had taken no steps to disprove the charges recently made against their advertisements in leading medical journals. Again we ask, where are the police?

Infection in Public Vehicles.

FROM time to time a case is published of disease communicated by the exposure of infective patients in a cab. A little stir is made over the scandal at the time, but the storm in the teacup soon subsides, and no one is a penny the worse, as prosecution for such recklessness is rare, and conviction almost unknown. Yet weighed in the balance of probability, a factor that cannot be ignored, the percentage of the known to the unknown must be in this matter simply incalculable, for by the very circumstances of the case discovery of the facts is hard to detect and still more difficult to prove. At the present moment, however, the community is faced with a situation ripe for instant action. Two great movements are afoot, each of them bearing directly on the particular point under discussion. First, there is the great national crusade against tuberculosis, a movement that is gathering every day fresh strength and volume. Secondly, there is the social battle now being waged anent the regulation of street traffic, especially of public vehicles plying for hire. By a happy combination of the practical issues of these two subjects of current interest it seems likely that the cause of prevention might be materially advanced. The root of the matter may be placed in a nutshell. Tuberculosis and many other communicable diseases are spread by infected persons who travel freely in cabs, omnibuses, tramcars, and railway cars. The present system of prevention in such special case is unsatisfactory, as the state of the law is dubious. and practically no provision of any kind whatever is enforced by the local authorities. The reform is no doubt a difficult one to institute, but its existence marks a most serious flaw in the general prevention of communicable diseases. Here is an opening for some earnest worker in public health who may be desirous of handing down his name to posterity.

Margarine Evasions.

BUTTER is butter, all the world over, a sentiment that seemingly forms the text and gospel of the Butter Association, an excellent body that last week, pregnant with sorrows, waited upon Mr. Walter Long. The tale unfolded by these experts furnishes suggestive reading for consumers in general. No one objects to margarine, if sold as such, and distinctly labelled, as the law directs, but when vended either pure and simple or in mixture and paid for as genuine butter then the public most assuredly have a right to The Association have successfully prosecuted many hundreds of offenders in that direction during the past five years, and have thus undertaken work that should have been performed by the They found that out of 500 local authorities. samples of butter sold at a shilling a pound

in apparently respectable shops, over 100 were adulterated with margarine, the majority to the extent of 70 to 90 per cent. They assert that the practice of many retail establishments is never to sell margarine or mixtures across the counter as butter for fear of detection, but to send such stuff to their family customers by van or errand boy delivery. An even more artful trick is that which practically hides the word "margarine" on the wrapper by placing it in the midst of a thicket of flourishes, while the word "butter" in connection with the name of the vendor stands out in overwhelming prominence. The Association propose a label which should bear in bold block type the name "Margarine," only that and nothing more. All this sounds reasonable, and it is to be hoped that the sweet persuasiveness of the Butter Association will prevail upon Mr. Long to carry out the principles clearly adopted in existing margarine legislation, and no less plainly evaded and set at naught by the trickery of tradesmen to the injury and loss of Her Majesty's lieges.

Company Doctoring.

OUR readers are aware that the Pharmaceutical Societies have been making great efforts to prevent co-operative stores and other limited companies from carrying on extensive business as dispensers under cover of a single qualified pharmaceutist who stands as trade sponsor for a whole crowd of unqualified compounders. So far, the societies have not succeeded, but more than a year ago, it occurred to Dr. Tichborne, the representative of the Apothecaries Hall of Ireland in the General Council, that there is a serious danger that the same method may, at any time be applied to medical practice, and that it may be legally possible for a company to be started to supply medical advice and medicine wholesale under cover of some out-at-elbows practitioner. Dr. Tichborne brought the matter under the notice of the General Medical Council, and the result, after much legal advice and cogitation is the following Bill introduced to the Lords by the Chancellor last week ·-

i. It shall be unlawful for a company under the Companies Acts, 1862 to 1898, to carry on the profession or business of a physician, surgeon, dentist, or midwife, and if any company contravenes this enactment it shall be liable on summary conviction to a fine not exceeding five pounds for every day during which the contravention happens.

2. This Act may be cited as the Companies (Medical Profession) Act, 1899.

Typhus in South London.

FROM a recent report handed into the Vestry of St. George the Martyr, Southwark, it appears that typhus has been running a slow epidemic course in South London for many months. In the parish named a case occurred in October last and another in the following February. Following up the history of the cases the Medical Officer of Health, Dr. Waldo, has established a connection between them by a long chain of illnesses and deaths, some of the attacks being recognised as typhus fever, while the fatal cases were certified as due to pneumonia, influenza,

enteric fever, and typhus. The report is valuable from several points of view. It shows the difficulty or, indeed, the impossibility of recognising atypical cases of the disease, which are nevertheless infectious. It also proves the value of careful and systematic investigation of all cases, and the need of co-operation by neighbouring sanitary authorities. The disease was spread in the first instance by the father of a family who refused to go to the St. George's reception house, and who carried off the infection to his daughter's house in another parish, and thereby started the long train of specific sickness which has led to something like sixteen cases, with four deaths. Many persons will be somewhat startled to hear that typhus fever has been abroad in the metropolis for the last six months, and the officers of medical institutions will do well to bear the fact in mind when dealing with obscure cases, especially where there are petechial or anomalous rashes.

A Nostrum Denounced.

MR. BRAXTON HICKS took advantage of the opportunity afforded him by an inquest at Putney last week, to expose what he rightly considers to be a gross fraud upon the suffering poor. It had transpired at another inquest that the father of an epileptic girl had paid several shillings a bottle for a quack remedy called Elepizone, prepared by one Root, at 28, Endsleigh Gardens, N.W., which, it was claimed, would cure fits, epilepsy, and falling sickness. The coroner had this nostrum analysed by Dr. Womack, of St. Bartholomew's Hospital, who testified that each drachm of the liquid contained three grains of bromide of potassium with an admixture of some inert colouring matter, the whole being approximately of the value of twopence. The coroner and Dr. Womack announced their intention of defending any action that might result from this exposé, but the risk is small, for these pernicious nostrummongers know full well that they would find short shrift before a British jury. This nostrum, however, is probably no worse and no better than a myriad other preparations of the same kind, and it would be more to the point if an anti-quack league were formed for the express purpose of publishing analyses of them all in order to educate the public The thing might be worth doing in spite of the fact that the taking of nostrums is with many people a sort of religion, and the habit is consequently open to amendment.

Hospital Case Books for Sale.

If the story told in the last number of Truth be correct anent the sale by auction of twenty odd volumes of the late Dr. Alfred Meadow's hospital case books, we cannot but concur in the condemnation expressed by our contemporary of the conduct of those responsible for such a tactless breach of professional confidences. These case books only dated back to 1873, and doubtless many of the persons whose histories are therein recorded are still alive, and they would certainly resent these histories being made public property. The whole lot only fetched

between three and four shillings, so that the leaves may serve to wrap up butter and cheese. If any aggrieved patient chose to take action we presume the responsible persons might be held liable in damages for their wanton disregard of professional amenities. It would be interesting to know the name of the purchaser, but this it is not in our power to give.

The Presidency of the Royal College of Physicians of London.

It is stated that the struggle for the Presidency of the Royal College of Physicians (London) between Dr. W. S. Church and Sir William Broadbent was really one between St. Bartholomew's Hospital and St. Mary's. The former being the larger school, and having consequently the largest number of supporters, it is not surprising that their nominee should have been successful at the poll. The last member of the school of St. Bartholomew's who was President of the College was the late Sir George Burrows, who held office from 1871 to 1876. It is no doubt an honour to a school to have among its staff the President of the College, and while we heartily congratulate Dr. Church upon the high position to which he has attained, we nevertheless feel bound to confess that so far as work done for and in the profession is concerned, the claims of Sir William Broadbent were not only higher than those of Dr. Church, but higher than those of any other candidate for whom votes were recorded.

A Fatal Ether Explosion.

An extraordinary catastrophe is reported from Rochdale Workhouse Infirmary, where two nurses were fatally injured in consequence of the accidental breakage of a large bottle of ether in the dispensary, and the ignition of the contents. It seems that the dispensary doors were without handles on the inside, thus rendering prompt escape impossible. At the inquest the jury added a rider to the effect that ether bottles should be stronger, and that the Petroleum Acts should apply to this highly inflammable substance. It is to be feared that the strongest bottle made would not resist a fall from a shelf, but some good might be done by requiring ether to be sent out in bottles not containing more than one pound each. We must admit, however, that even one pound of ether would suffice to set the place in a blaze in presence of a lighted gas jet. In fine, this regrettable accident appears to be one against which extreme care alone can afford even an approximate safeguard-

A Volta Centenary.

Volta, the electrician, and inventor of many electrical appliances, was born in Como, Italy, and the inhabitants of that city on May 4th next will celebrate the centenary of the day on which he invented the pile which goes by his name. On this occasion, also, an international exhibition of electricity will be held, a section of which will be devoted to the various medical applications of electricity. Perhaps in this connection it would be worth while to recall the great discoveries made by our country-

man, Michael Faraday, in electrical science. He was the first, for example, to demonstrate the laws of electrolysis, a discovery which alone would entitle his name to be passed down to posterity. As, however, he was only born in 1791, some time must yet elapse before a centenary celebration can be held in connection with his life work. As a chemist he was a great man, but as an electrician he was a greater, and, perhaps above all, he was a native of this country.

Insanitary Stations in India.

THE Government of India have a work before them from which they should not shrink. It is that of carrying out wholesale sanitary reforms in regard to the various stations. Most of the latter, it is reported, are so insanitary that they have become veritable death-traps for the officers and men of the British regiments. The necessary reforms would require either the complete abandonment of the old sites and the selection of new ones, or the enforcement of sanitary principles by which the old stations could be made free from filth diseases. Under present circumstances, many young officers and men who land in India from this country merely do so to die from typhoid after a brief interval. The disease is quite preventible, and the responsibility of the deaths of the young Englishmen entirely devolves upon the Government. No doubt an enormous sum of money would be requisite in order to carry out the necessary reforms; but the Government of India should not shrink from such an outlay in view of the terrible cost of valuable lives which its neglect exacts. The matter is one upon which some questions might with advantage be asked in Parliament, inasmuch as the sooner public opinion is brought to bear upon the urgent necessity for the reforms indicated the better.

The Open-Air Treatment of Tuberculosis.

THE West London Medico-Chirurgical Society have arranged a discussion upon "The Open-Air Treatment of Tuberculosis," which will take place at the meeting of the Society on the 7th instant (Friday next). Dr. S. T. Pruen, of Cheltenham, will open the proceedings by reading a paper upon the subject, and there is no doubt that the theme is one upon which much can be said. It is true that the open-air treatment of tuberculosis is very greatly to the fore at the present time, for which in some measure the "boom" in "matters tuberculous" is responsible. Good, therefore, is likely to come from the dissemination of facts and opinions in connection therewith, for which the Society above mentioned have made timely arrangements.

THE extremely trying east winds of the last weeks has run up the death rate in Dublin to 323 per 1,000 of the population, being two per 1,000 over average. The deaths from respiratory diseases the week before last reached 59, being 11 over average. Thirty-one deaths were from bronchitis, and 19 from pneumonia.

Another Poison Romance.

This is not the big gooseberry season or we should experience less difficulty in explaining the curious plethora of sensationally ridiculous stories about attempts to poison whole families with a few drops of chloroform on a handkerchief pushed under a bed room door, and the more recent tragedy reported from Philadelphia, where a certain society lady is asserted to have been the victim of an attempt to murder by means of a poison emanating from a bookmark placed in a work which some disappointed lover or female rival had sent her. She is said to have held the bookmark to her nose on account of its delicious odour, and soon became comatose, a whole hour elapsing before consciousness was restored. We are assured that on examination the bookmark proved to be saturated with poison, and it has been retained for analysis. Let us hope that this analysis will give us the key to the mystery, because we are at a loss to imagine which, in the arsenal of poisons, might answer to the description.

Epidemic of Cerebro-Spinal Meningitis.

A SHARP outbreak of cerebro-spinal meningitis is reported to have broken out among the troops at Omdurman. The disease is one with which English practitioners do not have many opportunities of becoming familiar, and our knowledge thereof is limited accordingly. We know that it is very contagious, and its occurrence appears to stand in some relationship with insanitary surroundings. Epidemics of the disease are tolerably frequent among French soldiers, and are characterised by a very high mortality, but so far the only means of dealing with it is by general sanitary precautions and measures, and no treatment seems to have any effect in checking its progress when once it has obtained a hold.

Prescriptions and Chemists.

COMPLAINT was recently made in the public press of the difficulty in London of having a prescription made up at a chemists between the hours of nine in the evening and eight in the morning, and we might also add on Bank holidays and Sundays, throughout the day. An instance is given in which a servant visited eighteen different shops before he could get a chemist to dispense the prescription. We should have thought that a chemist would find it worth his while to leave some one always on duty, and who would, in any case, not be above supplying medicine whenever it was required.

Dr. Stevens's Hospital, Dublin.

In our last issue we stated that Mr. Hamilton had resigned the Surgeoncy of this hospital, which he has held so long with such advantage to the institution, and that an election to the vacancy so created was pending. This statement was not altogether correct, inasmuch as Mr. Hamilton still holds the position of Senior Surgeon and performs the duty thereof from day to day, but, as a fact, a fourth surgeon to the hospital was appointed on the day

when we wrote, in the person of Dr. William Steele Haughton, Demonstrator in the School of Physic and Assistant Surgeon to Sir Patrick Dun's Hospital, son of the late Dr. Samuel Haughton, F.T.C.D. Dr. Haughton has had a very distinguished career in the University of Dublin. We hear that there were seven candidates for the position.

The Sex Problem at Southport.

FROM the report of the Medical Officer of Health for Southport we gather that this town is afflictedor shall we say favoured?—with an extraordinary preponderance of females. In a population of rather less than fifty thousand the excess of females over males is upwards of nine thousand. The proportion of males to females in the rural district is only 100 to 103.3, while in the residential quarter of the town the proportion rises to 100 to 196.7, the average of the remaining wards being about 100 to 150. Here is an admirable problem which awaits solution at the hands of some enterprising physiologist who may find therein the data necessary to prove that other factors besides nutrition exert an influence on the differentiation of sex.

The Doctorate in Pharmacy.

It is satisfactory to note that the French Universities which have thought to make a rich harvest by selling doctorates to chemists are at loggerheads The University of Lille has among themselves. entered into competition for a share of the spoil, but the scientists and medical faculty of the University are violently contesting the transaction. Why do not the chemists and druggists, like the spectacle vendors, set up an university for themselves from which they can buy the privilege of calling themselves "doctor," and provide themselves with an illuminated Graduation testimonium and a gorgeous hood and gown?

No Payment for Abortion Advertisements.

So far as the City of London Court can decide the point it is ruled that a newspaper cannot recover the charge for inserting these pernicious advertisements. The Weekly Dispatch sued an advertising agency for £4 10s. for publishing such announcements, and the agency pleaded that, as the advertisements were contra bonos mores the amount could not be recovered. Mr. Registrar Wild, who heard the case, agreed to this, and refused to give a decree, but also refused to give the agency its costs.

ARRANGEMENTS are in progress for holding, in Brussels, an International Congress of Medical Officers of Life Assurance Companies early in September next. Many important subjects will be discussed among which will probably be hereditary disease, dipsomania, and other "habits," and the practicability of a uniform medical code for use in life assurance. Thus does specialism progress in medicine.

THE Italian Government has intimated its intention of taking into its own hands the manufacture of quinine, from which certain factories in Genoa and Milan are making large profits.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

GLASGOW UNIVERSITY.—The following are the names of the candidates for the vacant Chair of Pathology :-Dr. J. Lindsay Steven, formerly pathologist, Glasgow Royal Infirmary; Dr. Robt. McNeil Buchanan, professor Medical Jurisprudence, Anderson's College, Glasgow; Dr. A. Sheridan Delepine, professor of Pathology, Owens College, Manchester; Dr. Charles Workman, pathologist to Glasgow Royal Infirmary, professor of Pathology, St. Mungo's College: Dr. J. Lorran Smith, lecturer on Pathology, Queen's College, Belfast; Dr. Horace Manders, 33, Gloucester Terrace, Hyde Park, London; Dr. Robert Muir, University College, Dundee; Dr. William Russell, 3, Walker Street, Edinburgh. Dr. Sutherland, who has been all along senior assistant to the late professor, is naturally a candidate, and as previously remarked, if the appointment rested with the students Dr. Sutherland would have an easy walk-over. The successful candidate will be expected to enter on his duties on April 25th. Salary £1 100.

University SUMMER SESSION.—It is announced in the University calendar that the Senate have decided to begin the summer session on April 25th. At first it was intended that the Faculty of Arts should not begin before the commencement of May, but as at present arranged, the four Faculties -viz., arts, science, law and medicine—will begin at the same date.

VICTORIA INFIRMARY. - In consequence of the large legacies which have been recently left to the infirmary, the directors have decided and are shortly to extend the Nurses' Home, as they have a large piece of vacant ground on the site on which it is proposed to utilise in the enlargement of the home for the nurses.

AT IT AGAIN.—There is a great deal of talk going on in the city in reference to a recommendation of the House Committee of the new Glasgow Parish Council to erect a hospital at a cost of £200,000. It is understood that the proposal will be fully discussed by the Council at its monthly meeting, which takes place on the 13th At present there are two very large hospitals, viz . Barnhill and the Town's Hospital, and it is not intended that the new hospital should take the place of either of the above. The former of these will, as it is familiarly known, be retained for purely poor-house purposes. "Barnhill Poor-House," the town hospital, is a very large establishment, giving accommodation to at least 1,200 inmates at all times. The scheme at present under consideration includes a small district hospital in the centre of the city. The cry is, "Still they Come." We have previously drawn attention to the number of irons which are in the charitable fires of Glasgow philanthropists, and the likelihood of some, at least, becoming cold, and now seriously ask the question, Where is the money to come from? If the reconstruction of the Royal Infirmary requires £100,000 and two years have now elapsed, and still there is the small sum of £20,000 still wanting, with the committee at variance, if not loggerheads, with each other, and with no immediate start being made, how, then, is this new establishment likely to succeed and be in full swing unless it is intended to tax the population of the city in such a way as to squeeze the necessary sum out of them, or unless the merchant princes of the second city of the empire unite in the spirit of charity and subscribe the sum for the purpose of doing good to their less favoured fellow men and women? This matter will be taken to avizandum.

Correspondence,

We do not hold ourselves responsible for the opinions of our correspondents.

THE CHLOROFORM "BOGEY."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—That there should exist so much misconception as to the conditions affecting the action of chloroform vapour is not surprising when we remember that its employment in surgery is usually to an extent sufficient to produce complete insensibility to the pain of some operation.

As to whether it can be gradually administered during sleep, thus producing a deeper sleep, I have lately had painful personal experience. That I actually did inhale chloroform during my sleep I know by the symptoms I experienced on awakening, and that those symptoms are characteristic of that particular drug I also know from having had personal experience of them after a surgical operation.

I consider myself justified, therefore, in believing the evidence of my senses, especially so since this evidence is strengthened by a corresponding train of symptoms in the person of both the other occupants of my bedroom.

Your remarks upon the bona fides of my statement, and your imputation of an attempt on my part to advertise, are most unjust, and are derogatory both to my character as a medical man and to the profession at large.

I would point out to you that chloroform—which you describe as "a heavy vapour"— is volatile, and that a handkerchief saturated with it and left exposed to the air of a room becomes dry in a few minutes, the air becoming charged with its vapour; that a person sleeping in this room would, provided these conditions were maintained, inhale with the air an amount of chloroform sufficient to render his sleep profound, and that in my case I have no means of knowing the actual quantity that was employed since the handkerchief may have been withdrawn and resaturated several times. I claim that, however impossible it may be to chloroform a subject against his knowledge when awake, yet this may certainly be done while he is asleep.

To your query? "How much chloroform would be required to saturate a handkerchief" (which you answer, "Barely enough to induce unconsciousness in the hands of a skilled anæsthetist") I would reply that two ounces will saturate an ordinary-sized handkerchief, and that half this quantity will certainly render any one insensible that inhales it at close quarters.

I, like doubtless many other practitioners, have repeatedly anæsthetised patients for surgical operation with one ounce of chloroform. This I am prepared to do again, and I think, in conclusion, that it would be more fair on your part to convince yourself by actual experiment of the truth of these observations before attempting to disparage the bona fides of my statement.

Your insinuation that the burglary did not take place will, I trust, be disproved by the ultimate recovery of some of the stolen property.

I am, Sir, yours truly,

NAUNTON MEADOWS.

100, Bow Common, E.

[We have not questioned the bona fides of our correspondent; we have merely contended that he must have been mistaken in his conclusion regarding the chloroform and the handkerchief.—Ed.]

MEDICAL AID ASSOCIATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—I venture to think that if we are anxious to uphold the dignity of the medical profession, we should by every means in our power endeavour to put an end to proceedings which are calculated to bring us into the category of a trade. We all know that competition is very keen, and we all know that advertising is rife even amongst the higher branches of our profession, but I do assert without fear of contradiction that no amount of competition should lead us to countenance acts which savour at all of "touting" for clients. It is of no use shutting our eyes to the fact that in our large towns there exists a system of canvassing for patients either through the agency of Commercial Insurance Companies or through the direct agents of medical men themselves.

By what means this objectionable and unprofessional system is to be put an end to is a question perhaps more for the General Medical Council than for individual members of the profession. At the same time it is very desirable that the extent and scope of the evil should be made known through the columns of the Medical Press and Circular, and it is with a view of eliciting information that I have made these few remarks.

May I say that if the profession generally are desirous of raising the tone and of curing a disease which is rapidly becoming epidemic, the members of it should lose no opportunity of making representations to the General Medical Council?

I am, Sir, yours truly,
A GENERAL PRACTITIONER.

MEDICAL FEES FOR MEDICAL MEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—Very recently my wife has been seriously ill from chest affection. I was also myself not well at the time. My medical friend in attendance, fearing complications

My medical friend in attendance, fearing complications in my wife's case, expressed a wish to see a certain Dublin consultant, Dr. ———. He left Broadstone by the early train, and was able to be back in Dublin early in the evening of the same day. "He charged me thirty guineas for the visit." Such a monstrous fee astonished me. I was prepared to pay all expenses, and to give him something decent beside.

I am anxious to know what would be a fair fee under the circumstances.

I am, Sir, yours truly, JOSEPH O'KELLY, M.D.

[We cannot, of course, be expected to arbitrate as to the value which any practitioner may place on his services, nor as to the "mitigation of damages" which he would agree to in the case of a professional brother in the humble position of a Dispensary Medical Officer, but we do not hesitate to say that a charge of £31 10s. for one day's work under such circumstances would not be justified by either the custom of the profession in Ireland, or consistent with the esprit de corps supposed to prevail. In such a case we imagine that many practitioners would go for the expenses out of pocket and a nominal fee, but there may be others who do not recognise any distinction between a doctor and anyone else as regards liability.—Ed.]

Literature.

WINDYHAUGH. (a)

THE authoress of this story won her spurs, in literature we believe, by a medical novel, "Mona Maclean, Medical Student," she being herself a member of the profession. That work has gone through thirteen editions, truly an all-sufficient further of the most ambitions. literary aspirant for further efforts in this direction. Whether "Windyhaugh" be destined to such an achievement time alone can decide. The initial volume was breezy and full of sustained action from cover to cover. It, moreover, traversed a comparatively untrodden field. which none but a writer conversant with the by paths of medicine could have incorporated. The present novel, however, has nothing of a medical nature about it, if we except the description of a morphomaniac, the heroine's father to wit, his passions, and his inevitable end. It is the story of a motherless girl to whom we are introduced at the age of seven, perched on the top of a cask of sugar in a grocer's shop, arguing with the proprietor in somewhat precocious fashion on the subject of religion. This child is under the care of her grandmother at a quaint old homestead called "Windyhaugh," which we take to be somewhere near, if not actually in, Scotland, from the names of the characters introduced, and the austerity of certain religious notions. The child's father, Mr. Galbraith, is a mystery throughout the piece, the one thing certain about him being that he is an inveterate gambler at Monte Carlo, and like the majority of that ilk,

(a) "Windyhaugh." A Novel. By Graham Travers (Margaret G. Todd, M.D.). Edinburgh and London: Blackwood and Sons. Pp. 446. Price 6s.

is very flush at times with the mammon of unrighteousness and spends as recklessly as he receives: whilst at others he is penniless, runs up bills he is unable to meet, and borrows of such friends as are foolish enough to

yield to his importunities.

Wilhelmina's grandmother inculcates her own very narrow views of religion and of the world generally into the child's mind at this early period of her life, and throughout the remainder of it these struggle alternately with the broader views of womanhood, the sobering influence of time, and her own higher nature, in which the reader becomes immensely interested. In her case the course of love runs very smoothly, but on the day of her marriage she discovers a letter in returning from church which induces her to leave her husband straightaway, and for the next four years she battles alone with the world, educates herself in the classics and higher forms of mental culture; meets her husband occasionally, when the old spark of love has almost died out, and, finally, as is the case in most novels, they both find themselves madly in love with one another, and "live together everlastingly happy." How all this is brought about we must leave the reader to trace. There are some fine pieces of character writing in the book, and if the story does not prove so attractive as "Mona Maclean, Medical Student," it at least possesses merits above the common order of novels.

Medical Rews.

More Female Health Inspectors.

FOUR women health inspectors have been selected by the Birmingham Health Committee out of some ninety applicants. The new officers commence their duties on April 10th, and their inspection will be confined mainly to the poor districts in and about the centre of the city.

Puerperal Fever.

THE Medical Officer of Health for Bristol has caused to be sent to all medical practitioners the following note: - " A Committee of the Royal College of Physicians of London has recently endorsed the view that the expression 'Puerperal Fever' should be taken to include Septicæmia, Pyæmia, Septic Peritonitis, Septic Metritis, and other acute Septic Inflammations in the Pelvis, occurring as the direct result of childbirth." The Council of the Obstetrical Society of London suggests the following inclusive definition of the term "Puerperal Fever." That is:—"Septicemia and Pyæmia, including Peritonitis, and all cases of acute Pelvic Inflammation occurring in connection with childbirth."

The School of Anatomy.

AT a meeting of the St. Saviour's (Southwark) Guardians, last week, it was resolved to inquire of the authorities of the School of Anatomy how the bodies sent to them by the guardians were ultimately disposed of, and whether their use was strictly confined to medical and surgical research. Mr. Upfield, who moved the resolution, said he had it on very good authority that portions of human bodies were used in a disgusting manner by many medical students. It was their duty as a board to see that the bodies they sent were reverently treated and given a decent and a Christian burial when they had served their legitimate purpose. The Rev. G. W. Keesey said he had spent some time in dissecting-rooms, and was satisfied that bodies were not always treated as reverently as they should be. The Rev. J. W. Horsley said he had dissected every kind of body, from a worm to that of a human being, but he did not agree with the Rev. Mr. Keesey's account of what took place in the dissecting-room. In reply to a member, the Rev. G. W. Keesey said that medical students took portions of bodies home with them. He was not satisfied that the present precautions were adequate.

Mortality in Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Bombay 150, Madras 37, Paris 26, Brussels 27, Amsterdam 16, Rotterdam 21, The Hague 19, Copen-

hagen 23, Stockholm 20, Christiania 14, St. Petersburg 26, Moscow 28, Berlin 18, Hamburg 18, Dresden 20, Breslau 24, Munich 25, Vienna 22, Prague 32, Buda Pesth 28, Trieste 30, Rome 24, Turin (10 days) 20, Venice 30, New York (including Brooklyn) 19, Philadelphia 23.

Vital Statisfics.

THE deaths registered last week in thirty-six great towns of United Kingdom corresponded to an annual rate of 23 1 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year.

Birkenhead 23, Birmingham 22, Blackburn 25, Bolton 22, Bradford 21, Brighton 21, Bristol 18, Burnley 24, Cardiff 13, Croydon 19, Derby 22, Dublin 31, Edinburgh 20, Glasgow 23, Gateshead 19, Halifax 22, Huddersfield 16, Hull 19, Leeds 25, Leicester 19, Liverpool 26, London 23, Manchester 33, Newcastle-on-Tyne 19, Norwich 20, Nottingham 20, Oldham 32, Plymouth 27, Portsmouth 20, Preston 19, Salford 28, Sheffield 23, Sunderland 21, Swansea 23, West Ham 17, Wolverhampton 29. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1.7 in Manchester, and 2.3 in West Ham; from scarlet fever, 2.0 in Derby from whooping-cough, 1.4 in Cardiff, 1.8 in Birkenhead, and 2.1 in Plymouth; and from "fever," 1.8 in Wolverhampton. In none of the large towns did the death-rate from diarrhea reach 10 per 1,000. The 84 deaths from diphtheria included 37 in London, 8 in Sheffield, 7 in Leeds, 6 in Leicester, and 3 in Portsmouth. No death from small-pox was registered in any part of the United Kingdom.

A VERY appreciative sketch of the late Professor Kanthack appears in the current number of the Eagle, the magazine supported by members of St. John's College, Cambridge.

PASS LISTS.

Victoria University, Manchester.

THE following candidates passed the respective examinations during the March sittings of the Court;—

Anatomy and Physiology—Second Examination.

Anatomy and Physiology—Second Examination.

John Acomb, Yorkshire; F. H. S. Ashworth, Owens; Herbert Bates, University: J. L. Beddoes, University; H. M. Birkett, Yorkshire; J. W. H. Brown, Yorkshire; Fred Bullough, Owens; W. H. Canter, Yorkshire; J. B. Cook, Owens; J. F. Corson, Owens; J. M. Cort, Owens; J. B. Cook, Owens; Tom Eastham, Owens; J. E. Floyd, Owens; J. A. C. Forsyth, Yorkshire; H. E. Fox, Owens; G. W. Gelderd, University; D. G. Gellatly, Owens; V. J. Glover, University; P. H. Green. Owens; J. W. Greenwood, Owens; Frederick Griffith, University; W. S. Holmes, Owens; W. L. Maccormac, Iorkshire; Charles Mackey, Owens: C. T. Matthews, Yorkshire; J. S. W. Nuttall, University: T. F. Pugh, University; Arthur Richmond, Owens; Edwin Saville, Yorkshire; F. R. Sawdon, Owens; G. H. Shaw, Owens; Robert Smailes, Yorkshire: H. G. Tansley, Owens; H. C. Waterhouse, Owens; Alwyn Wharton, Owens; B. M. Wilson, Owens; F. P. Wilson, University; J. G. Woolham, Owens.

Materia Medica and Pharmacy.

C. W. S. Boggs, Yorkshire; S. B. Brentnall, Owens; J. C. Caley, Yorkshire; A. C. Clarke, Owens; A. M. Deane, Yorkshire; J. A. C. Forsyth, Yorkshire; P. T. Harding, Owens; J. L. Hawkes, University; F. W. Hayes, Yorkshire; G. B. Heath, Owens; Marshall Hooper, Owens; S. B. Mehta, Owens; J. B. O'Donoghue, Yorkshire; W. P. Potts, Yorkshire; S. W. Swindells, Owens; M. G. L. Walker, Yorkshire; F. W. B. Young, Yorkshire.

University Scholarship.

M'Fall, University; Thomas O'Neill, Owens; J. A. Reed, Yorkshire; Graham Renshaw, Owens; W. H. Richardson, Owens; O. H. Woodcock, Owens.

The following were awarded honours:—Second Class: John Craig, Owens; W. H. Richardson, Owens; O. H. Woodcock, Owens,

Craig, Owens;

Aotices to Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves " Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS .- Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before the type is broken up.

THE LISTERIAN RITUAL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

To the Editor of the MEDICAL PRESS AND CHULLE.

SIR,—It is amazing that Dr. Bantock's critics cannot see his simple and irrefutable answer argument. The Listerian ritual cannot be in any way advantageous to surgical operations if he can do as well without it as others can do with it. To claim sulphureous acid as a part of the ritual is as reasonable on the part of Mr. Bowreman Jessett as if he claimed the sun and the moon.

I am, &c.,

LAWSON TAIT.

195 Newhall Street, Birmingham, March 28th, 1899.

J. J. Smith (Ripon).—You are quite right in supposing that the pollution of streams goes on practically unchecked in many parts of the United Kingdom. The "adoptive" Part III. of the Public Health Amendment Act, 1890, as concerns rural authorities (in London it is compulsory, directs as to pollution of streams by solid refuse: "It is forbidden to throw or place in any watercourse within any district in which this part of the Act is adopted, any cinders, sahes, bricks, stones, rubbish, dust, filth, or other matter which is likely to cause annoyance." This is fairly comprehensive, but the difficulty is to get rural authorities to listen to the wooing of the permissive siren. Let our correspondent try his hand in his own district.

CANDOUR.

PATIENT (who has just had his eye operated upon): "Doctor, it seems to me ten guineas is a high price to charge for that job. It didn't take you ten seconds." Eminent Oculist: "My dear friend, in learning to perform that operation in ten seconds I have spoiled more than two bushels of such eyes as yours"

THE Word "Bronchitis," according to Dr. Samuel Gee, was invented in 1814 by Dr. Charles Badham, F.R.C.P.L. It superseded the old phrase, "pulmonary catarrh."—C. and D.

the old phrase, "pulmonary catarrh."—C. and D.

QUEERNS.—If you examine a shred of mucus from the urine, and find gonococci, the patient is suffering from chronic gonorrhea, and is infective. He is therefore unfit to marry, and if he be a man of good principle he would not wish to contract any union under such ill-starred auspices. The remote results of gonorrhea are disastrous in the extreme, and it is better that the question of gonococci should be faced in the consulting room than in the operating theatre or the Divorce Court.

RUSTICUS (West Country).—To treat a patient suffering from appendicitis in the state you describe by purgatives, enemata, and sinapisms, amounts virtually to manslaughter With reasonable law against unqualified medical practice, an offence of the kind would meet with speedy retribution. You did your du y in declining further treatment without operation. It would be well to send a full statement of the facts to Dr. Bateman, the secretary of the Medical Defence Union.

Medical Defence Union.

Dr. Ferrals.—For an answer to your query as to erysipelas you may be referred to a formula recently published in the Medical Brief. A drachm of sulphate of iron is triturated finely with a pound of native pulverised chalk, and made into a soft paste with lard. This ointment is spread a quarter of an inch thick on calico, and applied to the erysipelatous surface. It is claimed that the application will cure any erysipelas within twenty-four hours, but we have no personal experience of its use.

Meetings of the Societies and Tectures.

WEDNESDAY, APRIL 5TH.

OBSTETRICAL SOCIETY OF LONDON.—8. p.m. Specimens will be shown by Dr. A. Routh, Dr. Lea, Dr. McKerron, and others. Papers: Dr. W. S. A. Griffith and Dr. T. W. Eden: Notes of a Case of Puerperal Eclampsia, with a description of a Five Weeks' Ovum removed in a Subsequent Pregnancy.—Dr. Lewers: A Case of Persistent Mento-posterior Position of the Face in which the Child was delivered alive by the Axis-traction Forceps.

THURSDAY, APRIL 6TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).-8.30 p.m. Clinical Evening.

FRIDAY, APRIL 7TH.

FRIDAY, APRIL 7TH.

WEST KENT MEDICO-CHIEURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.)—8.45 p.m. Discussion on Tuberculosis, with special reference to Treatment (opened by Dr. G. Heron), Short Papers Dr. M. Dockrell (President): Tuberculosis of the Stain.—Mr. E. Clarke: Tuberculosis of the Eye—Mr. M. Collier: Tuberculosis of the Nose and Throat.

WEST LONDON MEDICO-CHRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8.30 p.m. Dr. S. T. Pruen: The Open-air Treatment of Tuberculosis.—Mr. H. J. Paterson: The Use of Gas in General Surkery.

LARYNGOLOGICAL SOCIETY OF LONDON (20) Hanover Square, W.).—5 p.m. Cases and specimens will be shown by Dr. St. Clair Thompson, Dr. Potter, Dr. Donelan, Dr. Lack, Dr. Kelson, Mr. Parker, Mr. De Santi, Mr. Cheatle, and others.

Dacancies.

Birmingham and Midland Ear and Throat Hospital, Edmund Street Birmingham.—House Surgeon for six months. Salary at the rate of £42 per annum, with board, lodging, and washing.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £75 per annum, with board and lodging, but no alcoholic

liquors.

liquors.

County Asylum, Chester.—Junior Assistant Medical Officer, unmarried. Salary commencing at £120 per annum, with board (no liquors), lodging, and washing. Also Medical Officer to act principally as Pathologist. Salary £150 per annum, with board (no liquors), lodging, and washing.

County Asylum, Shrewsbury.—Junior Assistant Resident Medical Officer for four years Salary commencing at £120 per annum (and £8 in lieu of beer, &c.), with board, lodging, and washing. Applications to the Medical Superintendent of the Asylum.

East Suffolk and Ipswich Hospital, Thoro'fare, Ipswich.—Second House Surgeon for one year. Salary £60 per annum, with board, lodging, and washing, and washing, and washing.

lodging, and washing. Claybury, Woodford Bridge, Essex.—
Junior Assistant Medical Officer (male). Salary £150 per
annum, with board, furnished apartments, and washing. Applications to the Clerk of the Asylums Committee, 6, Waterloo
Place, S. W.

Place, S. W.

North Edding Asylum, Clifton, York.—Junior Assistant Medical
Officer. Salary £100, rising to £150, with board, lodging, washing, and attendance.

Queen Charlotte's Lying-in Hospital, Marylebone Road, London.—

Resident Medical Officer for four months. Salary at the rate of

Resident medical Omeer for four months. Salary at the rate of £60 per annum, with board and residence.

Scarborough Hospital and Dispensary. - Senior and Junior Resident House Surgeons. The Senior for twelve months at a salary of £60 per annum, with board and lodging, and the Junior for six months at a salary at the rate of £50 per annum, with board and lodging.

Appointments.

BEALE, PEYTON, T. B., F.R.C S.Eng., Surgeon to in-patients of the Great Northern Central Hospital, Holloway.

BURGESS, A. H., M.B., Ch.B.Vict., M.Sc., M.E.C.S., Senior Assistant Resident Medical Officer to the Crumpsall Workhouse of the Township of Manchester.

CARGILL, L. VERNON, F.R.C.S.Eng., Assistant Ophthalmic Surgeon to King's College Hospital, London.

JEPHCOTT, C., M.A., M.B., B.C.Camb., M.R.C.S., L.R.C.P.Lond., House Physician to Guy's Hospital, London.

KAY, J. G., M.B. C., M.Edin., Medical Officer to the Trellech Sanitary District of the Monmouth Union.

KELYNACK, T. N., M.D.Vict., M.E.C.P.Lond., Pathological Registrar to the Manchester Royal Infirmary,

MALINS, HERBERT, B.A.OXON, M.B.C.M.Edin., Second Assistant Medical Officer to the St. Marylebone Theory, North Kensington.

MALINS, HERBERT, B.A.OXON, M.B.C.M.Edin., Second Assistant Medical Officer to the St. Marylebone Infirmary, North Kensington.

MATHIAS, R., M.B.Camb., LR.C.P.Lond., M.B.C.S., Medical Officer for the Pentyrch Sanitary District by the Cardiff Board of Guardians,

MOGRHELD, R. L., M B., C.M.Edin., Medical Officer to the First Sanitary District and the Workhouse of the Bridge Union.

Beynolds, Francis Mortimes, M.B., C.M.Edin., Medical Officer to the Newton Poppleford District, Exeter.

Right, Hugh' Mallinson, M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond., Surgical Registrar to the London Hospital, Whitechapel.

Robinson, B., L.B.C.P.Lond., M.R.C.S., Medical Officer to the Rocester Sanitary District of the Uttoxeter Union.

Slongert, Harby Fayner, L.R.C.P.Irel., M.R.C.S., Surgeon on the Unattached List of the Victorian Naval Brigade, Department of Defence, Victoria, Australia.

Tothill, F. C., M.B., C. M.Edin., Medical Officer of Health to the Staines Urban District.

Births.

COLLINS.—March 28th, at the Red House, Sawbridgeworth, the wife of Ethelbert Collins, L.R.C.P.Lond., M.R.C.S., of a daughter.

Cook.—March 29th, at 22, Newport Road, Cardiff, the wife of Herbert G. Cook, M.D., F.R.C.S., of a daughter (stillborn).

Wilker.—On March 27th, at Dawson Place, Pembridge Square, the wife of Basil Woodd Walker, M.D., of a daughter.

Marriages.

ABBOT-ANDERSON-SHAW. March 29th, at St. John's Church, Nottinghill, W., M. Abbot-Anderson. M.B., B.S., of 37 Wimpole Street, London, W., to Maude, widow of the late Jas. Robert Shaw of Leeds.

Shaw of Leeds.

CARDALE - DIR-DEN.—March 28th, at the Catholic Apestolic Church, Chelsea, Henry Jasper Cardale, M.B., C.M., eldests nof Vice Admiral Cardale, of Stoke, to Bruce, third daughter of J. S. Dib-den of Toller, Dorset.

Kember.—Hunt.—March 28th, at the Cathedral, Shanghai, Arthur T. Kember, F.R C.S.E., eldest son of the Rev. T. Kember of Palamcotta, to Alice, second daughter of Richard Hunt of Hampstead.

Deaths.

COKE.—On March 22nd, at his residence, Glen Lea, Southampton, George Richards Cooke, M.R.C.S., L.S.A., aged 61 year..
WALLICH,—March 30th, Surgeon Major G. C. Wallich M.D., H.M.I.A., retired list, aged 83 years.

Perfection of Ciquid Extract of Malt

Although Liquid, BYNIN possesses the same diastasic

power as the ordinary thick Extract.

BYNIN mixes readily with milk, helping Being Ciquid, complete digestion, and preventing the formation of large clots of casein.

As Liquid,

BYNIN is far more pleasant to take, more easily mixed with other food, and more quickly assimilated than the thick Extract.

is a boon to Rursing Mothers, Bunin replacing Alcoholic drinks.

DIASTASIC ACTIVITY.—"We find that at a temperature of 100°F. one ounce will digest perfectly one pound of starch. This is a most satisfactory result, and, coupled with the fluidity and pleasant flavour, renders this preparation a most valuable one."—The Lancet.

Allen & Hanburys Ltd., Plough Court, London.

PEPSINA LIQUIDA

SCHACHT

A Perfect Pensing of Exceptional & Invarying Activity.

This Fluid Pepsine is produced of <u>standardized</u> digestive strength; and is a most important remedial agent in the treatment of indigestion, infantile Diarrhœa, and all Diseases arising from imperfect Nutrition.

The physical characters of **Schacht's Fluid Pepsine** are those of pure gastric juice. It is a clear liquid of agreeable appearance, without appreciable taste, smell or colour, and entirely palatable. But its chief feature is the extraordinary digestive power that it possesses, and which is practically without limit. After some experience it is believed that all ordinary requirements will be satisfied if this pepsine be adjusted to such a strength that a fluid drachm shall be capable of digesting one thousand grains of cooked egg-albumen. This standard, therefore, is adhered to; and it is guaranteed that every teaspoonful of of **Schacht's Liquid Pepsine**, when tested by the official B.P. process, shall give the same result, namely, the solution of fully (more than) 1,000 grain of albumen. Every physician who desires efficient aid in combating mal-nutrition is earnestly invited to make a trial for himself.

Although Schacht's Pepsine may be well prescribed in combination with many other medicines, it is respectfully suggested that it be given independently with the food; and also that it be ordered in the original bottles (the 4-oz. size retails at 2s. 6d.), when the patient will be safe against counterfeit or substitution.

The adult dose is a teaspoonful or less, as may be directed, with each meat meal. On account of its agreeable flavour children take it readily, and in several of the wasting diseases to which they are liable, as well as in the diarrhosa of infants, there is no agent of such indisputable value. Ten to fifteen drops of the pepsine should be given, by itself, every time the child is fed.

We prepare also

SCHACHT'S PEPSINA LIQ. c BISMUTHO.

Each drachm contains in a concentrated form, besides the fluid pepsine, a full dose of Schacht's Liquor Bismuthi. An elegant and successful combination. Dose: One drachm. For dispensing, $\frac{1}{2}$ -lb. and 1-lb. bottles.

N.B.—Peps. Liq. c. Bismutho Co. contains in addition, one gr. of soluble Euonymin in sach drachm.

SCHACHT'S PEPSINA LIQ. c EUONYMIN.

Each drachm contains one grain of soluble Euonymin. Dose: One drachm. For dispensing, $\frac{1}{2}$ -lb. and 1-lb. bottles.

The Formulæ are given on every label.

In 4-oz., $\frac{1}{2}$ -lb., and 1-lb. Bottles.

To be obtained of all the Wholesale Houses; or direct from

GILES, SCHACHT & Co., CLIFTON, BRISTOL.

'SAXIN'

Has been aptly termed the "Sweetest thing on earth." It is about 600 times sweeter than sugar and more delicate in flavour. 'Saxin' undergoes no change in the system, and may be safely prescribed in all cases where sugar is harmful.

'8axin,' 1/4 gr., is supplied in bottles of 100 and 200, at 7d. and 1s. 1d. per bottle.

'EMOL-KELEET'

Is a natural powder, containing a large proportion of native silicates. It has proved successful for drying weeping surfaces when all other powders have failed. Its soft, silky texture, soothing influence and other physical qualities enhance its healing action.

'Emol-Keleet' is supplied in neat metal boxes, at 9d. per box.

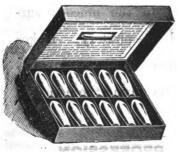

BURROUGHS WELLCOME AND CO., LONDON AND SYDNEY.

FOR THE SEQUELÆ OF INFLUENZA.

ANGIER'S PETROLEUM EMULSION is indicated in the catarrhal conditions, whether Tonsillar, Bronchial, or Intestinal, which so commonly follow the more acute stage of Influenza. It is particularly efficacious in relieving the harsh and irritating cough, while its antiseptic action in the alimentary canal and its peculiar soothing effect upon the gastrointestinal mucous membrane make it of great value in the treatment of the intestinal disturbance.

Furthermore, its effect in promoting a healthy secretive action, in stimulating nervous and vascular supplies to the mucous membranes, and in favouring a normal moisture in the mucous surfaces, both digestive and respiratory, makes Angier's Petroleum Emulsion fulfil most completely the needs of the system during the period of convalescence.

FREE SAMPLES TO THE MEDICAL PROFESSION.

when prescribing be careful to specify ANGIER'S Emulsion; otherwise some disappointing imitations made with ordinary petroleum may be substituted.

THE ANGIER CHEMICAL CO., LTD.,

Original Communications.

SOME CASES OF PERFORATING GASTRIC ULCER.

By THOMAS MYLES, M.D., F.R.C.S.I., Vice-President Royal College of Surgeons, Ireland; Surgeon to the Richmond Hospital.

In no branch of abdominal surgery has the departure from old traditions been more pronounced, and in none have the successes been more brilliant than in that to which I shall refer to-night.

So many points of interest spring before one's mind in connection with this subject that there is a difficulty in making a selection, without omitting what may be vitally important. I will first refer briefly to the cases that have come under my notice, and then discuss necessarily in a very cursory manner a few of the more important points that are still controversial. Some months ago I was asked by my friends, Sir Francis Cruise and Dr. Moran, to see with them a wentleman with the following history.

a gentleman with the following history.

Early on that day, when at his office, he had been seized with violent abdominal pain and vomiting. My friend, Dr. Moran, saw him, and on examination found him suffering from an umbilical hernia—tense, hard and tender. This hernia Dr. Moran reduced, and the patient expressed himself as feeling somewhat relieved. He was then put in a cab and driven

home.

Some little time later on the same day the vomiting recommenced, and the patient complained of unendurable pain above the umbilicus in the middle line of abdomen.

Sir Francis Cruise who had previously treated him for gouty affections, was called into consultation, and during his examination the patient began to vomit black tarry matter, evidently blood acted on by the gastric juice. At this stage it was resolved surgical advice should be had, and I was sent for as detailed above.

I saw the patient at 8 p.m., he was a thin. spare, man of ascitic type, æt. 70, with an expression of great suffering in his features.

His legs were drawn up, his abdomen slightly distended, was rigid as a board, his breathing shallow and hurried, the slightest touch in the abdomen caused great suffering, and on percussion the area of liver dulness was replaced by one of resonance.

At the umbilicus was still felt a decided fulness, as if the hernia had perhaps partially recurred. He had all the aspect of a man rapidly sinking in a state of collapse, and it was evident that if any surgical measures were to be undertaken, there was no time for delay. I may add here that though, of course, we all diagnosed perforation of the stomach, we were rather inclined to attribute it to sloughing of portion of the stomach wall previously involved in the hernia, rather than to a perforating ulcer of the ordinary type.

The patient's relatives seeing his collapsed condition, and being told frankly that the operation held out no great hopes of saving him, were unwilling to subject him to what seemed useless and additional

suffering, and I confess with this feeling I largely sympathised. On laying the case fairly and squarely before the patient, to our great surprise, he at once elected to be operated on, saying with both wisdom and resolution that he would rather die at once on the table than prolong his present azony till the inevitable end came.

As the accommodation in his present quarters was totally inadequate for such a grave operation, it was decided to remove him to the Richmond Hospital close by and operate there. This was done, and all preparations being duly completed, ether was administered by our then house surgeon, Dr. Louis Robinson. Dr. Harvey, assistant surgeon to the hospital, assisted me at the operation, which was witnessed by Sir Francis Cruise and Dr. Moran, and the resident staff.

An incision was made in the middle line so as to expose the umbilical hernia, exploration of this showed that the hernia was reduced, but the sac was very thick, and contained some fatty masses in its outer surface which gave me the impression that the hernia had partially recurred, or had been incompletely reduced. Coils of intestine now faked with lemb core into rion and a little now flaked with lymph came into view, and a little later fluid, evidently from within the bowel somewhere, trickled down from above. The wound was therefore enlarged upwards, and a very slight search brought the perforation into view. It was in the anterior stomach wall some two inches from pylorus, and was about inch long extending vertically from above There was no evidence of any constriction around it to indicate that it had been involved in a hernia, so this hypothesis had to be abandoned. Further examination showed a good deal of thickness and hardness about the pylorus, and I at once suspected the possibility of malignant disease. A probe was passed into the opening and thence through the pylorus. It undoubtedly gave me the impression that the case was complicated by a pyloric stricture, and I at once proposed to establish a gastro-jejunal anastomosis. Sir Francis Cruise, however, in answer to my inquiry as to the patient's strength being sufficient that the delicities of the sufficient that the cient to stand this additional procedure, informed me that if the operation was not promptly completed the patient would die on the table. I resolved, therefore, to close the wound in the stomach, and postponed any further measures until the patient had rallied. The edges of the little wound were therefore carefully resected, and closed with a double row of silk sutures, the first continuous, the second interrupted. As the patient was now practically pulseless and very cold thorough cleansing of the peritoneum was impossible, and it was resolved to douche the abdominal cavity with a hot saline solution. This was done while the sutures were being passed in the abdominal wall, and had a very stimulating effect, the patient at once rallying. A small gauze drain was carried down to the line of sutures in stomach as it was felt that the rapidity with which the operation details had been carried out, prevented us placing absolute confidence in the completeness and perman-The patient having been ance of the suturing. carried back to bed, vigorous methods were adopted to rouse his dormant energies. His limbs were completely enveloped in cotton wool, hot blankets were wrapped around him, hypodermics of strychnine and atropine, and rectal injections were administered, the end of the bed raised about a foot above the level of the head, to encourage the central blood supply, and hot saline solutions with a transfusion outfit were kept handy, to be available in case of emergency.

For several hours he hovered between life and death, but gradually his latent energy began to manifest itself, the pulse at the wrist again became perceptible, the sufferer became warmer, and he gradually recovered consciousness. moment until the fourteenth day, he never looked back. Nursed with the most assiduous care under the directions of Miss McDonnell, our Lady Superintendent, he recovered with a rapidity that I have never seen equalled by one of his age before. On the fourteenth day, when I visited him, a serious change had taken place. He was cold and blanched, pulse very rapid and fluttering, breathing hurried, complained of great thirst, and said he felt himself dying. Inquiry elicited the fact that during the act of defecation copious hemorrhage had taken place from the bowels, and two pans filled with fluid blood bore testimony to the statement. While speaking to him he complained of again wanting to stool, and then and there he passed another panful of blood. Needless to say, this was a terrible blow to us, just as we had piloted him, as we thought, through all his dangers, was his barque foundering within sight of land? A hurried consultation with my friends. Sir Francis Cruise and Dr. Moran, was held, and though it was obvious that to administer an anæsthetic and thoroughly explore the rectum was out of the question, we thought it might be possible without undue shock to find the bleeding spot and control it.

A large soap and water enema was given at once, the rectum well emptied, and then just inside the anal margin a ring of swollen, deeply congested piles were seen. A little cocaine solution was swabbed over them, and then a tampon of cotton wool soaked in Friar's balsam was inserted and kept in place with a

pad and bandage.

This had the desired effect, no more bleeding occurred, and though convalescence was seriously retarded by this untoward complication the patient some six weeks after the operation was driven in a pneumatic-tyred carriage to Kingstown, where the fresh air and sea breezes soon restored him to his pristine vigour. He is now, I am glad to say, back again at his business as a director of one of the largest commercial enterprises in the City. I have given the details of this case at some length, partly because it was far the most interesting of all those I have met, but also because it was the most recent, and, therefore, the impressions derived from it were the strongest. The total number of cases I have operated on up to the present, in which the diagnosis of perforating gastric ulcer was made before and verified at the operation, is four.

Of these, three occurred in females and one in a male. Of the three in women two died, one some twelve hours after the operation, and the other exhausted by prolonged suppuration and leakage through a gastric fistula.

A few brief notes of these I will lay before the

Mary A., æt. 19, a servant in the Young Women's Christian Association, Harcourt Street, was attacked suddenly with violent abdominal pain, vomiting, and collapse. No hæmorrhage; called to see her, I at once diagnosed perforation, and had her removed to the Richmond Hospital. She was seen by my colleagues in consultation, and an operation urged upon her—this she declined. Two days later she was much better, and felt convinced she had been wiser than

her medical advisers. She was seen from time to time by my colleagues and complained only of a feeling of fulness in the epigastric area, and some tenderness on pressure. She was living on a fluid diet, and had no vomiting. Some six weeks after her admis-sion to hospital she suddenly developed acute pain in the abdomen, a swelling formed in the left side of epigastrium, dull on percussion, with edema of skin over it. It was obvious an abscess was forming. At the urgent solicitation of her friends she eonsented to the abscess being opened, but no further operation was to be attempted. As a matter of fact nothing else could be done. A large abscess was evacuated, but the thick layer of lymph which covered everything made it impossible to recognise any of the viscera, or to find the opening of the stomach.

The cavity was douched out and drained, and for a time we hoped she would recover, but she gradually sank and died of exhaustion.

Had this girl consented to the operation proposed within a few hours of the onset of her illness, in all probability her life would have been saved.

The other two cases may be dealt with briefly. One was a woman, æt. about 30, in whom perforation had taken place some days before admission to hospital. She was emaciated to an extreme degree, and a large collection of fluid could be easily recognised in the abdomen. In cutting into this quantities of half digested potatoes and the liquid contents of the stomach were discovered, but she never rallied, and died very soon after the operation.

The fourth case was more interesting. Patient, a married lady, æt. 32, was seized with violent pains in the abdomen, vomiting and collapse; no bleeding. When I saw her the collapse was so pronounced that operation was out of the question. Heat was applied to the epigastrium, rectal injections of alcohol, and a small hypodermic of morphia given later. Twentyfour hours later pain had subsided, but there was one spot very tender, exactly in the middle line. Operation proposed and declined, patient alleging, with a certain amount of justification for her belief, that she felt certain she would die on the table. Five days later a small abscess had formed. This was explored with a hypodermic syringe, and the diagnosis being thus verified, local anæsthesia was produced with the ether spray, and the abscess opened with a tenotome. About an ounce or so of thick pus evacuated and a small drainage tube inserted. Though I naturally gave a very unfavourable prognosis, the patient recovered rapidly, and is alive and well to-day

So far for the cases in which the diagnosis of perforation was made and verified by operation.

But in common with all surgeons of any experience, I have diagnosed perforation of the stomach which did not exist. In one case in which I was mistaken, a remarkably accurate diagnosis had been made by a much younger man, Dr. Grundy, at one time house surgeon at the Mater Hospital. He sent a patient into the Richmond Hospital in whom he had diagnosed perforation of the bile duct, but which I confess I believed to be a perforation of the stomach. Laparotomy was performed. A biliary abscess was opened and drained, but it was found impossible to discover the seat of perforation. The patient gradually sank and died of exhaustion. The autopsy

was made by my friend Dr. Woods, who discovered a perforation of the cystic duct.

In another case in which perforation of the stomach was diagnosed, I found that organ apparently perfectly healthy, and nothing but a localised

collection of peritoneal fluid.

My friend Dr. Chance some time ago operated on a similar case, in which also nothing abnormal could be discovered.

Quite recently, Dr. Conway Dwyer exhibited a

Digitized by Google

another scientific gathering a patient on whom he had operated for perforation of the stomach, but exploration showed that the lesion was an acute strangulation of a coil of the jejunum, which he resected with the most brilliant success. I mention these cases because in these, as in all other abdominal cases, the liability to error in diagnosis is ever present. It is because of this inherent weakness in the power of diagnosis that one is compelled to question the accuracy of the statement so often made at the last meeting of the British Medical Association that recovery frequently takes place spontaneously after perforation.

I confess myself unable to accept such a result as probable, or even possible, except in a very minute

proportion of cases.

Should a perforation occur, of the pinhole type, in an absolutely empty stomach, no extravasation of the contents need take place, and the little opening may

soon be shut off by exudation.

The experience of physicians, pathologists, and operators is entirely opposed to the belief in the frequency of such a fortunate combination of circumstances. In this connection, Hume's theory miracles seems to be applicable.

Is it not more probable that the diagnosis was erroneous than that phenomena opposed to all pathological experience have occurred? Forgive me if I appear to labour this point, but it is vital and

.eggential

If spontaneous recovery is at all within the limits of probability, operation might very well be at least delayed. I venture to say, however, that very few men, even of those with the most profound belief in the efficacy of drugs and the powers of human resistance, would take the responsibility on themselves of recommending a patient in a case of supposed perforation not to submit to operation, but to trust to the vis medicatrix uature. Surgical experience, now fairly extensive in this subject, has shown that the earlier the operation is undertaken, other factors being appropriate, the better the chance of success.

If the abdomen is opened before exudation of lymph has taken place, the opening is generally easily found. If twenty-four hours have elapsed in an average patient, the matting together of all the organs, and their envelopment in a thick layer of lymph, renders it practically impossible. In such a case death from exhaustion is almost, though not

absolutely, inevitable.

Again, in approaching a case of perforation the surgeon must remember that the operation may be very easy or very difficult. If the opening is in front and the operation is promptly undertaken, the work will not be difficult. If the opening is behind, or the operation delayed, it may tax all the surgeon's resources and end in failure and disappointment. Two points in the technique I would like to refer to. 1st. The use of the douche, and 2ndly, the use of a drain. It is urged against the use of the douche that it may convey infecting particles to areas as yet uninfected, and thus prove the cause of a general septic peritonitis. Per contra, it is urged that no amount of morping can ever completely cleanse the peritoneum, and Mr. Treves, quite recently, has drawn attention to the fatal injury that may be done to its smooth, glossy and absorbent surface by violence applied to it under a mistaken idea of its function and limitations.

I must confess I am rather against the mopping plan, and favour the thorough douching. If the nozzle of the douche is carried low down into the pelvis first and later into the flanks the stream of warm water rushing out through the wound under pressure will carry practically everything with it. It is will not lose time in discussing the hypothesis of a may be necessary here and there to assist this process, hernia of the lung, for the case is one of gaseous by wiping away all adherent particles, but it is only

the stomach contents that need to be wiped away, the lymph exudation may well be left alone unless there is reason to believe that it is already a centre of decomposition and infection.

Lastly, I believe these cases ought to be drained until the temperature is normal, and until the seat of perforation is shut off from the general cavity of the peritoneum. The tissues around the seat of ulcera-tion are generally unhealthy, even the most expert operator may have his doubts as to the durability of

his suturing under such circumstances.

I fear I can hardly claim to have laid anything new before you, but the subject though not novel is not without interest; it deals with a fairly common condition, and therefore appeals to physicians and surgeons alike.

When we remember that even 20 years ago such operations as those I have outlined to you if suggested by an operator would have been regarded as the dream of a lunatic, one cannot help feeling both proud and

hopeful of our art.

The modern operation of laparotomy, simple as it seems to-day, has only reached its present position through the combined labours, trials, experiments, and disappointments of the greatest minds of our age. Though it is not given to all of us to be originators of great ideas we can, all alike at least, help in the good work by repeating and verifying the work done by the pioneers of science, and so contribute even an imperceptible mite to that beneficent knowledge which our profession, to its credit be it said, has ever held to be the common heritage of humanity.

Clinical Lectures. Baris

PYO-PNEUMOTHORAX FROM NECESSITY.

By PROF. GALLIARD.

LOOK attentively at the chest of this patient; the peculiar character it presents is one which you will not perhaps see again. It is the first time I have met with it myself, though I have been on the look out for such a chest for several years. You will observe on the left of the sternum and over the three first intercostal spaces a hemispherical swelling about an inch in diameter at the base, which increases

in size at every effort of the patient.

This tumour is indolent, soft, and compressible to the touch. On applying the ear a kind of splashing sound is heard, derived doubtless from the collision of gas and liquids. The tumour, further, is pulsatile, the beating being synchronous with the pulse. It is also reducible, as can be observed when compressed with the hand, giving the sensation of hernia of the lung. Consequently at this point there exists a cavity, for the time being circumscribed, which communicates with the thoracic cavity by a narrow orifice and contains a mixture of liquid and gas. This liquid is necessarily purulent. You can gas. This liquid is necessarily purulent. You can easily ascertain after reducing the size of the tumour that the narrow orifice is seated in the second intercostal space near the sternum. Change the position of the patient. Instead of examining her in the dorsal decubitus, place her in the sitting position, and you will remark that the tumour is more resisting, and gives the sensation of simple crepitation. Put her on her face and hands—the crepitation disappears, fluctuation alone is felt. The explanation of the phenomena is easy. In the first case the liquid gravitated out of the tumour, the gases alone occupying the tumour, while the reverse obtained in the second position. Thus examined, the diagnosis becomes easy. I will not lose time in discussing the hypothesis of a

What was the origin of this cold abscess? Was the point of departure a tuberculous vomica of the lung? An unwary observer would naturally answer in the affirmative, for he would be influenced by the recent publications of Barie, Louligoux, and R. Meslay. But I hasten to state that the signs of pulmonary excavation behind the gaseous abscess are wanting in this case. The hypothesis of a gangrenous cavity should not be entertained either, as there is no feetid expectoration. We are thus, by way of elimination, brought to locate in the pleura itself the origin of the abscess; it is a case of pyo-pneumothorax from necessity.

The case is a rare one, I admit, and I would not have brought myself to form this diagnosis if the arguments had not been furnished by the signs you have witnessed yourselves and by the clinical evolution of which I shall now give you the essential

details

The case is that of a woman, set. 45, who, while walking on the footpath at the beginning of last December, was knocked down by a milk cart and severely hurt by the feet of the horse and by the wheel of the vehicle. She was picked up more dead than alive, and brought direct to the hospital St. Antoine, where my colleague found several wounds on the head, a fracture of the left clavicle, several fractures of the ribs and subcutaneous emphysema of the thoracic wall, indicating laceration of the pulmonary tissue. The prognosis was bad. However, under appropriate treatment, the frail organism surmounted more or less these troubles, respiration became easier, the traumatic emphysema subsided to a certain extent, and matters were improving. But a few days afterwards, the temperature went up, the respiratory troubles became aggravated, and the following day my colleague showed me the patient, declaring that the pleuro-pulmonary complications belonged to the domain of medicine. According to him the subcutaneous emphysema was accompanied by a partial pneumothorax on the left side. The coincidence of subcutaneous emphysema and pneumothorax is not an everyday occurrence, because the conditions which favour the passage of air into the cellular tissue of the wall are, as you know, those which are opposed to penetration in the pleural cavity. For subcutaneous emphysema, it is necessary that the lung should be fixed to the wall by the fractured ribs, whereas, for pneumothorax, an open wound of the pulmonary parenchyma, a lung free from adhesions, moreover, a retracted lung, are necessary. However, the coincidence is possible, especially when several ribs have been fractured. A minute examination of the patient permitted me to affirm one thing, namely, that the pneumothorax if it existed was not situated at the Under the clavicle, on the other base of the lung. hand, I found that the vesicular murmur was abolished, so that I was inclined to admit the existence of a partial pneumothorax as suggested by my colleague. In any case the patient was handed over to my care and a few days afterwards traumatic pleuro-pneumonia manifested itself, and on December 29th I tapped the side, withdrawing only twelve ounces of sero-sanguineous liquid; the pleurisy was evidently encysted. The following days the temperature oscillated, while the dyspnœa was considerable and the general condition bad, without doubt. The liquid was increasing in quantity and rapidly becoming purulent. Examination of the base of the lung revealed nothing beyond the presence of empyema, no metallic sound nor signs of Hippocratic succussion, yet the heart was displaced towards the right side and showed signs of dry pericarditis. Why this dis-placement with such a small amount of liquid in the left base? It was because the empyema did not constitute the only lesion; there was a pneu-

mothorax beneath the clavicle, which was demonstrated by increased resonance of that region, by a complete absence of the vesicular murmur, by an amphoric souffle perceived in the third intercostal space, and by the presence of an intermittent metallic tinkling. Was I not right to insist on the encysted nature of the pleurisy? Thus only can be explained the singular phenomenon of the cohabitation of pneumothorax and empyema under the same roof, in the same house, in two distinct stories of the left pleura. It was not necessary to be a great prophet to foresee that by reason of the close contact of the empyema, the pneumothorax would not be slow to transform itself into pyo-pneumothorax. I was waiting for the succussion sound, but probably the cavity was too small and the liquid not abundant enough to produce it. But in its place here is the gaseous abscess which fully demonstrates the suppurative process.

The prognosis being very grave we must not wait for the spontaneous rupture of the abscess; to-morrow morning we will incise freely the second intercostal space and treat the empyema in the usual manner.

The Coulstonian Tectures

ON THE

PATHOLOGY OF THE THYROID GLAND.

Abstract of Lecture II, delivered before the Royal College of Physicians of London.

By GEORGE R. MURRAY, M.A., M.D.Camb., F.R.C.P., Heath Professor of Comparative Pathology in the University of Durham; Physician to the Royal Infirmary, Newcastleupon-Tyne.

REFERENCE to the result of loss of thyroid secretion in the young, the lecturer quoted evidence to show that in young animals and children, in addition to other symptoms, there was arrest of development. If the arrest of development or destructive disease of the thyroid occurred early in life, symptoms of primary cretinism, which are the same in the sporadic as in the endemic form, soon began to appear.

In myxedema in the adult as in cretinism different degrees of severity were found. As the success of treatment depended so much upon an early start, he urged the importance of carefully considering the possibility of cretinism in all cases where some arrest of development was noticed early in life. The older the child at the time of the onset the less marked the want of development, and the more nearly

the disease resembles the adult type.

When the supply of the secretion was renewed, metabolism was once more completed in a normal manner, and in cretins was so markedly reawakened that general growth again progressed even after it had been arrested for ten or twenty years. Schiff and Von Eiselsberg had shown that a portion of thyroid gland successfully transplanted into the subcutaneous tissues of a dog or cat could maintain a sufficient supply of secretion to avert the acute symptoms of athyroidism, and Mr. Victor Horsley made a great step in advance when he suggested that a similar procedure should be adopted in man. The procedure had been followed in certain cases by marked improvement, but unfortunately the grafted gland appeared not to be able to maintain an independent existence for long, and the symptoms returned. The excellence of the temporary results obtained, however, had led Dr. Murray to suggest that a simpler method of maintaining the necessary supply of thyroid secretion would be the continued internal administration of the secretion itself. With

this view he had prepared a glycerine extract, and such an extract was now official in the British Pharmacopæia. At first he had administered the extract by hypodermic injection, but it was shown independently by Howitz, E. L. Fox, and Mackenzie that it was quite efficient when given by the mouth. The administration of thyroid extracts in animals deprived of their thyroid glands rendered it possible to distinguish between the symptoms due to loss of the thyroid. It seemed probable that the acute nervous symptoms in the monkey, such as the fibrillary twitchings, the spastic rigidity, and perhaps also the tremors and convulsions were largely due to loss of the parathyroid, while the subcutaneous swelling, dryness of skin, loss of hair, subnormal temperature, and changes in the blood were due to loss of the thyroid secretion. That conclusion received further support from the close resemblance of the latter symptoms to those of primary myxœdema in man, which they knew to be the result of disease of the thyroid gland, there being no evidence as yet to show that the parathyroids were affected in this disease. If that be the correct explanation, it was not surprising that these particular symptoms were not influenced by the thyroid extract.

In primary and secondary myxedema in man were seen the results of loss of thyroid secretion pure and simple, and consequently they were able to remove the symptoms entirely by giving a suffi-cient supply of the secretion. The treatment was divided into two stages. During the first stage the tissues were gradually brought back to a normal condition. That might, according to the severity of the symptoms, require from one to three months. As soon as the symptoms had entirely disappeared, the first stage was completed. The condition of the atrophied thyroid gland was not influenced by the treatment, so that if the artificial supply of secretion were discontinued all the symptoms of myxædema would gradually return, as he had found by actual experience. The second stage of the treatment of necessity thus lasts as long as the patient lives. It is therefore necessary to make the permanent daily dose as nearly as possible equivalent to the normal amount of secretion. If the dose fell below that slight symptoms of myxcedema would reappear, while if excessive a condition of thyroidism would be produced.

In out-of-the-way places, and where expense was a consideration, the actual gland itself containing the secretion might be administered. One-eighth to one quarter of a lobe of the sheep's gland was a suitable daily dose, one quarter being equivalent to about 10 minims of liquor thyroidei. It should be minced and taken in glycerine or some similar vehicle, or lightly cooked on the outside by frying or boiling. As a rule, however, it was better to employ one of the preparations of the thyroid gland. The liquor thyroidei was the most convenient preparation for general use, and in his experience the most efficient and uniform in strength. Not more than a sufficient supply for a fortnight should be obtained at one time, and the patient should measure out the dose and mix with a dessertspoonful of water at the time of taking. The dry thyroid of the Pharmacopæia might be given as a powder, or made up into a pill or tablet. Dampness rendered the dried preparation liable to decompose and unfit for use.

In advanced cases the first stage of the treatment must be carried out with great caution, especially in presence of symptoms of degeneration of the cardiac Under these circumstances the patient should be confined to bed at first, and only small doses of three to five minims of liquor thyroidei given each night. This dose, if well borne, might be gradu-

returning vigour too soon, before the heart has time to recover, and to adapt itself to the altered conditions brought about by the treatment. Now, however, most of these patients were seen in the early stages before any cardiac symptoms developed. Such patients were able to go about, but unusual exertion should be avoided during the first stage of the treatment. Undue acceleration of the pulse to 90 or 100, or rapid loss of weight were indications for reducing the dose.

THE MEDICAL PRESS.

Symptoms of gastro-intestinal catarrh were sometimes seen when a raw gland was used, but seldom after a suitable preparation. When they arose the treatment should be stopped until they had passed away, and when the treatment was recommended smaller doses should be given. When there was well-marked anæmia it was as well to give iron as well as thyroid extract, and for this purpose five grains of dried sulphate of iron in a pill two or three times daily would answer the purpose.

The second stage of treatment began after all the symptoms of myxodema had disappeared. During this stage, which lasted whilst the patient lived, he must continue to take a daily dose equivalent to the daily output of the gland before it became diseased. An occasional intermission of a week or so had little or no effect, but if it lasted three or four weeks the temperature fell one or two degrees, and the myxedematous swelling of the face began again to

develop.

When the treatment of a well-marked case of myxœdema was carried out on the lines just indicated, very definite and interesting results were soon obtained. One of the earliest signs of improvement was the return of the temperature to the normal level. This was illustrated by the chart shown, by which it would be seen that the temperature before treatment ranged from 95 degs. to 96 degs. F., whereas during the second, third, and fourth weeks of treatment it varied between 96 degs. and 98 degs. As the temperature rises to normal the former sensitiveness to cold was lost, and the frequency of the pulse was increased. The most striking changes were those which took place in the skin with its appendages and in the subcutaneous tissues. The myxœdematous sweiling gradually disappeared from all parts of the body, so that the face and hands once more assumed their natural appearance, and the free movement of the limbs, which had been considerably hampered by the swelling, was regained. The reduction of the swelling was accompanied by a loss of weight, which might amount to as much as two or even four stones. Not infrequently there was some desquamation which might occur in fine scales or in large flakes from the palms of the hands and soles of the feet, as observed by Byrom Bramwell. The bair follicles resumed their proper function, so that even where there had been complete baldness a good growth of hair was developed in the course of six or twelve months.

In addition to these very obvious signs of improvement, the feeling of lassitude passed away and normal muscular strength and activity were regained. Mental processes became more active, the memory improved, and hallucinations disappeared. In some cases in which actual insanity had occurred it also had been cured. If albuminuria without actual renal disease had been present it disappeared, while the amount of urine was increased. The observations of Ord and White showed that the total amount of nitrogen eliminated was increased, and that the increase was almost entirely due to the increase of urea in the urine. At first the amount of urea excreted might not only equal but actually exceed the normal average quantity. The number of red corpuscles in the blood was increased. In patients who had not ally increased up to ten minims. If not confined to reached the menopause menstruation returned, and bed these patients are apt to make use of their took place regularly, even where there had been amenorrhea for several years. In fact, the myxœdema was entirely cured, though the fibrosis of the thyroid gland remained unaffected.

THE MEDICAL PRESS.

TREATMENT OF CRETINISM.

The lecturer insisted on the importance of carefully considering the possibility of the presence of disease or lack of development of the thyroid gland in every case of arrest or delay of development in children. In all such cases it was important to look for slight signs of cretinism. The importance of early diagnosis in such cases lay in the fact that the earlier the treatment was commenced the better prospect there was of normal development of the central nervous system. Experience had already shown that in cretinism of some years' duration rapid as the improvement in the physical condition may be, the intellectual development was much slower, so that when treatment was commenced late it was doubtful if the latter would ever advance nearly as far as when treatment was started early. If any doubt existed as to the diagnosis, it was a good plan to carry out the treatment for one or even two months. If no distinct improvement took place the want of development was not due to cretinism, for in otherforms of arrested growth the treatment had comparatively little effect, though it is worthy of trial. The treatment of early cretinism should be carried out on the same lines as the treatment of myxædema in the

In the treatment of cretinism which had lasted for some years they had a much more difficult task to perform, but very good results could be obtained. Even where the disease had already lasted ten or twelve years, provided the patient was not more than eighteen or twenty years old, a remarkable amount of growth could still take place. In those cases three to five minims of thyroid extract might be given at the commencement, and increased according to the progress observed. Even in cases in which the symptoms had lasted for twenty or twenty-five years some growth and marked improvement in all the symptoms took place, In cases of long duration attacks of syncope were not uncommon. In such the earlier part of the treatment was more safely accomplished by keeping the patient in bed, and giving small doses of one or two minims only at first.

When the necessary stimulus to the normal metabolism of growth was thus supplied to a cretin in the early stages of the disease the symptoms soon disappeared. The swelling gradually diminished in all parts of the body; the tongue, lips, and nose diminished in size, so that the appearance became natural; the skin became soft and moist and the temperature rose to normal. Growth, which at this early stage would only have been partially arrested, started afresh. If the treatment was continuously carried on in such a case from the earliest time at which the disease was recognisable, there seemed no reason to doubt that ultimately the child would grow up into a fully developed, healthy adult, who, however, would, of course, at any time develop symptoms of myxedema if his supply of the extract was discontinued.

The intellectual development was always much slower than the bodily growth and general improvement in all other respects. The shorter the duration of symptoms had been at the commencement of the treatment the more rapid the improvement in the mental condition, and Dr. Murray thought it was only in cases in which the treatment was started early that they could expect normal intellectual development to take place. In cases of some duration it was important that a special education should be carried on at the same time as the treatment in order that the patient might be able to make the most of his renewed cerebral activity.

CASES OF

ABDOMINAL HYSTERECTOMY FOR FIBRO-MYOMATA UTERI. (α)

By CHARLES RYALL, F.R.C.S.,

Surgeon to the Cancer Hospital, Brompton; Surgeon to Out-Patients, London Lock Hospital.

CASE I.—M. B., æt. 54, consulted me on September 27th, 1898, and gave the following history:—

For thirteen years she had noticed a tumour in the abdomen, but it has only troubled her during the past two years, during which time it has been gradually enlarging, but more rapidly so during the last few months. There has been much pain in the abdomen and lumbar and sacral regions, which is aggravated by walking too much, so that the patient is unable to get about and attend to her household duties. There has been a great loss of flesh. The bowels are constantly constipated, and micturition is both frequent and painful. Catamenia began at age of 13. Regular, no excessive loss. Always severe dysmenorrhea. Menopause at age of 45. Children two; youngest 32 years old. No miscarriages.

On examination a hard nodular and irregular mass about the size of a cocca-nut can be felt in the hypogastrium. Dull on percussion and extremely mobile.

trium. Dull on percussion and extremely mobile.

Per Vaginam.—The cervix is pushed over to the right side, and a freely movable nodular mass can be felt in the left and posterior fornices, and is feund to be part of the abdominal tumour, and is incorporated with the uterus.

abdominal tumour, and is incorporated with the uterus.

Operation, October 5th, 1898.—Abdominal hysterectomy by the subperioneal method was performed, which also included removal of the left ovary, and the abdominal wound was sutured in three layers. The patient went on very well on the first and second day following operation, and a little fæces and some flatus were passed after administering 3 grains of calomel and an enema. A little flatus was also passed on the morning of the third day, but about noon on the same day the patient was seized with sudden acute pain in the left iliac fossa, followed by a little sickness. On examination there was a great deal of tenderness limited to the left iliac fossa, and the colon was greatly distended, and in a few hours the distension spread to the small intestines. Repeated 5 grain doses of calomel were given, and every attempt was made to open the bowels by enemata and the long rectal tube, but neither fæces nor flatus was passed. The abdomen was reopened six hours after the onset of the symptoms, and it was then found that the sigmoid loop was kinked and bound by recent adhesions to the remains of the left broad ligament. The bowel was easily freed, but on pulling it up it was noticed that there was a good deal of tension on the ligature embracing the upper part of the left broad liga-ment, and owing to the proximity of this ligature to the meso-sigmoid, it was thought that it might possibly cause a continuance of the symptoms. As the patient was in a very feeble condition, and as there was a great deal of liquid faces in the colon, the sigmoid was sutured to the abdominal wound and drained by means of a Paul's tube. The tube was removed on the fifth day, after which the bowels acted naturally, and the fistula gradually contracted and eventually closed in a month's

There is no doubt that the kinking and adhesion caused the obstruction, but a ligature close to the mesosigmoid, and thus interfering with the blood supply or nervous innervation of the part, may cause similar symptoms.

CASE II.—Abdominal Hysterectomy for Fibro-Myoma Uteri, followed by Rupture of the Abdominal Wound.

F. H., æt. 32. unmarried, consulted me on November 28th, 1898. Menstruation began at the age of 13, and ever since then she has suffered great pain at the periods. The pain now commences after the first day of the flow, and is usually at its worst on the third and fourth day, and is so severe in character that it frequently makes her cry out. Moreover, she is quite incapacitated from work at

⁽a) Notes of cases read before the British Gynæcological Society (March 23rd, 1899) and specimens shown. See "Transactions of Societies," April 5th, page 350.

the time. The duration of the period is five to six days, during which there is a great loss, with occasional pass-ing of clots. For the last six months the symptoms have become worse, and she has also suffered from severe sacral pain in the inter-menstrual period. Medicinal treatment and rest have given her very little relief.

Family History.—Her sister has also consulted me, and is suffering from fibro-myomata uteri, causing similar

On examination, a hard, smooth, solid tumour can be felt in the abdomen, and rising for about two inches above the pubis. Per vaginam, this tumour was found to completely fill the pelvis, where it was fixed, and was

bulging down the vaginal fornices.

Operation, December 9th, 1898.--Abdominal hysterectomy by the sub-peritoneal method was performed, both ovaries being left behind. The operation was both difficult and tedious, owing to being unable to lift the tumour out of the pelvis or to get the hand below the tumour so as to reach the cervix and secure the uterine vessels. After securing the upper part of the broad ligament on each side, the peritoneum was incised over the tumour and peeled off, and then enucleation of the tumour was performed, after which it was lifted out of the pelvis, the uterine vessels secured, and the mass severed. The peritoneum was sewn over the stump with catgut. The parietal peritoneum was closed with a continuous catgut suture, the musculo-aponeurotic layer with interrupted silk sutures, every care being taken to bring the fascia into careful apposition, and finally the skin was brought together with a continuous silk suture.

The patient bore the operation well and made good progress after operation until the fifth day. The bowels had acted several times, but there was occasional

retching.

On the afternoon of the fifth day I was called suddenly to see the patient, and found her practically moribund. She was unconscious, the face was a dusky grey colour, the breathing was rapid and shallow, and the pulse 137 and almost imperceptible. The onset of these symptoms was sudden, but I was at a loss to understand the cause of this collapse. Hypodermic injections of ether and strychnia were given immediately, followed by intravenous injection of five pints of normal saline solution. The effect was immediate and most satisfactory, for the patient suddenly woke to consciousness, and the pulse and respirations improved. She then told me that she had some retching, when she was seized with pain in the epigastrium, after which she could remember no more. This made me think that possibly there might have been some intra-peritoneal extravasation, and that the shock caused the sudden collapse, but on examining the abdomen the edges of the wound seemed in apposition, there was slight tenderness, but I could find no reason to re-open the abdomen. Three hours after this she collapsed again, and intravenous injection of saline fluid had only a very temporary effect. The abdomen was again examined, and it was then found that the edges of the skin in one portion of the wound were gaping, through which came a quantity of serous fluid on pressing the abdomen. I therefore removed the cutaneous suture and found that the two deeper layers of sutures had completely given way, the sutures having torn through the tissues. The wound was now reclosed with sutures, including the whole thickness of the abdominal wound, but the patient gradually sank and died in a few hours. The necropsy revealed nothing of note, except that there appeared to have been no attempt at union in the abdominal wound.

The case is of interest showing as it does that, even after taking every precaution, accidents may happen. The sudden cause of the collapse was at first a mystery to me, but now one knows that it was due to the shock of the rupture of the deeper layers of the wound, and thus simulated the perforation of a gastric ulcer. superficial suture for a time kept the skin in apposition, and thus prevented me from immediately detecting the nature of the accident.

CASE III .- Case of Abdominal Hysterectomy for Myoma Uteri causing severe Hæmorrhage.

M. S., æt. 35, married, no children, has suffered from

menorrhagia during the last four years, and the loss is so severe that the patient became almost completely blanched, and frequently faints. There is also a slight irregular loss between the periods; slight dysmenorrhœa. Catamenia began at age of 13, and were regular up to four years ago.

On admission the patient was thin and feeble, and

suffering from severe anæmia.

On examination a soft smooth swelling could be felt in the hypogastrium, and reaching to within two inches of the umbilicus. Per vaginam the os was patulous, and a soft round swelling could be felt within, and impli-cating the right side of the uterus could be felt a tumour which was continuous with that felt in the abdomen. The whole mass was quite movable.

Operation in the Cancer Hospital, Jan. 25th, 1899.-The uterus was first explored per vaginam, and a myoma about the size of a cocoa-nut could be found bulging into the uterine cavity, and standing out prominently on

the peritoneal surface of the uterus.

Abdominal hysterectomy by the intra-peritoneal method was then performed, and it presented no difficulties. The patient bore the operation well, and made a rapid recovery.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON. MEETING HELD WEDNESDAY, APRIL 5TH, 1899.

Mr. Alban Doran, President in the Chair.

MENSTRUATION IN A MONKEY.

DE. Addingell showed a section through the uterus. cervix and vagina of a monkey calling attention to the enormous size of the cervix. It was removed from a "Bonnet" monkey, and it formed one of a series of abdominal hysterectomies performed on monkeys during menstruation, the object being to decide the question of the shedding and denudation of epithelium during menstruation. He pointed out that in monkeys the menstrual discharge did not usually contain blood, but was glairy mucus. He mentioned that in Barnum's Show there was a monkey, a chimpanzee, 14 years of age, which had begun to menstruate at 12. Since that time menstruction had taken place with great regularity every 28 or 30 days. He said this was the first instance of a well authenticated case of an animal high up in the scale, other than woman, in which menstruation had been observed to take place with regularity.

ANTERO-POSTERIOR POSITIONS OF THE HEAD AS A CAUSE OF DIFFICULT LABOUR.

Dr. R. G. McKerron read a paper on difficult labour as the result of the antero-posterior position of the head. probably the most uncommon of malpresentations. He related two cases to illustrate his contention. Case 1 .-Mrs. B., æt. 41, the mother of ten full-term children, all save two delivered by the aid of forceps. Labour set in on the evening of November 30th, and when seen at midnight on December 1st, the os was fairly dilated, but the head was above the brim, with the occiput anteriorly. The posterior fontanelle could be felt 11 inch from the symphysis, the sagittal suture running almost directly backwards. Traction with forceps proved fruitless, and the blades tended to slip. On further examination the anterior fontanelle could be felt just above the promontory to the right of the middle. He cautiously rotated the occiput backwards so as to bring the long diameter of the head into the oblique of the pelvis whereupon labour was promptly terminated with moderate traction. The mother made a good recovery, but the child, which was well formed, died three days later. Measurements of the pelvis gave as follows:—interspinous 8.75 inches; intercristal 10.25 inches; external conjugate 7.1 inches. Case 2.—J. C., æt. 38, one child delivered with forceps, was admitted at 10 p.m. on December 15th, labour having just started. The cervix was drawn up, and the os admitted one finger. The pains were strong until

3 a.m., when they suddenly ceased but returned the following afternoon. On external examination the child was found dorso-anterior with the head free above the brim. The posterior fontanelle could be felt in front of the centre of the os an inch or more from the symphysis, and the sagittal suture was found to run backwards in the conjugate of the brim. The diagonal conjugate was made out to be barely 41 inches. Guided by the previous case he forthwith proceeded to rotate the head backwards and labour was promptly terminated by the aid of the forceps. The child weighed 8½ pounds, there was no great caput succedaneum and no marked elongation of the occipito-mental diameter. The child died on the third day, and post-mortem the subdural space was found filled with blood and the ventricles contained sero-sanguineous fluid. After labour the hand was passed up to the pelvic brim which was found to be rounded in outline, and the conjugate was estimated at just over 31 inches. The external measurements were: interspinous 9 inches, intercristal 10.6 inches, external conjugate 7.5 inches. He observed that these positions were often overlooked, probably because without anæsthesia their recognition was difficult owing to the high position of the head. The diagnosis rests on the antero-posterior position of the sagittal suture. In such cases the head, prematurely arrested, fails to accommodate itself to the brim and to the lower segment so that dilatation is slow. If diagnosed before rupture of the membranes an attempt should be made to correct the condition by external manipulation; after rupture the head should be inclined laterally as advised by Ramsbotham. Manual alteration of the head above the brim is useless unless the body can at the same time be rotated by abdominal manipulation, otherwise the head reverts to its old posi-tion. When the os is sufficiently dilated the forceps should at once be applied, and the position rectified in the manner described above. In these two cases craniotomy would have been the only alternative, but earlier recourse to the forceps to effect rotation would pro-bably have saved the lives of the children.

A CASE OF PUERPERAL ECLAMPSIA WITH A DESCRIPTION OF A FIVE WEEKS' OVUM REMOVED IN A SUBSEQUENT PREGNANCY.

Dr. W. S. A. GRIFFITH related the case of a married lady, et. 32, who suffered from eclampsia at about the seventh or eighth month of her third pregnancy. Labour was induced by Dr. Griffith, with the intra-uterine bougie, and she recovered. About eighteen months afterwards she again became pregnant, and severe symptoms ensued as early as the fifth week. Dr. Archibald Garrod reported that there was evidence in the urine of chronic nephritis, and the uterus was therefore dilated by the rapid method, and the ovum removed. The symptoms thereupon rapidly disappeared, but a trace of albumen persisted in the urine for some time. The ovum removed was in naked-eye appearances healthy. It measured 3 by 2.75 cm., and the fectus measured 11 mm. in length. The cephalic end could be made out, but the limbs were barely perceptible. The outer wall of the ovum was thickly beset with villi over seven-eighths of its total area, the remaining eighth consisting of a white membrane of very delicate consistence. The detachment of the villi from the maternal structures was complete in every part, no trace being seen of serotina or reflexa. Hardened and examined under the microscope the superficial plasmodial layer of the chorionic epithelium showed marked and widespread changes, clearly of pathological origin. In parts the layer was practically destroyed by vacuolation, the larger vacuoles having been formed by the fusion of adjacent smaller vacuoles, it being easy to follow the process of coalescence. The number of nuclei was below the normal, and their distribution was irregular, they being gathered together in clusters in the least affected parts. The same changes were seen not only in the villi, but also in the plasmodial buds and processes. Where vacuolation was marked the deep or cellular layer of the chorionic epithelium had disappeared. The blood vessels in the chorionic stroma were normal in number and distribution, and were packed with blood corpuscles. The fortal blood had undergone slight changes, the corpuscles

having lost their sharp outline, and many being in a state of disintegration. Almost all the cells were nucleated. The connective tissue stroma supporting the vessels and the deep or cellular layer of the epithe-lium were much altered in all parts. The meshes were greatly widened, the reticulum in many villi broken up and irregular, and the nuclei greatly reduced in number, and even absent altogether. Such as remained were shrivelled and distorted but not vacuolated. The cells of the deep epithelial layer had disappeared pari passu with these changes in the stroma. Specimens hardened in osmic acid showed a large deposit of fat in the protoplasm of the plasmodic layer, most marked in the villi which showed least vacuolation. Whether this excess of fat is pathological is open to question. In the intervillous spaces there was a good deal of fresh unaltered blood (maternal) and a small deposit of fibrin upon some of the villi. In the serotina the decidual cells were comparatively healthy, but in the sera and reflexa they show marked changes. They had no cell envelope, and the cell bodies were practically destroyed. Extensive fatty degeneration was present in all the altered decidual cells. In this case it is certain that the ovum was in situ up to the moment of its removal, though it cannot be affirmed that the feetus was living at the time of interference. It seems probable that the changes described in the feetal and maternal structures occurred during the life of the feetus, and in all probability rapidly led to its death. With regard to the etiology, it is possible that the ovum was grafted upon an unhealthy endometrium, and the chronic nephritis from which the mother suffered may possibly be the ultimate pathological factor, but this conclusion cannot safely be deduced from a single case.

The PRESIDENT raised the question as to the relative pathological responsibility of the mother and the fœtus respectively. He himself inclined to the view that eclampsia was always the fault of the mother, but he recalled the theory that eclampsia was a toxemia set up by the fœtus which subsides when the offending fœtus was removed.

Dr. A. ROUTH asked the author why he had not adopted a more expeditious method of determining pregnancy, suggesting that it would have been better to have ruptured the membranes. He asked whether the albumen in the mother's urine comprised globulin. He thought the appearances were in favour of a feetal or placental biological change.

Dr. Griffith, in reply, said the case was of interest as belonging to a small group of cases of albuminuria with chronic kidney disease. It was a case in which the changes in the decidua were so marked that they formed a fresh point de départ for degenerative changes, but what relation they bore to the whole subject he was unable to state.

ROYAL ACADEMY OF MEDICINE IN IRELAND
SECTION OF SURGERY.

MEETING HELD FRIDAY, MARCH 3RD, 1899.

The President, Mr. R. L. Swan, in the Chair.

DISEASES OF THE FOOT.

Mr. W. I. De Courcy Wheeler related five cases of complete excision of the os calcis, followed by the most satisfactory results; one case of excision of the os calcis and astragalus, with portions of the tibia and fibula; thirteen cases of medio-tarsal operation, or Chopart's operation, all showing as favourable results as the patient (exhibited at the Society) on whom he performed this operation twenty years ago; also three cases of complete excision of the astragalus for disease, besides others for compound dislocation. There was a brief record of thirty-nine cases after Symes' operation, also results after Tripier's operation, which he was of opinion had as many advantages over the subastragaloid operation as Chopart's had, but had not the advantages claimed over the medio-tarsal operation, except with those who believe that in Chopart's operation the astragalus is thrown

forwards against the scar, which is quite preventible in a properly executed medio-tarsal operation, and does not occur when the plantar flap is made sufficiently long. After a record of the excisions of various bones of the foot, and six resections of the first metatarso-phalangeal articulation, the paper concluded by a description of metatarsalgia Madura foot and two cases of podal coma, so graphically described by Professor Miller. One case completely recovered, the second had a recurrence of the disease. There was no history of any constitutional or predisposing cause why the patient's foot—a male about thirty-two years of age—should be attacked by this painful disease, except in Miller's words, his "system was weak and miserable." His parents were both alive, and remarkably healthy.

Mr. CroLy said that he was not in favour of excision of the os calcis, because in a patient with tuberculous os calcis the disease was rarely confined to that spot. If touched at all, he approved of its entire removal, the bone being removed in such a way that the incision should not be under the heel, but rather behind it. Excision of the os calcis was a good operation in case of accident. He considered Chopart's operation very good, because if the disease was confined to all the bones in front of the medio-tarsal line, a sound astragalus and os calcis were left. Podal coma required amputation of the foot. Nelaton's perforating ulcer of the foot was a rare uffection, and was connected with certain forms of neuritis, and sometimes in connection with diabetic condition of urine.

Mr. T. Myles related a very remarkable case of tuberculosis of the foot after injury. A small abscess formed, which was opened, and probing showed some bare bone apparently over the cuboid. The bone was dissected out, and the girl apparently got well. Bits of bone had, nevertheless, to be scraped away from time to time. Two months ago a consultation was held, when it was decided to amputate the foot, but from that moment, to his astonishment, the young lady recovered rapidly, and is now perfectly well and going about.

The President considered that any tuberculous disease of the metatarsal bone at least should not be submitted to any operation except upon the bone itself, and many cases of tuberculous disease were confined to the metatarsal bones. The literature of the subject seemed to show that tuberculous disease of the os calcis is in reality the tuberculous disease of the foot which can be most frequently attacked with success. He related a case of tuberculous disease of the ankle-joint which, after a time, got practically well. Subsequently the patient developed tuberculous disease of the elbow, and a little later a tuberculous abscess in the iliac fossa.

Dr. Henry Fitzgibbon said that in cases of disease of the bones of the foot he approved of minor surgical methods before resorting to amputation. He related a case of a young girl whose middle cuneiform bone he removed for tuberculous disease. Recovery took place.

Mr. Chance said the case related by Mr. Myles was very exceptional. He thought that too much attention was given to the mapping out of the bones, as tuberculous disease travels pretty much by the tendons and other structures. While he agreed that certain bones which are affected in small part of their bulk should be entirely removed, he thought that excision of such bones rarely gave room for free removal of the soft structures.

Sir F. CRUISE had seen the partial operations done successfully fifty years ago, so that the subject was not at all new. He observed that in a fairly healthy patient complete removal gave a good result, but that if the patient's constitution was decidedly taberculous, even amputation did not save him.

Mr. WHEELER, in reply, said that excision of the os calcis was favourable, because the synovial sac is limited, thus preventing rapid extension. The sooner the bone is removed the better, and he did not approve of the gouge in removal, because it was difficult to say whether one was in healthy or unhealthy tissue, and still more, in strumous patients the use of the gouge might set up inflammatory action which would produce more carious disease. The podal coma he had seen was the same as hat described by Miller.

PERFORATING GASTRIC ULCER.

Mr. T. Myles related a number of cases of perforating gastric u cers on which he had operated, which we publish in extenso in another column.

Among the cases narrated was that of a gentleman, æt. 72, who, after the reduction of an umbilical hernia, developed symptoms of perforation. When he was called in the patient was sinking rapidly, with great pain and tenderness, persistent vomiting of black tarry matter, evidently altered blood, complete absence of liver dulness, tympany, &c. Operation seemed hopeless, but was undertaken in consequence of the agony the patient was suffering. The perforation was easily found, sutured, and abdomen freely douched with hot saline Patient made a complete recovery. Mr. Myles contrasted the ease with which an anterior perforation was found and handled, with what happened in posterior perforation.

Sir F. Chuise insisted on the maxim nil desperandum. The patient who had been under his care was almost pulseless at the commencement of the administration of the chloroform; the pulse became much better when the chloroform was changed to ether.

Mr. WHEELER congratulated Mr. Myles on the excellent result, which showed that early operation offers better chances of recovery than delayed operation. He preferred swabbing out the abdomen to douching. He had seen saline solution revive a patient on whom he operated for tuberculous peritonitis. It depended on the position of the perforation of the stomach whether the

operation could be rapidly done or even done at all.

Mr. Chance mentioned the case of a young woman with gastric ulcer who suddenly became collapsed with symptoms of perforation. Laparotomy was at once performed, but thorough examination of the stomach revealed nothing. The abdomen was closed, and recovery followed. In another case, that of a woman, he opened the abdominal cavity, and found in an abscess a small cavity, a good deal of flocculent material, and a considerable quantity of undigested food. He drained the abscess, and recovery followed. The mortality of stomach operations seemed very high according to statistics, because the operation was so often done for malignant disease.

Mr. Myles replied, and the Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

An ordinary meeting of this Society was held on APRIL 7th in the Society's Rooms at the West London Hospital,

The President, Dr. S. D. CLIPPINGDALE, in the Chair.

Dr. S. T. Pruen, of Cheltenham, read a paper on RECENT ADVANCES IN THE TREATMENT OF TUBERCULOSIS.

Dr. Pruen commenced his paper by giving the statistics of tuberculosis. Of every eight deaths one was from tuberculosis; of every ten deaths one was from phthisis. He then discussed the transmissibility from man to the lower animals and vice versa, and gave instances to show that tuberculous infection could pass not only between man and animals but also between man and birds, or even fishes; and showed what a great reduction of the mortality among infants could be brought about by the sterilisation of their food. Turning next to pulmonary tuberculosis in adults, he described his visits to the women's sanatoria in England and on the Continent, and especially described the cure at Nordrach, in the Black Forest, where great attention was paid, not only to the question of a proper supply of air night and day, but to over-feeding, to regulated exercise, to proper rest, and to isolation from the cares and pleasures of the outside world. Pruen then showed a book written in 1840 by an Englishman named Bodington, of Sutton-Coldfield, near Birmingham, who carried out in practice a cure for phthisis very like that at Nordrach. This cure was very successful, and one of the patients, who, when she came under his care was in the third stage of phthisis, he described

as being quite cured three years later, and who, Dr. Pruen added, was still quite well, although it is now sixty-three years since she underwent the cure. This cure, although it was successful, was known by Bodington's medical compeers as the "beefsteak and porter cure," and so much ridicule was thrown upon it that the profession, as a whole, were afraid to take it up, with the result that Germany had now the credit of discovering it, although an Englishman was really first in the field.

The paper was discussed by Dr. Gardner (Bournemouth), Dr. F. R. Walters, and the President.

BRADFORD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD MARCH 21st.

President, Dr. BERRY, in the Chair.

Dr. Crowley gave a demonstration of microscopical specimens.

Mr. Hall showed a number of photographs and casts of surgical cases, and gave brief descriptions in each case.

Dr. Lodge read notes on a case of "High Myopia," in which a satisfactory result had been obtained by removal of the lens. The patient was shown.

Mr. Horrocks read notes on a case of

SIMPLE STRICTURE OF THE RECTUM,

which had been satisfactorily treated by a simple operative measure. He remarked that the kind of stricture he had in mind was one within easy reach of the anus and varied in depth from a simple narrow band running round the gut, to an annular stricture an inch in depth. After discussing various theories as to the origin of this affection, Mr. Horrocks remarked that it was more common in women than in men, and that it frequently became very narrow before patients presented them-selves for treatment. Their condition in consequence was one of great discomfort, and in the case brought before the society the patient became insane. Treatment by the passage of bougies is very painful, and does not hold out the prospect of cure. Forcible dilatation is unscientific and dangerous in that the bowel may be torn up to the peritoneal reflection and that cavity become infected. The patient was a woman, et. 55, who had suffered from rectal trouble for twenty years. Had had bougies passed fifteen years before with some temporary relief. Her condition gradually become worse, and her mind was constantly occupied with the rectal trouble. On examination, there was a stricture an inch within the anus which barely admitted the index finger. The stricture was about a quarter of an inch in depth, and the mucous membrane was fixed at the narrowed spot, but above was loose and healthy. No scars were seen on the pudendum or around the anus. On June 10th, 1898, put under E.C. mixture. The anus was thoroughly stretched, and the stricture brought into view. A vertical incision was made one and a half inches long through the posterior part of the stricture; with the fingers the sticture was stretched till this vertical cut became transverse. The mucuous membrane was then held in position, and stitched with chromic gut sutures.

After the operation the narrowed part readily admitted three fingers. The patient did well after the operation, and the bowels were relieved freely and regularly, but she could not be persuaded that the stricture did not still exist. Subsequently she became an inmate of Mearston Asylum.

Mr. Horrocks remarked that the operation was suggested by the procedure of pyloroplasty for malignant stricture, which is exactly similar in principle. He also remarked that it was necessary for the success of the operation that the mucous membrane above the stricture should be healthy, or at any rate that it should be possible to free it from the subjacent tissues. He said that in a second case which he had treated by this method, it had been necessary to thus free the mucous membrane before the vertical incision could be converted into a transverse one.

France.

FROM OUR OWN CORRESPONDENT.

Paris, April 8th, 1899.

EARLY DIAGNOSIS OF CONSUMPTION.

The importance of detecting phthisis in its incipient stage is universally admitted, for at this period the malady is frequently susceptible of being cured, and in the progress of the lesions can be checked in many cases by well-applied hygiene and therapeutics.

Among the recent discoveries facilitating the diagnosis at the earliest stage is that mentioned by Chuguet, who found that the temperature presented a difference of from seven to eight-tenths of a degree between the morning and the evening, or between the horizontal and the vertical position. The tuberculin test was supposed to be conclusive, but it was not exempt from danger, while injections of artificial serum, although giving analogous results, required to be employed with prudence.

The method that would seem to be the most practical was the internal administration of iodide of potassium. Given in daily doses for two or three days of fifteen grains, it provoked in subjects suffering from latent tuberculosis sonorous râles in the suspected regions of the lungs.

Dr. Murat has recently drawn attention to another sign which he considers of particular importance. It consists in an abnormal sensation experienced by the patients. When they speak loudly their voice causes the tuberculous lung to vibrate. When the conversation becomes animated with loud outbursts the same sensation is felt, and he observed one case where the patient sought to attenuate this annoying resonance of the infiltrated region by pressing the arm to the corresponding side. The sign should be sought for with care, as not being painful the attention of the patient is not naturally drawn to it. But if the attendant questions the patient and makes him cough or "ahem" he will recognise that the vibrations of the voice circulate in the left lung, for instance, while no kind of sensation is felt in the healthy side. This sign is produced by a thickening of the parenchyma of the infiltrated lung. Dr. Murat says that the symptom was well marked in one of his tuberculous patients at a time when the most minute auscultation failed to distinguish any morbid

SYMPTOM OF TUMOUR OF THE CEREBELLUM.

Dr. Schmidt, in a recent memoir, reports two cases of tumour of the cerebellum in which the diagnosis, fully confirmed by autopsy, had been established by the presence of vomiting when thepatients lay on a certain side of the body. The first case was that of a woman of 24, who in her childhood presented symptoms of rickets, both her parents being tuberculous. She had already had two children, but when she arrived at the third month of another pregnancy she commenced to suffer from intense headache, localised. particularly in the occipital region. Five months subsequently vomiting set in, which nothing could control. The woman became indifferent to everything passing around her; her memory failed her, and she fell into a state of complete prostration. Artificial delivery was practised, believing that her life was in danger, but this intervention did not produce any permanent result. In

a short time opisthotonos, paresia of the facial nerves on the left side, divergent strabismus with lateral nystagmus set in, and the patient succumbed from œdema of the lungs. Several of the above symptoms might have indicated the serous meningitis described by Quincke, but two signs pointed towards the existence of a tumour in the cerebellum, which were: abolition of the patellar reflex, and the vomiting which was constantly produced as soon as the patient lay on the right side. The postmortem confirmed the diagnosis. The second case was also that of a young woman who had arrived at the fourth month of her first pregnancy. At this point she was seized with vomiting, which continued during the whole period of her pregnancy, and persisted even after delivery. The vomiting was accompanied with violent headache, contractions of the muscles of the neck, vertigo. noises in the ears, and unsteadiness of gait. All the symptoms persisted more or less for fifteen months. Finally she took to her bed and lay constantly on the right side, for as soon as she turned on the left side she was seized with vomiting, vertigo, and noises in the ear. After a few weeks the patient succumbed, and at the autopsy a tumour was found in the right hemisphere of the cerebellum compressing the aqueduct of Sylvius.

Danger of Infection in Tuberculosis.

In the discussion on this subject at the Medical Society, that followed the reading of Dr. Cornet's paper, Hr. Fürbringer gave details as to the prophylactic measures as employed at the City Hospital, Friedrichshain. The measures proposed by Cornet were rigidly carried out. Since the beginning of 1887 placards were hung up in all the phthisis pavilions with the very curt direction-"Spitting glasses are provided for expectoration, and spitting on to the floor or into the pocket-handkerchief is strictly forbidden." These directions were rigidly followed up, and with good results. In the February sitting of the Society of 1890, the speaker had been able to assert that up to then no case of transference of infection had occurred. That proved nothing, and did not weaken the objection that patients might have left the house with latent phthisis. The speaker then went on to report on their experience with their staff of nurses and attendants. In 108 nursing sisters, three had tuberculosis during their term One was previously healthy, of service. had hereditary predisposition, and one was infected before she came. From 1884 to 1890, 708 Victoria sisters were employed, of whom 94 only remained from five to fifteen years. Nearly all had nursed phthisis cases, but not exclusively or always. Since April, 1887, in round numbers 9,000 cases of pulmonary consumption had oeen treated in the various pavilions. The daily average was at least 80, and the length of stay thirty days. Under these conditions thirteen sisters had tuberculosis. One was previously healthy, six were tuberculous before coming to the hospital, and six had hereditary predisposition. Possibly one or more had later on become victims to infection. In these figures lay an enormous contrast to those of earlier periods,

Ziemssen) and even 63 (Cornet) The conditions were similar in the case of the physicians and attendants although they did not come into such close contact with the patients. He did not deny that a number of other favourable factors came into play in connection with the great change. Naturally the sisters did not allow patients to spit in their faces, and when a patient coughed out they turned away, but in the speaker' opinion, the favourable figures were obtained by avoid ing infection "in the dry," without regard to moist infection. From this he drew the conclusion that isolation of phthisical cases was unnecessary. Haupt was right as to hereditary taint, it formed a co-operating cause-Moist infection was, at any rate, rare; transference by the dry route was the regular one, that by the moist exceptional.

THE FREDING OF INFANTS.

Dr. Emil Schlesinger, a kinderarzt in Breslau (*Therap. Menatsch*, 3/99), reports that undiluted cow's milk is the most rational, simple, and economical substitute for human milk, although pseudo-scientists and pseudo-scientific manufacturers of so-called children's foods are doing their level best to relegate it to the past. The subject is an important one, if from an economic view alone, and the doctor would have done well to give us facts on which reliable opinions could be founded.

THE SURGICAL CONGRESS.

The twenty-eighth Congress of the German Surgical Association was opened here yesterday. Besides Professors Gussenbauer, of Vienna; Kocher, of Bern; Kroenlein, of Zurich; and Barker, of London, there were present a large number of German surgeons, including Herren Trendelenburg, of Leipzic; Braman, of Halle; Hoffa, of Wurzburg; and Bergmann, of Berlin, as well as representatives of the Army Medical Staff, and a number of officers of high rank. Speeches were delivered by Professor Koenig, of Berlin, and Messrs. Kocher. Bergmann, and Barker. I shall keep your readers duly informed of the proceedings of this Congress, which is creating a good deal of interest here.

At the meeting of March 1st, Hr. Ratkowsky showed a patient (a medical man) with

RECURRING APPENDICITIS,

the case being peculiar, inasmuch as the viscera were transposed. As a student the patient had an attack of circumscribed peritonitis of the left side, that lasted for six weeks, a year later, he suffered in a similar way in which the medical attendant diagnosed stenosis of the sigmoid flexure as a residuum. The diagnosis was confirmed, inasmuch as the patient during the subsequent years had swelling and vomiting with the slightest constipation. A similar attack occurred recently, and examination now revealed recurring appendicitis, and at the same time transposition of the viscera. This had hitherto escaped previous examiners, as the heart sounds could be heard feebly on the left side, and the examiner had been satisfied with this.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, April 7th, 1899.

PAROXYSMAL HÆMOGLOBINURIA.

lay an enormous contrast to those of earlier periods, AT the "Gesellschaft der Aerzte" Neumann showed a when the percentage of the infected reached 50 (v. patient, et. 28, who was received into hospital four years

ago on account of syphilis which has manifested itself on the mucous membrane and skin several times since that time. About a year ago, for the first time, he passed urine of a dark brown colour after a sharp febrile attack. In December last he came to the hospital as these febrile atttacks began to recur about every three days with the same result in respect of the urine. On February 27th he was admitted into Neumann's ward with a temperature of 40.6 degs. C. or 105.8 degs. F. The urine had the usual dark colour, and contained a large quantity of hæmoglobin, and its derivatives, but no red blood corpuscles. Subsequent observations confirmed the history of a remitting disease usually recurring within from twelve to fourteen hours after a rigor, followed by a rise of temperature; then appeared pain in the joints with an ash-grey colour of the skin. About three or four hours after these symptoms the patient expressed himself as feeling quite well, and the urine resumed its normal character.

The correct diagnosis of the proximate cause gave rise to a diversity of opinion, as paroxysmal hæmo-globinuria may be produced by so many different agents. As a wide variation of temperature between heat and cold, drugs such as chlorate of potassium, diseases such as malaria, chronic syphilis, &c. Ehrlich, Schumacher, and others have demonstrated that anti-syphilitic treatment is a common cause of paroxysmal hæmo-globinuria, and this may have been the cause in the foregoing example.

TREATMENT OF LUPUS.

Lang showed a patient to the Society on whom he had first operated for lupus, and had subsequently performed a plastic operation to remedy the results of the first operation.

The patient, æt. 34, had been operated on some time previously, when the cartilages and alæ of the nose were entirely removed. To supply these defects large flaps had to be taken from the volar part of the right hand, while the volar part was in turn supplied from the side of the thorax. He related the history of seven other cases, in which he had similarly operated with equally good results, but he could not vouch for their subsequent history. Two had recently disappeared; two others had a recurrence of the disease, and two still appeared quite healthy, though now operated on 31 years and 20 months respectively. Lang has tried every form of treatment for this intractable disease, and concludes his disappointing efforts with the consolation that operative surgery and cosmetic repair is the most rational and successful method he has yet tried.

JACKSONIAN EPILEPSY.

Wernlechner exhibited a young man, æt. 28, on whom he had operated twenty-one days previously for epileptic fits.

About three years ago he received a blow from the shaft of a cart on the left temple which rendered him unconscious for some time. After recovery it was found that the left leg and arm were paralysed. A few months after the accident epileptic fits commenced, and have since continued up till the middle of February, when he was brought to Wagner's Clinic during one of these attacks.

While under observation it was found that the attacks commenced with twitchings in the left facial region, extending to the upper and lower extremities; next attacking, first, the right lower extremity, and then the upper;

finally, unconsciousness supervened with general convulsions.

The lower end of the central convolution was diagnosed to be the seat of the lesion. He was transferred to Wernlechner's wards on April 2nd for operation.

On opening the cranium at the point specified a large cyst about the size of a walnut, of a bluish colour, filled with clear fluid, was met with. After draining and cleaning out the space the wound was closed, and the scalp brought together. A few slight attacks occurred since the operation, but they soon ceased altogether. "Facial innervation" is now perfect.

It is presumed that this cyst was the result of a hamorrhage from the contre-coup, which led to cerebral spasm, and finally determined a disposition to epilepsy.

VAGINAL HEAT DOUCHE.

Hirtl showed an apparatus for supplying heat to the vagina, its principle being a practical form of utilising the heat given off by fluid substances passing into crystallisation. A compress is steeped in liquid acetate of soda and this is placed in the vagina, where it will maintain a temperature of 58 degs. Cent. or 146.4 degs. Fahr. for five hours, this being the crystallising point of sodium acetate.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Excision of the Tongue for Epithelioma.-Mr. JOHN MURRAY operated on a man, æt. 51, who had been admitted for epithelioma of the tongue. The patient suffered from syphilis at the age of 16, and was then treated for six months. Seven years before the present time he noticed his tongue was painful and that there were little white patches on the left side. This condition remained unchanged till about a year ago when A month before the tongue became more painful. admission he noticed a groove on the left side of the tongue, and a week later a swelling appeared on the left side of his neck. On examination the whole of the left side of the tongue and part of the right was covered with white thickened epithelium. On the left side at the junction of the middle with the posterior third there was a large irregular ulcer with hard indurated base and everted edges. The floor of the mouth was not involved and the tongue was only slightly fixed. Several enlarged glands could be felt lying along the anterior border of the sterno-mastoid, and just below the angle of the jaw. A preliminary laryngotomy was performed to facilitate the administration of the anæsthetic, and to prevent any trickling of blood into the larynx. An incision was then made commencing just below the symphysis menti, carried down on the left side to the great cornu of the hyoid bone, and then upwards along the anterior border of the sterno-mastoid just below the lobule of the left ear; the skin, fascia, and platysma were divided, and the flap thus formed was raised and turned up over the face. Several enlarged glands lying over the carotid vessels were removed. The external carotid artery was then exposed and ligatured between the origins of the superior thyroid and lingual arteries. The submaxillary and sublingual salivary glands were next removed. A suture was then passed through the tip of the tongue, the organ drawn forwards, and a sponge, with a silk thread attached, passed into the back of the pharynx, a

Fergusson's gag having been placed in the mouth. The tongue was drawn forwards, and the mucous membrane of the floor of the mouth divided with scissors on each side quite close to the lower jaw. The tongue was now split, and the right half was removed with the scissors through the mouth, the lingual artery on that side being secured after division. The tissues were then separated from the lower jaw on the left side, and the left side of the tongue drawn out through the wound in the neck after the anterior pillar of the fauces had been divided, and the remainder of the tongue cut away with the scissors just in front of the epiglottis. A few small vessels only required ligature. Two sutures were introduced, uniting the stump of the tongue to the cut mucous membrane of the floor of the mouth. The skin flap was then replaced, united by points of interrupted suture, and a large drainage tube inserted at the centre of the wound, passing into the mouth. Dressings were applied, and the surface of the stump of the tongue and floor of the mouth were brushed over with Whitehead's varnish. Mr. Murray remarked that the case was evidently one of epithelioma of the tongue supervening on a chronic superficial glossitis, probably the result of syphilis. He pointed out that in such a case, where glands were involved, an operation such as the one he had just done afforded the patient the best chance, as it enabled the surgeon to clear out thoroughly all the glands likely to be affected, and also to remove the tongue more completely. The preliminary laryngotomy, he considered, facilitated the operation very materially. In the first place it allows the anæsthetic to be more easily administered, obviating the likelihood of the patient coming round and struggling during the operation; secondly, with the sponge in the pharynx, all anxiety with regard to blood trickling down into the larynx is avoided, and the surgeon is, therefore, enabled to perform the operation more deliberately. With regard to the ligature of the external carotid, he said it was more simple than ligature of the lingual and facial separately, and whilst it prevented hæmorrhage more efficiently it did not in any way add to the risk of the operation. He also dwelt on the importance of being able to perform such an operation in a bloodless manner, as it enabled the operator to see clearly the limits of the growth, and thus to avoid cutting too near diseased tissue; this he considered a most important point. With regard to the lingual artery on the opposite side, in the absence of any cancerous disease affecting the right side of the tongue, and there being no evidence of any enlarged glands of the neck in that side, he did not think ligature of the lingual artery in the neck a necessary procedure, as the vessel could be easily secured after division of the tongue. The whole tongue was removed, he said, not only on account of the extensive growth, but also because of the chronic superficial glossitis which affected the right side. He thought that splitting the tongue and removing the right half through the mouth was easier than removal of the whole though the wound in the neck as recommended by Kocher, and it also enables the surgeon to draw the affected side further out of the wound, and thus get more completely behind the disease. In this case the tongue was removed so far back, he said, that the mucous membrane in front of the epiglettis could only be very imperfectly approximated to the mucous membrane

attached to the lower jaw, but that the sutures so introduced would diminish considerably the extent of surface left to granulate, and also prevent any tendency to falling back of the stump of the tongue. The laryngotomy tube would be left in for 24 hours, and the subsequent treatment would consist in irrigating the mouth frequently with Condy's fluid, swabbing its floor with boric acid solution and painting it with Whitehead's varnish. The patient would be fed by nutrient enemata for the first 24 hours, and after that he would feed himself by means of a rubber tube attached to the nozzle of a feeding-cup.

It is satisfactory to record, five days after operation, that there has been no rise of temperature, that the external wound has healed, excepting at the site of the drainage tube, and that the patient got up for a few hours on the fifth day.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 12, 1899.

MEDICAL EXPERTS IN CRIMINAL CASES. THERE are two very different methods of utilising expert medical evidence in criminal cases, one, the French plan of referring the matter to an expert whose duty it is to advise the Court on the points submitted to him—a plan which, in practice but too often converts the expert into a prosecutor-and the other, which obtains in this country, where experts occupy no official position, but come forward at the behest of the prosecution or of the defence and state their views, leaving it to the jury, guided by the judge, to decide which evidence is most deserving of credence. Each plan has its advantages and its drawbacks. The French plan, theoretically at any rate, appears best calculated to secure an impartial opinion by a person of recognised eminence, but in practice the medico-legal expert but too often follows the lead of the brow-beating juge d'instruction

and strains every nerve to secure a conviction, with the result, in certain notorious instances, of misleading the jury by expressing as certainties what ultimately proved to be little more than conjectures. Such a scandal has this become that public opinion in France is rapidly veering in the direction of abolishing the official expert in favour of a plan which would prove less harsh towards the accused, who, under the existing régime, is placed in a very disadvantageous position, seeing that he is not represented at the autopsy and is not afforded any facility for rebutting the conclusions arrived at by the official experts-It is only when the expert displays hesitation that the technical evidence the accused may be able to call can have any weight. Our own plan, on the other hand, is admittedly by no means free from objection. To expect an untrained jury to decide between conflicting views of a highly technical nature is obviously absurd, and even the judge is not much better off. Both judge and jury in arriving at a decision must be to a great extent guided by the professional status of this or that expert witness, so that it reduces itself to a question which side can secure the services of the most eminent expert. This makes it largely a question of means, and as the prosecution is naturally best provided in this respect the accused person is here again at a disadvantage when called upon to rebut conclusions unfavourable to him. This feeling has led to the expression of a desire to see appointed a medical assessor who should assist the judge just as other experts do in matters affecting nautical questions. However disguised this proposal may be, however it really involves the substitution of the plan which has failed to give satisfaction in France, and it must be looked upon with suspicion accordingly. There is a third plan which might possibly be found to unite the advantage of both systems with a minimum of their respective drawbacks, viz., the appointment by the Court of an expert for the defence and an expert for the prosecution who would carry out the investigation together, and would agree as to the conclusions to be drawn from the results of their mutually conducted inquiry. In the event of a disagreement a third expert, also appointed by the Court, would be requested to adjudicate upon the points of difference. In this way the jury would not be confused by contradictory reports and inferences, but would merely have to register certain conclusions unanimously arrived at, and which would, in any event, represent the views of the majority of the Court of experts. In the first place, there would necessarily be complete agreement as to the data, since actual observation does not lend itself to any great divergence of opinion. The conclusions which these data warrant would have been discussed, and the personal equation would be eliminated. We should then be spared the spectacle of one authority stating in open court that ergot, for instance, is an abortifacient, while another, possibly not less eminent, absolutely denies that ergot will bring about abortion in the early stages of pregnancy. Under the system we have described, this point would have to be

threshed out, not on the strength of other fallible authorities, but by actual experiment, failing which the weight of opinion would be against the witness who advanced such a view without being able to allege facts which must convince his dissenting colleague. The extreme indulgence which characterises the administration of English criminal law as towards the accused robs the present system of much of its barshness; but it is, in our opinion, fully as desirable to secure the conviction of the guilty as to facilitate the escape of the innocent. The present system which involves an endeavour to confuse the minds of the jury by pitting conflicting views against the conclusions of the expert for the prosecution undoubtedly in many instances enables the guilty to escape in virtue of the principle that the prisoner is entitled to the benefit of the artificially created doubt.

THE LORD CHANCELLOR'S NEW ACT.

THE Bill lately introduced by the Lord Chancellor has emerged from its first reading in the House of Lords, and will almost certainly pass through its further stages rapidly enough before being submitted to the Commons. Its intention is to prohibit the profession of a physician, surgeon, dentist, or midwite being carried on by a company. The operative clause, to which we called attention a fortnight ago, runs thus:-" It shall be unlawful for a company under the Companies Act, 1862 to 1898, to carry on the profession or business of a physician, surgeon, dentist, or midwife, and if any company contravenes this enactment it shall be liable on summary conviction to a fine not exceeding £5 day during which the contravention for every Clearly the principle involved in this happens." clause, if carried out into legislative form, must have an important bearing on the medical profession. Unfortunately the field of action is limited to companies, and it is not always an easy matter to say what is or is not a company. The first instance that will occur to everyone is that of the advertising dentist companies which carry on business on a large scale. When a company simply employ a qualified practitioner to attend to servants or passengers, and where no pecuniary profit is made by the employers out of his services, the new Act could obviously not be meant to apply. There is another large class of cases, however, where a company makes a direct profit upon the work of the salaried medical officer, and there the Act would probably interfere. In that event, a severe blow would be at once aimed at the many proprietary medicine companies that employ a qualified practitioner to interview and advise their customers. As things go, if such a man be deprived of his qualification he can still go on working for the company, but the Lord Chancellor appears to have shifted the attention of the Legislature from the wretched tools of the patent medicine directors to the fountain head. But the majority of our readers, on hearing of the Bill, will at once ask themselves how far the Medical Aid

Societies will be affected. The question is a burning one in the medical world, and its solution must sooner or later inevitably be forced upon the community. If relief should come unexpectedly from the Lords so much the better, but it seems likely, judging from past experiences, that the triendly societies will contrive to fall without the operation of the Act. But, on the other hand, if it be wrong for a company to carry on the business of a surgeon for gain, it can hardly be right for another association formed to confer distinct advantages upon its members to make profit out of a medical man. Imagine for a moment the proposal being made that the friendly societies should be allowed to employ the services of a duly qualified solicitor for the benefit of their members, what would the Legislature say to such a scheme? Yet the difference between the professions of medicine and of law in relation to the friendly societies is very much that 'twixt tweedledum and tweedledee. Whatever the ultimate fate of the Chancellor's Bill may be, whatever the changes that may take place in its passage through the Lower House, we may at least be thankful that the attention of all branches of the legislature has been pointedly drawn to the many rank abuses affecting the honourable calling of medicine. In some respects the new Act may be said to eke out and to remedy defects in the existing medical Acts. On the face of it there seems to be little doubt that a properly framed Medical Act would do away with any necessity to forbid a company from practising medicine in any of its branches. There is one point to which public attention may perhaps be drawn. Not long ago there was a discussion in the House of Commons as to the desirability of members holding posts as directors in companies, the interests of which would be likely to be discussed by Parliament from time to time. It will be a matter of considerable importance to ascertain how members of both houses are concerned more or less directly in patent medicine companies To many the mere suggestion of such a possibility may seem sacrilegious, but against that emotion we may state the fact that a well-known member of the House of Commons, who was for a long time a prominent figure in London administration, not many years ago held a seat on the directorate of a notorious quack medicine. His voting on the subject of the regulation of medical training by companies will be followed with interest by those acquainted with the facts of the case. At the same time, it would be more reassuring for the future of medical legislation if such interested members could meantime be excluded from voting when such measures are submitted to the Legislature.

LEGISLATION AGAINST TUBERCULOSIS.

In view of the movement now on foot regarding tuberculosis, the time seems to have come for considering whether or not it would be expedient to bring forward some legislative measure with a view to the prevention of the disease

In this connection doubt may be expressed concerning the present methods of protecting the public from the disease being sufficiently comprehensive to attain the object in view without the assistance of direct legislative interference. In other words. under present circumstances any measures, undertaken for the prevention of tuberculosis are only carried out voluntarily; they do not belong to that category of compulsory injunctions provided for by law, and all, therefore, that public health authorities can do in the matter is simply to warn the public that tuberculosis is an infective disease, against which it is essential to adopt certain precautions. No doubt, in time, the good sense of the people will lead themto adopt the advice proffered, thus dispensing with the need for compulsion. time, too, the knowledge of tuberculosis as an infective disease will probably become generally disseminated, and by this means less difficulty will be experienced in making persons understand the necessity of observing the precautions brought under their notice. Meanwhile, however, certain impatient sanitarian enthusiasts are busily advocating a Tuberculosis Bili dealing with all the points concerning the prevention of the disease upon which authorities are agreed. There cannot be two opinions concerning the urgency of taking measures to prevent the dissemination of the disease; but we are hardly, as yet, in a position to affirm that, if such measures are to be successful, they must necessarily be compulsory. A matter of such importance, it may be urged, should not be left to the free will of the community, and it must be conceded that if the latter policy had been adopted in regard to small-pox, and vaccination had not been made compulsory, it is impossible to doubt that the freedom which this country has enjoyed for many years past from small-pox would never have been attained. So far as legislation against tuberculosis is concerned, there are, of course, many points which would have to claim attention. In the first place, the opinion seems to be gaining ground that, as an infectious disease, it ought to be made notifiable. Again, as an infectious disease, legislation would have to provide for the free disinfection of dwellings occupied by persons who have succumbed to the disease. Recognition, too, would be necessary of the evil of expectorating in public streets, conveyances, or places, and prohibition of the habit, if possible, enforced. Lastly, we are asked to consider the necessity for public sanatoria throughout the country for the treatment and care of tuberculous patients, for this complementary measure would, of course, come within the purview of the Bill. Just in the same way as lunatics are provided for in public asylums, so, according to the advanced school of sanitation, accommodation would have to be forthcoming for tuberculous persons, and thus the system of the prevention of the disease would be under legislative control, to the benefit, we are assured, of the community generally The above suggestions upon the subject, however, are a mere outline of the direction in which, it is suggested that legislation would be useful. One main point in these remarks has been to draw attention to

a matter which now seems to call for earnest consideration. Much valuable time might be gained in the crusade against tuberculosis were compulsory measures to be introduced in the near future for arresting its dissemination, while, on the other hand, to temporise with such an evil as that under discussion, by failing to recognise the urgency of dealing with it vigorously, would be to display a singular want of wisdom.

Rotes on Current Topics.

A Hint to Nervous Candidates.

Few probably are the candidates who at one period or another of their student career have not experienced the classic indisposition engendered by the imminence of a mauvais quart d'heure to be passed The bladder before unsympathetic examiners. becomes irritable, and in this condition the bowels may participate. In addition to these distressing phenomena there is often a feeling of extreme abdominal malaise and tumultuous throbbing of the heart, which may even be associated with faintness; this group of symptoms we are invited to attribute to relaxation of the abdominal muscles consequent upon the diversion of nervous energy to other parts of the economy. This relaxation of the normally tense abdominal walls, we are told, favours the accumulation in the large abdominal veins by gravitation of an undue proportion of the circulating blood provoking local plethora and coincident cerebral anæmia, while the heart beats loudly and forcibly in a mad attempt to maintain the circulation with an inadequate supply of the fluid. As to the existence of cerebral anæmia no doubt can exist, evidenced as it is by a tendency to incoherence of ideas and an inability to concentrate the mind on any given subject, in addition to more or less impairment of memory, occasionally amounting to temporary abolition of that important function. This hypothesis has much to recommend it, even in the absence of a postmortem examination on the body of a student who has succumbed to an unusually violent attack. The proper treatment is evidently to reinforce the abdominal muscles, and for this purpose nothing answers better than a tightly drawn belt. On reflection many of our readers may be able to recall an instinctive desire to "gird up the loins" by drawing the trousers strap tighter just before undergoing the ordeal. Anyhow, the procedure is one worth trying by nervous candidates. It will not, it is true, confer a knowledge of the subject which has not been acquired, but it may enable the cerebral circulation to be carried on with something like physiological lines, and thus enable the candidate to make the best use of such knowledge as he has obtained.

Last week there were 3,599 patients under treatment in the district hospitals of the Metropolitan Asylums Board, being a decrease upon the preceding week of 62 in the scarlet fever, 47 in the diphtherial in the typhus fever, and 23 in the enteric fever admissions.

A Medical Club in Paris.

MEDICAL clubs in England, that is to sav. clubs provided solely for medical men, have been repeatedly organised in the past, but have always proved dismal failures. The last one of the kind, we believe, which was started hung on to life for a time, but it died of inanition, and its end was rendered somewhat notorious by the suicide upon its premises of one of the members. However, apparently in ignorance of the unclubable characteristics of medical men towards each other-quite natural, we imagine, under the circumstances-efforts are being made to found a "Club Medical" in Paris. The idea is by no means a new one, but its realisation at the present time is due to the approaching Universal Exhibition in Paris, and to the fact that besides other attractions for medical men, the meeting of the International Medical Congress will be held in Paris at the same time as the Exhibition. It is also pointed out that last year Dr Lassar founded the "Club de Médecins" in Berlin, which now numbers four hundred members, this being regarded as an additional reason for following the example in Paris. The Gazette Médicale de Paris discusses the whole project in a recent issue, and has much to say in its favour. On paper the scheme has a most attractive appearance, but whether it can succeed in practice is open to considerable doubt-Medical men have abundant opportunities of meeting each other without resorting to the surroundings of a medical club, where their bete noire "shop" would always obtrude itself into discussions.

Southwark Guardians on Dissecting.

GUARDIANS as a general rule display more sentiment as regards a dead than a living pauper. In this curious attitude they remind one of the Chinese, who treat human life as a worthless trifle, but to whom a corpse is hallowed and sanctified, an object of tender care and costly solicitude. This spirit seems to have possessed the Metropolitan Board of Guardians of St. Saviour's, Southwark, if we may judge from a recent discussion which took place in that august assembly. The occasion was a motion brought forward by a member to the following effect: "That the steward of the infirmary be instructed to cease sending the bodies of deceased inmates to the School of Anatomy for the present; that inquiries be made of the authorities of the School of Anatomy as to how the bodies sent to them by the guardians are ultimately disposed of, and whether their use is strictly confined to medical and surgical research." The gentleman who advanced this proposal professed that he had no wish to stand in the way of science, although, so far as can be gathered from the report, he failed to point out how practical anatomy was to be learnt without bodies. His alleged motive was to prevent the remains of unfortunate persons from being dealt with in the disgusting manner they were at present by many medical students. It would be interesting to hear further details of the dissecting-room stories upon which his ridiculous action has been founded. In all such places with which we have been acquainted the practice has

Digitized by Google

invariably been to remove all remains in a coffin for burial; but, at the same time, it may be remarked, in passing, the better plan would undoubtedly be to use cremation. The first portion of this wiseacre motion was ultimately withdrawn, and the second carried unanimously. The deans of medical schools will be glad to learn that there is no immediate prospect of the stoppage of the supply of subjects for their dissecting-rooms.

Clearing a Crypt of its Bishops.

THE long-delayed Home Office Order has been issued forthwith to clear the crypt of St. George the Martyr, Southwark. This peremptory document has caused no little commotion among the powers that be in the locality of South London, chiefly, so far as can be gathered, because the cost of removing the two thousand coffins, more or less, will involve a substantial addition to the rates Burials have been going on continuously in this crypt for some centuries, and among the bodies are supposed to be those of Bishops Bonner and Gardiner, the Duke of Suffolk, Cocker the Arithmetician, and many distinguished debtors, if the phrase be permissible, from the adjoining Marshalsea The proposal to re-bury the remains of the above-mentioned persons in the churchyard has raised a storm of opposition from the Radical element of the Vestry, who claim with strident voice that no distinction should be made in the case of the "blue-blooded" Bishops. For our own part, without going into the question of the desirability of maintaining social distinctions under such circumstances, we should be inclined to think that the best way of disposing of the remains on grounds both of efficiency and of economy would be by means of cremation. Some time ago the view was advanced that the church, which had received large burial fees for the disposal of bodies in this undesirable manner, should be called upon to bear a portion at least of the cost of removal, an argument that appears to have hitherto remained unanswered. It is to be hoped that the good sense of the Vestry will lead to a satisfactory solution of this costly problem, which, it may confidently be asserted, will not be allowed to arise again in the more enlightened sanitary times in which we are at present placed.

Tattooing.

An inquest was recently held in London on the body of a man who had died of blood-poisoning three days after being tattooed by an expert in that department of pictorial art, but the evidence did not appear to prove any connection between the operation and his untimely decease. Judging from certain statements that have since appeared in the Press, it would seem that tattooing is becoming, or has already become, a fad in certain sections of "society." One expert declares that he has tattooed no less than 400 medical men in London alone, but the practice seems to be popular also in military circles. What possible object the subjects can have in view

in getting themselves decorated in this fashion it is difficult to conceive, and it must not be forgotten that the practice when performed in the usual way is not unassociated with risk in consequence of the use of unclean implements and neglect of antiseptic precautions. There are plenty of instances on record in which blood-poisoning, syphilis, and other communicable diseases have been conveyed in this way, even if we admit that in the particular instance referred to the blood-poisoning was post hoc and not propter hoc.

Proposed Extension of the Compulsory Notification System.

A BILL intended to make the adoption of the Compulsory Notification system by sanitary authorities which have not voluntarily adopted it is going through the House of Commons and is likely to pass this session. The only serious opposition to it will come from those authorities which see no commensurate return for the somewhat heavy cost which the working of the Act incurs, and for the amount of squabbling which it imports into the district. Neither of these reasons need trouble such authorities much. If the system is forced upon them they must adopt it in name, but can ignore it in practice if they choose, as a majority of sanitary authorities have done. Whether they have to pay much or to endure much wrangling depends chiefly upon the Superintendent Medical Officer of Health, who, if he bean enthusiast, may plunge his community into outlay and all sorts of altercations, and, if he be not, may pass the system by with a distant nod. It is satisfactory to note that the experience of the notification system for years past has taken most of the edge off the zeal of the ultra-sanitarians. We hear little now of the carting off of patients, willee-nillee, to isolation hospitals. If they get there at all it is, as it ought to be, by persuasion and gentle pressure, and not, as some suggest, by policemen and handcuffs.

Friendly Societies and the Profession.

At the annual conference of the Friendly Societies Medical Alliance the recent agitation within the profession against the abuse of medical aid came up for discussion, and some alarm was expressed at the prospect of action by the General Medical Council in the direction of treating medical men associated with such associations as guilty of "infamous conduct in a professional respect." There is, we imagine, little probability of such an extreme measure, but other means will certainly be found of bringing pressure to bear on aspirant medical officers unless the societies in question consent to introduce certain much needed reforms. One of these is certainly a wage limit, and in this respect we regret to see that, according to the President, "they would always strenuously resist any claim put forward by the medical profession to impose any wage or other limit to membership of such societies." If this attitude be persisted in it will mean war to the knife, and we have little apprehension as to the ultimate victory of reason and

common sense, backed by co-operation on the part of members of the same profession.

A Side Wind at the Royal College of Physicians, London.

An esteemed correspondent, a prominent Fellow of the Royal College of Physicians, London, writes to us taking exception to the comments which appeared last week regarding the election of the President of the College. As the questions raised in his letter are of no little importance, we deem it right to publish the following quotation thereof. He says: "In the election of the President of our college the other day, there was no idea of St. Mary's and St. Bartholomew's. If Sir W. Broadbent had not lent himself to mixing up Royalty and the public in the question of the openair treatment of tuberculosis in a manner many of us think unseemly and unprofessional, not to say worse, he would have been chosen. We have had too much of the Prince of Wales and hospitals, and no good effect has resulted. A certain class of people in this great city will follow the Prince, but they are not the class to whom we look for much help in true charity or true progress. The example of the Prince has not been a good one in many ways, and to make use of His Royal Highness to boom some such scheme as 'open-air treatment' for the benefit of a clique is not regarded by many of the Fellows of the College as creditable to our profession." We do not give publicity to these expressions of opinion solely because they represent the feeling of our correspondent, but because we are given to understand that they are shared by a considerable number of his colleagues at the college. As such, therefore, they undoubtedly claim attention. As we have more than once said in these columns, it is a matter of sincere regret that the Prince of Wales should allow himself to be so exploited in the present day in connection with hospital and other schemes, the expediency of which fails to appeal to the community, but this only shows the genuine good nature of which His Royal Highness is the possessor.

Dirty Railway Carriages.

UNDER the new Public Health Act for Scotland powers are conferred upon local authorities to secure cleanliness in "public conveyances plying within their districts," and we are glad to see that these powers are about to be put in force to compel the railway companies to improve the sanitary condition of their rolling-stock for passengers. The sanitary inspector to the Perth County Council, for example, has especially called the attention of his council to this matter, and points out that in certain cases he found the carriages in a very filthy state, the cushions being thickly charged with dry dust, and the floors in an offensive condition. He also animadverts upon the common practice of guards and others in charge of passenger trains closing the doors and windows of carriages waiting for departure at stations. No doubt this practice may be dictated by the desire to preserve the railway property, but it is by no means conducive to the health of the travelling public. In the interests of the

latter, free ventilation should be allowed through the carriages when not in use. There is no disputing the fact that the question of keeping railway carriages clean is a very important one, especially in view of the long-distance journeys provided by the trunk lines. To pass many such hours, for example, in a tuberculous-laden atmosphere of a railway compartment would be likely to be highly prejudicial to a delicate passenger. It is, however, obviously the duty of the various companies to see that their passenger rolling-stock is kept in a clean and sanitary condition, even if that should involve, as has been suggested, the substitution of the present carpeted floors and cloth-cushioned seats of the compartments for floors lined with linoleum, and strong leather cushions.

"Anomalies of English Medical Education."

UNDER this heading a curious deal of discussion has of late taken place in the columns of our American contemporaries, and some remarkable opinions have been expressed upon the subject. We can quite believe that on the other side of the Atlantic the various portals by which English medical students can obtain their qualifications provide a puzzling problem to those who attempt to solve it. But this scarcely affords an excuse for the editor of a journal who falls astray in his efforts to explain the intricacies of the system to his readers. The editor of the Journal of the American Medical Association, for example, in replying to a correspondent, shows that he has not informed himself in regard to the F.R.C S. and F.R.C.P. He gives it as his opinion that the "degrees (sic) are to a certain extent honorary, although not entirely so." In the first place these distinctions are not degrees, but diplomas, and to describe them in any sense as honorary is misleading. The former is made most exclusive by reason of the stringency of the examinations by which its portal is guarded, and is essential to all surgeons aspiring for hospital appointments, and the latter is perhaps more jealously guarded still, and is only conferred upon those who has proved their worth after serving a long apprenticeship as members of their college. But all the information upon this and kindred subjects is concisely set forth in the Students' Number of the MEDICAL PRESS AND CIRCULAR which appears every September, to which we may refer our American contemporaries.

Oigarettes Banned in Arkansas.

THE American tendency towards prohibition law is proverbial, and is, not without some show of reason, attributed by some authorities to the inherited instincts of the parent stock of Puritans. Some of the latest departures have been of a remarkable nature, and seem calculated to try to the uttermost the patience of a long-suffering populace. In Maine, so it has been reported, the legislature have issued a sumptuary edict against the wearing of stays by women, a regulation that carries on its face the stamp of righteousness, but is nevertheless calculated to stir up a revolution in any society of self-respecting women. The Government that could frame such a

law must indeed be conscious of a strength even passing that of the average empire, which would infallibly collapse like an eggshell under so great a strain, In the State of Arkansas another law has been enacted abolishing the selling or giving away of cigarettes, under a penalty of not less than £100, and not more than £1,000. This step has been taken on the ground that cigarette smoking is deleterious to health, and to a certain extent that assumption is undoubtedly true. Excessive smoking in any form is harmful, but less injury is done by indulgence in pipes than in cigars, while cigarettes stand easily at the head of the black list. Fortunately, for the most part, as men grow older and less organically strong, by a natural process they diminish or discontinue their indulgence in the weed nicotiana, and so is brought about by easy physiological adjustment what the good folk of Arkansas seek to establish by the strong hand of the law. Fancy how free Englishmen would receive such a statute; it is likely that within twenty-four hours of the passage of a Bill of the kind the country would be aflame from one end to the other.

Physicians and Charity.

THE will of Sir William Jenner was proved last week, the gross estate amounting to £385,083 18s.5d. Under the will the Royal College of Physicians, London, will benefit ultimately to the extent of £10,000, and thus their ex-President is likely ever afterwards to be held in kindly remembrance by the Fellows of the College. It is, however, somewhat strange that Sir William Jenner, out of the abundance of his wealth, should have left nothing to the hospital with which he was so closely connected for so many years of his life. University College Hospital has ever been in dire straits financially, in order to carry on its work, and a bequest from its celebrated consulting physician would no doubt have been most thankfully received. A propos of this subject we are reminded of the absence of bequests to their respective hospitals in the wills of Sir William Gull and Sir Andrew Clark, each of whom left a gross estate of upwards of half a million. But neither Guy's nor the London Hospital profited financially by the death of these distinguished physicians, although it is, perhaps, only true to say that the foundations of their immense fortunes were laid as the result of their connection with these institutions.

Is Registration an Essential Precedent of Medical Practice?

It will be recollected that, in the autumn of last year, Mr. Victor Horsley, one of the Direct Representatives for England in the General Medical Council, propounded a theory that, under the terms of the Medical Acts, no one could lawfully practice without registration as well as qualification. Mr. Horsley's discovery would have been an invaluable "find" if it had turned out to be genuine, and he gave excellent reasons for believing that it was so. In such case every quack in the Kingdom could be prosecuted for reactising without qualification, and with

much more prospect of success than he can now be prosecuted for representing himself to be registered. It now appears, however, that Mr. Horsley's interpretation of the Acts cannot be substantiated, for the Council of the British Medical Association has obtained the formal opinion of Mr. Haldane, Q.C., and Mr. Oliver Hodges, B.L., who have agreed that the law cannot be so read. Probably Mr. Horsley will not concur in this view, but, for the present, we may take the question as settled.

The Role of the Pericardium.

It is a curious fact that treatises on physiology say little or nothing with regard to the function of the pericardium, though, as a general rule, the authors of such writings do not display any unbecoming hesitation in explaining and commenting upon the intentions of the Creator in respect of tissues and organs. It remained for Mr. Barnard to show that the function of this much-studied but ill-understood serous sac is really to prevent undue dilatation of the heart under the strain of a sudden inrush of blood. It is actually part of the circulatory apparatus in controlling which it plays a very useful role. When we consider the various forces at work in carrying on the circulation, in which the cardiac vis a tergo is perhaps only of secondary importance, it is evident that under the accelerating influence of great muscular exertion, plus exaggerated respiration, the quantity of blood which reaches the right heart must be vastly increased, and Mr. Barnard has shown by actual experiment that if the pericardium be slit up the strain promptly produces a distension of the thin cardiac walls which bulge through the pericardial aperture. This throws much light on the pathology of pericarditis. When the membrane, usually tough and very resistant, is softened by the inflammatory process, it is apt to yield to the pressure from within, created by ill-timed muscular exertion, allowing the walls of the heart to dilate beyond the normal itself undergoing a process of stretching which is probably never recovered from. When it becomes adherent, on the other hand, it hinders normal expansion, and the circulation of blood through the heart is pro tanto impeded. A dilated heart therefore almost necessarily infers a stretched pericardium, though the fact that a dilated heart can to some extent be recovered from under appropriate treatment appears to negative this assumption. In any case we are indebted to Mr. Barnard for a valuable addition to our knowledge of the physiology of the pericardium, which will certainly prove of service in elucidating many moot points in the pathology this region.

THE American papers record as an instance of sympathetic contagion" the death of a girl at St. Louis of cerebro-spinal meningitis, attributed to her having read a highly-coloured description of the symptoms in a local paper. It would be difficult to reconcile this hypothesis with the established fact of the microbial origin of this disease, but of this the writers recked not.

Is Breast Milk Sterile?

MEDICAL writers are apt to assume that the mammary secretion, as it comes from the breast, is a perfectly sterile fluid. Their error is founded on the teachings of a bygone pathology, for it is clear that milk can be contaminated by micro-organisms, both before and during its secretion, or what many would now prefer to term its excretion. The blood-stream may be at fault, and he would be a bold man who would assert that specific pathological microbes may not infect therefrom the substance of the mammary gland and its excretion as they might that of any other excretory organ of the body. Then there is the ever-open door of entry from the outside by way of skin or gland ducts. All this is apart from any visible gross lesion about the nipple, which we exclude and concede reasonably to the upholders of the sterile theory. On the whole, it seems likely that the milk from a healthy mother and a normal breast will be to all intents and purposes, and in the majority of instances, sterile, but that proposition obviously leaves a wide margin of possibilities in a contrary direction. The point is one of great practical importance, both as regards the milk of human beings and of cows. Turn to the case of tuberculosis. Who is to say that the milk of a mother affected with that disease will at no time be contaminated with specific organisms? In not a few cows it is difficult even for a scientific expert to recognise the disease, but it does not follow that an infected beast is not giving off bacilli in the milk which is destined to be used as food for the The position indicated is bovine higher animal. tuberculosis, apart from new growths or ulceration of the udder, which anyone can recognise. The whole question is one of extreme importance in preventive medicine, and it is to be hoped that some competent authority will investigate the matter in its various physiological and pathological bearings.

Glorious Inconsistency.

THE mining doctors in the Newcastle district have combined to ask a more reasonable scale of remuneration than that which has been their lot for the last half century. While in some instances the demand has been cheerfully acquiesced in, in others the associations of miners are busy advertising for medical men willing to work on the old scale. As Dr. E. Jepson points out in the columns of the Newcastle Daily Chronicle, by resorting to this plan the miners are acting contrary to the principles of trades-unionism and are endeavouring to manufacture medical "blacklegs." Consistency, however, is not the most noteworthy attribute of the labouring population, and doubtless they are prepared to claim a monopoly of the organisation of labour. We cannot disguise the reluctance we feel at the introduction into medical practice of methods which, moreover, have not proved an unqualified success in the hands of the very persons who now resent their application to the amelioration of the conditions of medical labour. Qui veut la fin veut les moyens, but it ought to be possible to discover other means than direct com-

pulsion of inducing these worthy people to accede to demands which strike one as singularly moderate and reasonable.

The Agitation against Vaccination.

WE are requested by the hon. secretary of the Jenner Society (Dr. Bond, of Gloucester) to ask such of our readers as are practising in localities in which the agitation against vaccination is acute, either in the form of newspaper correspondence or of public lectures or debates, to be good enough to communicate with him. When newspapers containing reports are sent the article to which it is desired to call attention should be marked.

A PRIVATE Subscription Dance, in aid of a fund to enlarge the out patient department of the West London Hospital, will take place at the Empress Rooms, Royal Palace Hotel, Kensington, on May 17th, 1899.

The death is announced of Dr. William Squire at the age of seventy-three. Dr. Squire's name is well known in connection with the introduction of the salicylates in the treatment of rheumatic fever, and in various departments of preventive medicine.

A GRAND bazaar in aid of the Great Northern Central Hospital, London, is to be opened in the Portman Rooms next month by H.R.H. the Duchess of Albany. Mrs. Kendal and Mrs. Beerbohm Tree have promised to give recitations, and well-known artists will provide dramatic entertainments.

PERSONAL.

THE Earl of Kimberley, K.G., has been appointed by the Queen Chancellor of the University of London, in the place of the late Lord Herschell.

SIR JAMES BELL, Bart., was last week elected, by a large majority, to the assessorship in the University of Glasgow, vacant by the death of Dr. King.

PROFESSOR SCHAFEL, F.R.S., of University College, London, is, we understand, a candidate for the Professorship of Physiology in the University of Edinburgh, vacant by the death of Professor Rutherford.

DR. W. ALLAN JAMIESON, who has been appointed to the newly instituted chair on skin diseases in Edinburgh University is a renowned archer, being the holder of the second largest number of trophies among living members of the Royal Archer Company, who form Her Majesty's body guard in Scotland.

Our congratulations are offered to Professor Robt. Muir on his selection out of eight candidates for the chair of pathology in the University of Glasgow, voided by the lamented death of Professor Coats. Honours appear to fall quickly in the path of the new professor; but a few months ago he was elected to the chair of pathology at Dundee, which post he has now to vacate for the still more important one at Glasgow.

Dr. Roux, Medical Director of the Pasteur Institute in Paris, states that he knows nothing of Dr. Bra, of that city, and does not believe in his alleged discovery of the cancer microbe. Meanwhile Dr. Bra is striving to calm the daily press, begging them to restrict their descriptions of his experiments to their proper proportions.

WE regret to learn that as Dr. Ringwood, of Kells, was recently returning home at night from visiting a patient, he met with a very serious accident. His horse fell and flung him out of a high dogeart on to a quantity of broken stones. In addition to fracture of his right arm, Dr. Ringwood received very severe abdominal bruises, which gave rise to a sharp attack of local peritonitis and cystitis. However, under the care of Dr. Minchin, Kells, he is now progressing as favourably as can be expected.

We understand that the private asylum heretofore conducted by Dr. Patton, at Finglass, near Dublin, has passed into the hands of Dr. W. R. Dawson, Dr. Patton having attained the age at which rest becomes necessary. The establishment has always been, if we may use the phrase, very popular, in consequence of its excellent working by Dr. Patton, and as Dr. Dawson has served four and a half years as assistant, having previously studied at Morningside Asylum, Edinburgh, it may be anticipated that the prestige of the institution will be maintained. Dr. Dawson has held the Stewart Scholarship in mental diseases of the Royal University, and has been a Travelling prizeman in the University of Dublin.

THE UNIVERSITIES DEGREES BILL.

IT will be recollected that this Bill. which is now before the House, aims at compelling all persons who hold foreign University degrees to append to their name graduation titles, the place of origin, e.g., M.D. Brux. for the Brussels degree. General Laurie has placed against this Bill a notice of motion that it shall not pass as long as "graduates of universities in the United Kingdom are exempted from such requirement." We sympathise with both the promoters and the opponent of the measure. The purpose of the Bill is excellent, because it seeks to prevent the holders of sham degrees sailing under false colours in Great Britain, but we do not see why graduates of British universities should hesitate to attach to their names a similar indication of the source of origin. And we think that the principle of General Laurie's motion deserves approval.

THE IRISH CO NCIL ELECTIONS.

The election of County and District Councils under the new Local Government Bill took place last week, and here and there a doctor got a seat. Among them was Dr. Usher, recently retired from the Dundrum Dispensary, and he was elected to the Rathdown District Council. It was, of course, not to be expected that the medical profession would make any decent show on the hustings on this occasion, inasmuch as any medical officers receiving pay were debarred from offering themselves to the electors by what we believe to be a perfectly illegal sealed order

of the Local Government Board, respecting which we may have something to say at a future time.

NEW FIELDS FOR TAXATION.

THE French Government rejected, last week, a proposed tax of 1d. a bottle on mineral waters, but accepted the suggestion that match boxes, which, in France are a State monopoly, should be farmed out for advertising purposes. The reason given by the Minister for refusing the mineral water tax was that soda water is a medicine, but we suspect that the traders in effervescents are politically stronger than those in matches.

TUBERCULOUS MEAT AND MILK.

WE notice with satisfaction that the Royal Agricultural Society has recognised the exigencies of the anti-consumption crusade. It has issued a leaflet to farmers and dairymen inculcating the necessity for special precaution against the sale of tuberculous milk or meat. This is the first step in the education of the public who are materially interested in the question, and we have no doubt that it will produce good results.

THE National Association for the Prevention of Consumption and other forms of Tuberculosis has been registered as a limited company, the maximum number of members being 1,100, and the liability five guineas. The registered offices are at 20 Hanover Square, London, W.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

NEW PROFESSORS IN SCOTLAND. - The Edinburgh School of Medicine has good reason to be satisfied with the honours which have lately been bestowed on her alumni and former members of her teaching staff. years ago the Extramural School provided Professor Stockman for Glasgow University's Materia Medica Chair; St. Andrew's took Mr. Musgrove for Anatomy; Dundee elected Professor R. Muir for Pathology, only to be deprived of his services because of his selection last week by Glasgow University; while Mr. J. A. Thomson, Lecturer upon Natural History and Biology in the same School, was last week appointed successor to the late Professor Alleyne Nicholson at Aberdeen. If we look back a few years further, we find the names of a number of Edinburgh Graduates or Licentiates engaged in the instillation of medical knowledge into students' brains. For example, at least seven of the Professors of the Glasgow University Medical Staff were at one time undergraduates in Edinburgh.

GLASGOW UNIVERSITY CHAIR OF PATHOLOGY.—At a meeting of the curators of the Chair of Pathology, held on the 6th inst., for the purpose of electing a successor to the late Professor Coats, Dr. Robert Muir, Professor of Pathology, University College, Dundee, was unanimously elected from among the eight candidates. The curators present were Principal Story, Professor McKendrick, Dr. H. C. Cameron, Dr. C. McVail, Dr. Ker, and Messrs. J. H. Dickson and James Boyd. Dr. Muir's testimonials were of such excellence that the curators were, so to say, compelled to appoint him. Certainly, it may not be quite a surprise to the Glasgow candidates and students, yet it is a source of lamentation that an Edinburgh graduate should have been elected to this coveted post.

covered post.

THE RESIDENT QUARTERS IN THE ROYAL EDINBURGH INFIRMARY.—The board has listened to the prayers of the staff concerning their proposed alterations in the residency of this hospital, and agreed to a compromise, by which the majority of the residents will still have both a sitting-room and bedroom for their private use, while one or two of the larger existing sitting-rooms will be given to two residents in place of one, as at present. This arrangement is understood to be provisional until such time the managers can see a way to house the resident physicians and surgeons of the future in a more becoming manner. As the resident staff is mostly drawn from the ablest students graduating in the summer preceding their term of office, those who indulge in the common habit of regarding it as consisting of rowdy boys, for whom any sort of

THE MEDICAL PRESS.

accommodation is good enough, and no amount of disciplinary government too much, or too derogatory, have hereby received a deserved rebuff. THE last six months have produced rather over £28,000 in legacies and donations in favour of the Royal Edinburgh Infirmary. At present Edinburgh students fill the following chairs:—Practice of medicine, anatomy, physiology. zoology, and natural history, materia medica, and pathology. We refer, of course, exclusively to the medical chairs. Dr. Muir will enter on his duties on the

25th at a salary of £1,100 per annum.

New College for Women.—Sheriff Johnston, Q C has presented his final report to the Second Division of the Court of Session on the petition of the trustees of the late Dr. Henry Muirhead, of Longdales and Bushymills, Lanark, to settle a scheme for the founding and maintenance of an institution in Glasgow for the instruction of women in physical and biological science. It is proposed to acquire a property in the immediate neighbourhood of the Victoria Infirmary, with a view to fitting it up as a residential college for the teaching and boarding of female students. The institution is to be known as the Muirhead College.

GLASGOW HEALTH DEPARTMENT -The health committee have adopted the following recommendations submitted by the sub-committee charged with the duty of considering the whole question of the administration of the department consequent upon the resignation of Dr. J. B. Russell, viz.: 1st, That Dr A. K. Chalmers be continued as Medical Officer of Health of the city, and that his salary as such be increased from £500 to £700 per annum as from and after the date of Dr. Russell's demission from office. 2nd, That in the meantime no assistant to the medical officer be appointed. 3rd, That, however, a person having knowledge of bacteriological and chemical research should be appointed to devote his time mainly to laboratory work. 4th. That the appointment of assistants to the Physic an Superintendent of the Hospitals should be made by the Physician-Superintendent, subject to the approval of the Medical Officer of Health. 5th, That in all other respects the administration of the Health Department be continued in accordance with the practice that has hitherto prevailed.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday evening last, April 10th, was devoted to the exhibition of living subjects. them was an interesting case exhibited by Dr. G. Herman of a woman who in 1894 developed a cancer of the right breast, which was removed, with the axillary glands, by Mr. Lawson. It recurred, and was again operated upon. When Dr. Herman saw her in July, 1898, there was a large cancerous ulcer on the right side, with a tumour measuring three inches across in the left breast, and enlarged glands in the left axilla. Oophorectomy was performed and thyroid extract given, and by October of that year the ulcer had healed, the tumour in the left breast had disappeared, and the glands in the axilla could no longer be felt. He mentioned cases to show that oophorectomy alone had not proved very successful, and thyroid extract alone had given no results worth speaking of.

inclined to the view that such improvement as took place was the result of the cophorectomy adding that to be of service it must be done before menstruation had ceased. He mentioned certain other cases to show that cancer might undergo spontaneous cure without treatment of any kind.

APRIL 12, 1899.

Mr. G. R. TUENER observed that even if only temporary the results were none the less very remarkable.

Dr. HERMAN, in reply, admitted that the cancer in disappearing might have left traces, but denied that clinically, at any rate, the nodules could be regarded as cancerous. He pointed out that the results of the com-bined methods were indisputably superior to those of either procedure separately.

Mr. BATTLE showed a second patient, a woman, in whom he had successfully performed gastrostomy by Albert's method for obstruction of the ceophagus.

Mr. G. R. Turner showed a man with a history of syphilis, a sailor, who had fractured the left humerus, followed by non-union, a subsequent operation to promote union being equally unsuccessful. He had cut down and wired the fragments, giving at the same time anti-syphilitic treatment, but still union did not follow. Another operation proved more successful, and the man resumed his occupation. Later on, however, he had once more fractured the bone, and this time operation proved unsuccessful, and he discussed the possibilities of treatment under these circumstances.

Mr. JAFFREY showed a young man who, after two falls, followed by concussion of the brain, had become unable to answer questions, except with difficulty. When asked a question he put his left hand to his mouth, and was apparently convulsed for some seconds before finding

expression, not, however, losing consciousness.

The PRESIDENT, who knew the patient, pointed out that he had been subject to epilepsy before the accidents, and he was inclined to attribute the symptoms to shock, rather than to any injury to the brain.

Correspondence,

We do not hold ourselves responsible for the opinions of our correspondents.

THE LISTERIAN RITUAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Mr. Lawson Tait, in his letter referring to the Listerian Ritual, as he is pleased to designate it, says:
"To claim sulphurous acid as a part of the ritual is as
reasonable on the part of Mr. Bowreman Jessett as if he
claimed the sun and the moon."

I confess I am unable to follow Mr. Tait's argument; but will he deny that sulphurous acid is a strong antiseptic? Whether the sun and moon have equally powerful antiseptic properties, I cannot say, possibly Mr.

Lawson Tait has ascertained, and will explain.

The question I asked Dr. Bantock was based upon a practice I had seen him adopt, viz., syringing out abscesses in the abdominal cavity caused by stitches, which practice he told me he found most useful. I asked him, if he did not believe in Listerism, why he used this powerful antiseptic lotion instead of plain water?

I am, Sir, yours truly,

FREDERICK B. JESSETT.

23 Brook Street, London, W., April 6th, 1899.

OF PRACTICABILITY REMARKS ON THE STATE SANATORIA FOR TUBERCULOUS PATIENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SiB,—If the principles should be established that the chief origin of consumption and its allied diseases is in the contagium of the sputum of phthisical patients, dis-seminated by the wind and finding a fructifying nidus in the comparatively healthy lung, and that it is the duty of the State to prevent that dissemination at any Mr. Stanley Boyd pointed out that there were nodules near the scar which were suggestive of malignancy, and hesitated to regard the patient as cured. He cost, it is manifest that means must be adopted by the

authorities to detect the existence of the infective bacillus in the sputum at the earliest age at which dissemination becomes possible, and to keep strict guard against dissemination by isolating the expectorating patient until he or she shall, by death or otherwise, have ceased to be a centre of infection. We are, for the present, excluding from consideration the local manifestations of tuberculosis such as tabes, meningitis, and joint disease, though it remains to be seen whether sufferers from these forms of tuberculosis do not also need isolation for the safety of their neighbours. Now we are not able to estimate the average pathological life (so to speak) of a consumption patient. He or she may run with headlong speed to the next world, or may drag existence along for half a lifetime, or may even get well altogether, but we do not think that, taking one case with another, five years would be an unreasonably long period upon which to estimate that the State must take peremptory charge of the patient in the proposed sanatorium. Many cases would disappear by death within a few months, and, let us hope, many others would be restored to their families and their breadwinning before the fifth year, but, on the other hand, many hopeless cases, profiting from the benign influence of the sanatorium, would linger on for ten or twenty years in an uncured and infective condition, which would prevent their returning to association with the general public. Now we find that, according to the Registrar-General's returns, the deaths from phthisis throughout the Kingdom (excluding other local tuberculous diseases) number about 60,000 in the year. Assuming that each phthisis case would be a charge on the sanatoria for five years, it is obvious that provision should be made by the taxpayer for 300,000 patients at an initial cost (say 300 sanatoria, each to accommodate 1,000 patients, at the very low estimate of £50,000 each) of £1,500,000 first capital expenditure. Then comes the cost of maintaining these establishments and their inmates, and it is difficult to estimate what this would be, considering that the care and cure of a consumptive involves precautions as to temperature and ventilation and dietary which are not thought of in the case of a lunatic or an ordinary hospital patient. We find that, in one scientifically equipped and economically, though successfully, managed Consumption Sanatorium, each patient costs, for a residence of 119 days, about £14. At Ventnor, the cost is proportionately less, as the greatest period through which a patient is allowed to remain is 98 days, and the average is 53 days. £14 outlay for 119 days means about £43 per head annually, and for maintenance alone. Let us suppose that one-third of the whole consumptive army of 300,000 would be able and willing to pay for their own maintenance, the outlay on the remaining 200,000, the interest and sinking fund on the original capital expenditure being added, would come to very nearly nine millions a year. We have sought to rather undercalculate than to exaggerate the financial burthen involved in a wholescheme of compulsory isolation of phthisical onts. What the amount would be if the other 23,000 patients who die annually from other local tuberculous diseases were included, we should be afraid to say. It is enough to say that, in our opinion, to ask at this juncture Great Britain and Ireland for nine to twelve millions a year would suffice to extinguish for ever the project of State sanatoria. The other difficulties of compulsory isolation seem to us to be even more overwhelming than the financial impasse. Where is the Government which will dare to propose, as has been proposed in America, that every individual heard to cough shall be compulsorily inspected, and, if found to be infected with tubercle, carried off from his or her family and incarcerated, perhaps for years, perhaps for a lifetime! Such a proposal is a legislative impossibility in our country, and we hold very strongly that to clamour for impossibilities is, in all matters of this life, a fatal mistake. The idea may be realised to a great extent by patient education of public opinion, but, most decidedly, not by striving to force Utopian proposals down the throat of the nation.

I am, Sir, yours traly, A. H. J.

Obituarn.

GEORGE CHARLES WALLICH, M.D., F.R.C.S., Id., Surgeon-Major, retired, Indian Army, F.L.S., F.B.S., Liege, &

Dr. Wallich, whose death was announced on the 30th ult. at the advanced age of 83, received his medical education in Edinburgh, and there obtained his F.R.C.S. and M.D. with honours. Soon afterwards he entered the Indian Army, and joined his father, Dr. Nathaniel Wallich. in Calcutta, there well known as a distinguished man of science and an ardent botanist, and for many years in charge of the Botanical Gardens, Calcutta. His son inherited the scientific bent of his father, early displaying a deep interest in the pursuits of natural history, and especially with regard to the microscopic forms of life. On attaining the rank of surgeon-major, he retired from the service and returned to England. He subsequently obtained the appointment of naturalist to the expedition despatched in 1860, under the command of Admiral Sir E. L. McClintock, to survey the proposed North Atlantic telegraph route between Great Britain and America. The information thus obtained of the seabed of the Atlantic proved of great value, assisting much towards securing success for all future works and undertakings of the kind. So much new material had been accumulated by Dr. Wallich, and so many important observations made of the geological formation as well as of the fauna of the ocean bottom, that "my Lords of the Admiralty" saw fit in 1862 to sanction their immediste preparation for publication, stopping that, however, at the first volume. Luckily for science, the Challenger Expedition met with more generous treatment from the Government of a later date, and its accumulation of scientific facts and valuable material have been fully laid open to the public. The work of deep-sea dredging was much facilitated by the improvement he made in the machine previously in use, and whereby he brought animal life from great depths to the surface without mutilation, while his microscopical knowledge assisted much to finally settle the question as to the precise nature of the slimy viscid mud which was brought to the surface. Huxley, in 1858, attached much importance to this ooze, and looked upon it as entirely novel, believing it to be "living protoplasm." Carpenter, who fully studied the same during the laying of the Atlantic Cable ten years later, supported Huxley's view, as also did Professor Hæckel, who even went further and believed it to be "a plasmic substance of spontaneous generation." Whereupon Huxley and Carpenter accordingly named it "Bathybius Hæckelii." This, of course, Wallich proceeded to show was an entire mistake, that the supposed newly discovered substance was nothing more than chalk-ooze common to the Atlantic bed, liquefied by a pressure at some 5,000 or 6,000 fathoms depth.

The discussion for some time waxed warm, but eventually Huxley admitted his mistake. Carpenter, however, never forgave Wallich, and when at a subsequent period friends thought the Fellowship of the Royal Society ought to be bestowed upon one who had done so much good work, Carpenter, it is said, strongly opposed and voted against his admission. Dr. Wallich had undoubtedly a fair claim to the honour, and his rejection embittered the rest of his days. His microscopical work was solid and of great worth, while his researches in Algal forms of life, the Diatomacæ in particular, were of the highest value. He discovered and described many new forms of diatoms as well as Radiolaria, and was the first observer to demonstrate the nucleus and contractile vesicle in Gromia. It would, in short, require much more space than we have at command even to enumerate his extensive and important discoveries.

MR. JOSEPH COPE.

THE remarkable personality of Mr. Joseph Cope, clerk of the Rathdown Union, near Dublin, induces us to depar from usage to refer to his death on Sunday last at his residence in Rathmines from influenza. We shall no be doing injustice to other clerks of Union if we say that

Mr. Cope was their best representative. Not only did he serve the Rathdown Union for nearly fifty years, but for most of that period he was implicitly trusted by a long succession of Guardians of all political colours and all personal characteristics. He was a very able man, knew his business thoroughly, and did it honestly and industriously. Our special relation to him is the part which he bore for many years in the struggle for the interests of the Poor-law officers in Parliament and out of it, in which propaganda he was both earnest and successful. He is deeply regretted by his masters on the Board of Guardians and by all who have been brought into association with him either personally or officially.

Laboratory Rotes.

THE DC.L. MALT EXTRACT.

THE D.C.L. Malt Extract and D.C.L. Extract of Malt and Cod Liver Oil are prepared by the Distillers Company, Limited, Edinburgh. With both we have made exhaustive tests in the laboratory.

The samples of Malt Extract yielded, on analysis, the

following results:— Moisture

28.2 per cent. Total solid residue 71.8

The total solid residue had the following composition calculated in percentages on the original sample:

Mineral matter ... 2.1 per cent. Nitrogenous matter 6.6

Malt sugar ... 60.7

Dextrin, diastase, &c. (by difference) 2.4 ,, The diastatic power was determined by the method

given in "Squire's Companion to the British Pharma-copœia," 17th Edition, page 157.

The result of two series of experiments was that 5 cc. of a 5 per cent, solution of the extract converted a solution of purified potato starch containing 0.5 of a gramme That is to of starch in a fraction under nine minutes. say, this malt extract is capable of converting rather more than double its own weight of starch in ten minutes. This is a very satisfactory result. The diastatic power of a malt extract is a matter of great importance, and as its value largely depends on this characteristic, we strongly urge physicians when prescribing malt extract to insist on their patients taking care to use only an extract of proved efficacy.

The amount of cod-liver oil present in the sample of D.C.L. Malt Extract and Cod-liver Oil was found to be 12 per cent. Both samples are free from undue 12 per cent. Both samples are free fro acidity, and their flavour is exceptionally fine.

STOWER'S LIME JUICE CORDIAL.

WE have, on more than one occasion, had occasion to report on this popular product and invariably in favourable terms. The further sample which, after the lapse of some years, we have received, shows on examination and analysis that it has retained to the full the qualities which induced us to com nend it in the first instance—viz., the absence of injurious impurities, its stability, and, generally, its dietetic properties. Spring is advancing with rapid strides, and the season is close at hand when the cordial will once again be resorted to as a beverage in association with ice and effervescing water. We can confidently recommend this "cordial as a sound and trustworthy preparation.

Literature.

THE POCKET PHARMACOPŒIA. (a)

This book, the work of an experienced chemist, assisted by a highly qualified physician, is an epitome of the

(a) "The Pocket Pharmacoporia, including the Therapeutical Action of the Drugs, with the Natural Orders and Active Principles of those of Vegetable Origin." By Frederic Hudson-Cox. F.I.O., F.C.M., Member of the Pharmaceutical Society of Great Britain, and John Stokes, M.D., B.S., L.S.S.C. Durham, M.E.O.S. London: Baillierie, Tindall, and Cox. 20-21 King William Street, 8 Btrand. 1839. Pp. 206. Price 2s. 6d.

British Pharmacopæia for 1898, with the addition of a few brief notes on the general therapeutic action of the various remedies mentioned therein

In order to be really a "Pocket Pharmacopœia," it is obviously necessary that this information should be very brief and condensed, and this has been judiciously done by the authors.

The more essential "pharmacy" part of the work is given with much completeness, the solubility of the drugs, with purity tests, being clearly and fully put forward.

Thus this Pharmacopœia is made a trustworthy guide for the busy practitioner, and an excellent book for thecandidate preparing for examination.

It occurs to us that the introduction of some of the popular names of certain preparations might be advantageous. For example, Fowler's solution under liquor arsenicalis. Griffith's green mixture under mixtura ferri composita, and a few more.

In examination, it is not uncommon for a candidate to be asked the composition of the above when named'

to him by their colloquial and popular names

The appendices of weights and measures, and the description of certain pharmaceutical processes as designed by the "New Pharmacopœia," add to the value of thisvery servicable manual

YEAR-BOOK OF PHARMACY. (a)

This ever-welcome year-book gives the pith of all scientific papers read during the year that have a bearing on medicines and their preparations. The present volume fitly opens with a summary of Dewar's paper on the liquefaction of hydrogen, a result obtained by the combined influence of a temperature of 205 degs. C. and a pressure of 180 atmospheres. The result marks an epoch in the annals of chemistry, disposing as it does of the idea of permanent gases, an idea which dominated

the state of the state of the different effects of dilute and concentrated sulphuric acid on potassium cyanide are of great interest, both to

the theoretical and analytical chemist.

Aconitine, according to Messrs. Dunstan and Cash,. owes its toxicity to the presence of an acetyl radicle in the molecule, a highly important fact, for it is by such carefully conducted examinations of the active principles that the therapeutic properties of drugs can only beestimated.

Senecio Jacabosa comes in for notice, and Dr. W. E. Fothergill's paper is summarised; but we regret that no mention is made of Dr. William Murrell's paper on the subject, which appeared in our columns and attracted much attention at the time.

Notes and Formula" occupy close on fifty pages, and well repay the reading. We need only mention the statement on page 248 that strontium salicylate does not disturb the digestive organs, as the alkaline salicylates-too often do The papers read at the Conference are very unequal. Some of them, as Mr. Stanford's on "Thyroglandin" and "Alginoids," Mr. Druce's paper on "Irish Flora," Mr. Howard's on the "Basicity of Quinine," are really valuable. But we cannot say as much for all that appear in this section of the volume. It is no kindness to an author to prolong the existence of a weakly offspring-that cannot command admiration

and only gives rise to commiseration.

Taken altogether the Year-Book is one of our most valued and valuable annuals, very helpful to the physician and invaluable to the pharmaceutical chemist.

INDEX-CATALOGUE. (b)

WE have rec eived the third volume of the second series of the Index-Catalogue of the Library of the Surgeon-

(a) "Year-Book of Pharmacy," comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign journals from July 1st, 18t7, to June 80th, 1889, with the Transactions of the British Pharmaceutical Conference at the thirty-fifth Annual Meeting, held at Belfast, August, 1886. London: J. and A. Churchill. 1898.

(b) "Index-Catalogue of the Library of the Surgeon-General's Office, United States Army." Authors and Subjects. Second Series, Vol. III. C. Czygan. Washington: Government Printing Office, 1898.

General's office, United States, America. It contains 11,112 author-titles, representing 4,873 volumes, and 10,690 pamphlets. It also contains 10,636 subject-titles of separate books and pamphlets, and 34,314 titles of articles in periodicals.

The Index - Catalogue, of which the first volume appeared in 1880, contains, as far as published, 209,554 author-titles, 192,851 book-titles, and 597,535 titles of articles in periodicals. The new series alone contains 33,190 author-titles, 24,294 book-titles, and 86,423 titles

of articles in periodicals.

The word "chloroform" occupies twenty-two closely printed columns in the present volume, two columns less than it did in the second volume of the first series. Anæsthetics occupy twenty-eight and thirty-two columns

of the first and second series respectively.

So far as the second series has gone, a volume is given to each letter of the alphabet, an arrangement that

facilitates reference.

The present volume is much more than an index of books and papers; it is a most readable volume, giving, in the titles of many of the older volumes which the industry of the librarian and the generosity of the United States Government have secured, a vivid picture of medical science in the fifteenth, sixteenth, and seven-teenth centuries, and also of the system of quackery then rampant, and pursuing lines of mendacity which to the quacks of to-day are so familiar. Under the headings "Cases," "Controversy," "Corre-spondence," we get a sidelight on the social condition of the past that is highly interesting. It is a strange

commentary on life that of the disputants whose names occupy columns, the great majority have passed away; the subject of the controversy forgotten—even their very names have become so unknown as hardly to excite

a passing moment's interest to the reader.

We and the whole medical profession are indebted to the Surgeon-General of the United States of America and the enlightened liberality of his Government for

this great work the Index-Catalogue.

LAHMANN'S NATURAL HYGIENE. (a)

THE author in his preface says :—"Those who have not studied physiology and pathology will not be able to run through the book on a Sunday afternoon, but will have to study it." Whether those who have studied physio-

to study it." Whether those who have studied physiology and pathology could not make a better use of their Sunday afternoons is at least open to question.

The author contends the "dysæmia" is the principal origin of all predisposition to disease; the term "dysæmia" is variously defined, perhaps the fullest definition being "used to denote an abnormal proportion of the food-salts in the blood, and especially a deficiency of those salts which are absolutely necessary to maintain of those salts which are absolutely necessary to maintain us in good health." The author also maintains the limited vitality of the so-called inorganic constituents of the animal organism and their participation in the same metabolism that takes place in the tissues.

To get enough of the proper salts, two courses are recommended; first, vegetarianism, which is "proved" as follows: - Carnivorous animals have atrophied, inactive sweat-glands, whilst man and herbivorous animals ossess well-developed sweat-glands. There is no doubt, possess well-developed swest-gishus. Incide in dealer, therefore, that the herbivora must have preceded the carnivors in point of time, the carrion-feeders being the connecting link between them." It is refreshing to find a mind that can sketch out in a few words such a profound theory, and can introduce the non sequitur conclusion by "There is no doubt, therefore!" It is sad to think that the author may yet have to realise the caution of the bishop to the curate—"None of us are infallible, not even the youngest."

The author holds, as so many fin-de-siècle vegetarians do, that starchy foods should be very little used, green vegetables, green salads, juicy fruits, and the author's food-salts and sugar syrup being substituted; ordinary table salt should be severely left alone.

The results of the author's system are striking pains of childbirth are nearly abolished, as the infants of mothers so fed are so small that they easily glide into the world. It may also be expected that the ovariotomist will cease to trouble, and spectacles disappear from the Vaterland, for we read:—"The cause of gottre and ovarian cyst is a local "hydramia (watery condition of osmotic processes)" just as is the case with short sight. The only difference is that, owing to anatomical conditions the osmotic enlargements of the goitre cyst or of the ovarian cyst may increase to any extent, for neither the thyroid gland nor the ovary have any system to allow of the escape of superfluous fluid. The pathology

of this is not to be grasped in a Sunday afternoon!

Daily bathing of the body to some does not do any visible harm, but when the skin is constantly rubbed it is deprived of the natural oil which renders it soft, and which is of greater importance in helping it to perform its functions than the cleansing effects of the bath.

The following testimonial is rather amusing and shows how little some grateful natures are thankful for-

"Dear Doctor, I have read your highly praiseworthy work, "Dietetic dysæmia," and have accordingly changed my vegetarian mode of living. The effect has been remarkable. Since the beginning of December, when I remarkable. Since the beginning of December, when I commenced the new regime, my urine has shown a deposit of gravel every morning (i.e., uric acid, brought into solution owing to the greater abundance of soda in this food), and the same thing occurs to my wife."

A number of photographs of the author's children are introduced to illustrate the advantage of being brought up on their father's system. The only one of interest faces page 204, and if not "faked" is an apotheosis of the mashed strawberry and resuberry (nage 207) faeding of

mashed strawberry and raspberry (page 207) feeding of infants; it shows a four months old infant standing erect on its father's hand, the fingers of which grasp the feet. The mother does not occur in the picture, so her feelings can only be guessed. The want of an index prevents some other amusing points noticed in glancing over the book from being recaptured and related.

A considerable amount of ignorance of thysiology and pathology will assist the enjoyment of this book on Sundays and weekdays.

BROUARDEL AND GILBERT'S MEDICINE AND THERAPEUTICS. (a)

This bulky volume is the fifth of a very imposing and valuable series. It deals with diseases of the salivary glands, pancreas, liver, spleen, kidneys, and genitourinary tract. From a scientific point of view it is fully up to the standard of its predecessors for each chapter is a monograph written by one or more acknowledged authorities, giving the most recent and complete infor-mation on the subject. The chapter on diseases of the liver, by Drs. Gilbert, Fournier, Garnier, and Surmont is a monument of research and careful observation. No point is left untouched in the 450 pages allotted to this We note with satisfaction that due credit one subject is accorded to foreign investigators whose claims to recognition are too often subordinated to misguided patriotic zeal. Not less remarkable is the chapter on kidney disease by Dr. Chauffard whose researches in this direction have secured him a world-wide reputation. As in the preceding volumes semiology and general pathology have been accorded an amount of attention not usually allotted to them in works of the kind, and this fact gives a special value to the articles. The claims of general pathology to recognition are now generally conceded, for its study enables us to condition to and concerning the multitudinous array of co-ordinate and generalise the multitudinous array of facts and observations which must otherwise lie idle. General pathology indeed may be described as the philosophy of medicine whereby the physican is enabled to group his facts and to deduce therefrom the general laws which underlie all morbid manifestations. To those for whom the French language has no terrors it cannot but be of exceeding interest and benefit to study disease through French spectacles. French writers have for the most

⁽a) "Traite de Medecine et de Therapeutique." Edited by Professors Brouardel and Gilbert, Vol. V. Pp. 1,000. Price 12 frs. Paris: J. B. Baillière et fils. London: Baillière, Tindall and Cox.

⁽a) "Natural Hygiene; or, Healthy Blood the Essential Condition of Good Health and How to Attain It. A Treatise for Physicians and their Patients on the Predisposition to and Prevention of Disesse." By H. Lahmann, M.D. London: Swan, Sownenschein and Co., Limited. 1898. Pp. 253.

part a singularly lucid way of expressing their ideas, and although the fond must obviously be the same, the manner of regarding and discussing the subjects presents marked points of contrast. We realise that it is possible marked points of contrast. We reasise that it is possible to be comprehensive without being prolix. This series constitutes a medical library replete with information, etiological, clinical, pathological, and epidemiological. Criticism is disarmed by work of this calibre and we can only congratulate the editors and their collaborators on the success of their combined efforts in the production of such a magnificent work of reference.

Medical Acms.

The Remuneration of Vaccination Officers.

THE Vaccination Officer of one of the rural districts of Daventry Union has just resigned his post on the ground that his total income from this source for the last three months had been only 5s. 7d., out of which he had to pay postages and Superannuation Fund instal-ments. His total income for the preceding year had not exceeded 30s. The guardians accepted his resignation, and decided to advertise for a successor at the same remuneration. Don't they wish they may get him!

The London and Counties Medical Protection Society.

THE annual report of this society testifies to much useful work during the past year in the protection of members against false accusations, inspired by ignorance, malice, or simply with blackmailing intent. The cash deficit of the earlier years has been converted into a cash balance of nearly £900, and this, it is to be supposed, though it is not specifically intimated, corresponds to a steady increase in the number of members. While we cannot but regret that there should be more than one such society, it is evident that each of them finds a field of useful activity. It is a matter for sur-prise that so many practitioners still neglect to avail themselves of the facilities offered by these associations to protect themselves against certain contingencies. As the knowledge of the extreme value of membership becomes more generally recognised, no doubt they will all come into the fold, and when this is the case the organisations will command more respect and carry more weight with the general public.

The Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held on March 24th, at 429, Strand, London, W.C. There were present the chairman, Dr. de Havilland Hall, Dr. J. B. Ball. Mr. J. Brindley James, Mr. F. Swinford Edwards, Dr. J. W. Hunt, Dr. Francis J. Allan, and Dr. W. Knowsley Sibley. The Francis J. Allan, and Dr. W. Knowsley Sibley. The influenza epidemic is in full evidence in the records of the Society, and, indeed, about half the sickness claims which have been received this year have arisen from this cause. They are, however, almost without exception of short duration, and, so far, the influenza record of the Medical Sickness and Accident Society for 1899 compares favourably with that of other years. The Society's business is now being valued, and there is little doubt that when the members meet together in May next there will be found to be at their disposal a substantial amount of surplus. The business is valued on a very stringent basis, and, in addition to this, special reserves are made for those chronic sickness cases in which the members are entitled to draw from fifty to one hundred and fifty guineas a year till aged 65. Nevertheless, out of the £126,000 of reserves now possessed by the Society there will be found a margin, and the members may hope to receive a substantial cash bonus as in 1894. Prospectuses, &c., on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The Corporate and Medical Reform Association,

WE have received from the indefatigable secretaries of this Association a report of the proceedings at a meeting of the Executive Committee, which took place on the 4th inst., at which a number of resolutions were adopted, urging combined and individual protest against the practice of issuing partial diplomas to unqualified persons in special departments of medical practice, notably in midwifery and sight-testing. We have also been favoured with a copy of the memorial on this subject addressed to the General Medical Council, signatures to which are urgently solicited.

Vital Statistics.

The deaths registered last week in thirty-six great towns of United Kingdom corresponded to an annual rate of 23 1 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year.

Birkenhead 24, Birmingham 28, Blackburn 26, Bolton 23, Bradford 21, Brighton 21, Bristol 21, Burnley 24, 23, Bradford 21, Brighton 21, Briston 21, Bulling 22, Cardiff 13, Croydon 17, Derby 19, Dublin 31, Edinburgb 22, Glasgow 22, Gateshead 20, Halifax 26, Huddersfield 20, Hull 20, Leeds 22, Leicester 18, Liverpool 28, London 22, Manchester 31, Newcastle-on-Tyne 22, Norwich 23, Nottingham 22, Oldham 30, Plymouth 28, Portsmouth 21, Preston 21, Salford 22, Sheffield 25, Sunderland 28, Swansea 21, West Ham 17, Wolverhampton 19. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 23 in Bolton, and 24 in Manchester; from whooping-cough, 10 in Bristol, 13 in Hull, 16 in Plymouth, 23 in Birkenhead, and 28 in Burnley. In none of the large towns did the deatherate from scarlet fever, from "fever," or from diarrhees reach 10 per 1,000. The 71 deaths from diphtheria included 31 in London, 10 in Swanses, 4 in Sheffield, 3 in Birmingham, and 3 in Liverpool No death from small-pox was registered in any part of the United Kingdom.

Mortality in Foreign Cities.

THE following are the latest official returns, and represent the last weekly death rate per 1,000 of the several populations:-Madras 36, Paris 27, Brussels 26, Amsterdam 16, Rotterdam 20, The Hague 17, Copenhagen 18, Stockholm 21, Christiania 18, St. Petersburg 27, Moscow 26, Berlin 21, Hamburg 19, Dresden 17, Breslau 24, Munich 21, Vienna 24, Prague 29, Buda-Pesth 26, Trieste 80, Rome 19, Turin (10 days) 20, Venice 28, New York (including Brooklyn) 19, Philadelphia 21.

Royal College of Surgeons in Ireland.

THE following is the prize list for the winter session 1898-99. Descriptive Anatomy: Junior—Mr. J. Cockburn, first prize (£3) and medal; and Mr. R. G. Allen, second prize (£1) and certificate. Senior—Mr. A. Charles, first prize (£3) and medal; and Mr. T. A. Dillon, second prize (21) and certificate. Practical Anatomy: First prize (£1) and certificate. Fractical Anatomy: First year—Mr. R. G. Allen, first prize (£3) and medal; and Mr. R. W. Burkitt, second prize (£1) and certificate. Second year—Mr. A. Charles, first prize (£3) and medal; and Mr. C. W. Ewing, second prize (£1) and certificate. Third year—Mr. C. R. Boyce, first prize (£3) and medal; and Mr. J. F. Peart, second prize (£1) and certificate. and Mr. J. F. Feart, second prize (£1) and certificate. Practice of Medicine: Mr. J. P. Byrne, first prize (£3) and medal; and Mr. T. J. Tallon, second prize (£1) and certificate. Surgery: Mr. J. S. P. Stewart, first prize (£3) and medal; and Mr. J. P. Byrne and Mr. W. R. Meredith (equal), second prize (£1) and certificate. Midwifery: Mrs. H. L. Hennessy, first prize (£3) and medal; and Mr. J. S. P. Stewart, second prize (£1) and certificate. Physical Research (£2) and Stewart, second prize (£1) and second prize (£1). certificate. Physiology: Miss M. J. Shire, first prize (23) certificate. Physiology: Miss M. J. Shire, first prize (£3) and medal; and Mr. A. Charles, second prize (£1) and cortificate. Chemistry: Mr. T. Keogh, first prize (£3) and medal; and Mr. G. G. Tabuteau, second prize (£1) and certificate. Pathology: Mr. J. F. Peart, first prize (£3) and medal; and Mr. H. Grabb, second prize (£1) and certificate. Physics: Mr. W. Ormsby, first prize (£3) and medal; and Mr. A. Ellenbogen, second prize (£1) and certificate. (£1) and certificate.

University of Glasgow.

THE following have passed the first professional examination for the Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B) in the subjects indicated (B., botany; Z., zoology; P., physics; C., chemistry):-

Boclet, Charing Cross Hosp.; John A. Drake, King's Coll., London; John P. Ellerington and Harold R. FitzNettle, University Coll., London.

Victoria University.

At the degree ceremony, held March 29th, the following candidates were presented, and received their

degrees:—

Bachelor of Medicine and of Surgery.—Second-class honours:
John Craig, Wilfrid Henry Richardson, and Oswald Humpson
Woodcock, Owens College: John White Aldred, Owens College:
Thomas Taylor Bark and John Turner Grierson, University College;
Thomas Wheeler Hart and John Edvidge Healey, Owens College;
William Saville Henderson and John Edward Whitley Mc Call,
University College; Thomas O'Neill, Owens College; John Arthur
Reed, Yorkshire College; and Graham Renshaw, Owens College.

Aotices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are par--ticularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

FORM C OF NEW VACCINATION ACT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,-I wish to draw the attention of the profession to Form C of Sir.—I wish to draw the attention of the profession to Form C of the vaccination paper given to parents, &c., at the registration of birth. The Local Government Board refuse private practitioners to fill it up. This is unjust. Surely a private practitioner is as capable of diagnosing "condition of house," and to have a knowledge of disease being rife in the neighbourhood as the Public Vaccinator is. It seems preposterous that if I have a private patient in an unfaanitary dwelling I must wait for the Public Vaccinator to grant postponement. If a public official is needed it surely should be the M.O.H. Trusting that your powerful paper will consider this subject worthy of ventilating and taking action in, probably best by bringing out a petition for signature and forwarding same in due course to the Local Government Board.

I am, Sir, yours truly,

R. F. Tomlin, M.B.C.S., &c.

Wood Green, N.

J. WARD.—Your postcard is illegible.

DR. C. DUMAS.—It is asserted by Dr. Phelps, of New York, that alcohol is a safe and sure specific against the escharotic action of pure carbolic acid. He suggests, moreover, that if, immediately after the administration of the poison, alcohol were given the poisonous effect of the acid would be neutralised. We have not, however, so far met with any confirmation of these statements.

THE PROFESSION IN BERLIN.

BERLIN and its suburbs are the happy hunting ground of some 2,233 doctors, being 37 in excess of the number for 1897. In 1825 there were only 191. The proportion to the population has rison from 1 per 1,183 inhabitants in 1825, 1 to 1,191 in 1837 to 1 per 754 in 1898. The total number of medical practitioners in the German Empire is put at 25,757, but Prussia alone claims 15,951 of these. Berlin alone maintains more doctors than the whole of Bavaria.

R. P. S.—We regret the delay which has been due to the difficulty of finding room for the articles. We hope, however, to be in a position to fulfil our promise in the near future.

Msssss. D. And B.—We have the matter in hand, and the result of our inquiry will be made public without unnecessary delay.

of our inquiry will be made public without unnecessary delay.

"CAN THE ETHIOPIAN CHANGE HIS SKIN?"

This Scriptural query is said to be attracting a good deal of attention in Vienna medical circles just now, by reason of its alleged elucidation in that city lately. The case is reported of a negro named Lacho, who was brought from the Soudan by an Austrian traveller, to whom he acted as valet. Seized with a nervous disease, Lacho was treated by a celebrated neuropathist by electricity, with the result that in four months he was cured of the disease, but had quite lost his natural colour. He is now said to be as white as a normal European, and, with his bushy hair and negroid features, to present a very remarkable appearance. We may be pardoned for not placing implicit reliance on the many strange cases reported; meanwhile we have asked our Vienna correspondent to kindly investigate and report should there be anything worth reporting.

Meetings of the Societies and Tectures.

WEDNESDAY, APRIL 12TH.

DERMATOLOGICAL SOCIETY OF LORDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Clinical Cases. Hunterlan Society.—8.30 p.m. Clinical evening. Cases will be shown by Dr. F. J. Smith, Dr. D. Boss, Dr. Herman, and other Fellows

Fellows.

THE SANITARY INSTITUTE (Parkes Museum, Margaret Street, W.).

8 p.m. Discussion on Practical Hygiene Teaching in Elementary Schools (opened by Miss Alice Ravenhill).

NORTHERN AND MIDLAND DIVISION OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION (County Asylum, Hatton, Warwick).—4 p.m. Spring Meeting. Discussion on the Nursing Staff in Public Asylums (opened by Dr. Macphail). Paper:—Dr. Wilcox: Some Cases of Insanity treated by various Animal Extracts.

THURSDAY, APRIL 13TH.

BOTAL INSTITUTION OF GREAT BRITAIN .- 3 p.m. Prof. Dewar:

The Atmosphere.

British Gynecological Society (20 Hanover Square, W.).—
8.30 p.m. Discussion on the Abdominal Causes of Death after Cæliotomy (introduced by Dr. W. J. Smyly, of Dublin).

FRIDAY, APRIL 14TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.). - 8 p.m. Council Meeting. 8.30 p.m. Ordinary

dish Square, W.). - 8 p.m. Council Mooding.

Meeting.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.). --8.30 p.m.

Papers: -Mr. W. G. Spencer: Wound of a large superficial Inguinal
Artery in which the Blood was flowing from the Trunk to the
Thigh. -Dr. Rolleston and Dr. C. Ogle: Syphilitic Stenosis of the
Bronchi. -Mr. C. Lucas: Two Cases of Ununited Fracture of the
Humerus caused by the Interposition of the Muscular Spiral Nerve
between the Fragments, -Dr. S. West: The Skin Affections in

ROTAL ACADEMY OF MEDICINE IN IRELAND.—Medical Section.— Papers:—(1) Dr. Coleman: Notes on a Case of Addison's Disease.—(2) Dr. Parsons: Cases of Pyloric Obstruction.— (3) Dr. R. H. Woods: Chronic Pharyngitis.—(4) Dr. MacDowel

Cosgrave: A Case of Poisoning by Primula Obconica.—(5) Dr. Lumsden: Notes on a Case of Diabetes Insipidus.—(6) Dr. Littledale: Clinical Investigations on Widal's Reaction as a Diagnostic in Typhoid Fever.—(7) Dr. Finny: Tachycardis, ending fatally by Thrombosis of both Femoral Arteries.—(8) Dr. Conolly Norman: Senile Dementia.—(9) Dr. O'Carroll: The Pulmonary Second Sound.

Bacancies.

on Union.— Resident Assistant Medical Officer at the Workhouse, Gravelly Hill, near Birmingham. Salary £100 per annum, with furnished apartments, rations, washing, &c. Apply to the Clerk to the Guardians. Aston Union.-

Births.

BARKER.—On April 6th, at 57, Warrington Crescent, London, W., the wife of Francis J. Barker, of a daughter.

Hamer.—On April 7th, at 22, Walpole Road, Twickenham, the wife of W. H. Hamer, M.D., of a Son.

HOWSE.—On April 7th, at 59, Brook Street, Grosvenor Square, London, W., the wife of H. G. Howse, M.S., of a son.

Krohn.—On April 4th, at Funchal, Madeira, the wife of R. E. S.

Krohn, M. D. Lond., of a son.

SKIENER.—On April 7th, at Bank House, Rye, the wife of Ernest W. Skinner, M.D., of a daughter.

Marriages.

BURNS—BAINS.—On April 8th, at Christ Charch, Emerydown, Hants, Theodore G. A. Burns, M. A. Oxon, M. R. C. S., of Dublin, to Bosamund, daughter of E. Talbot Bains, of Emerydown.

CHAMBERS—WOOD—On April 8th, at St. Mary Abbot's Church, Kensington, Wm. Francis Chambers, L.R.C.P., M.R.C.S., of Folkestone, to Edith, daughter of the late Prof. John Wood, F. R.C.S., f. E.S., of King's College Hospital.

MENZIES—GREEN.—On April 6th, at the Parish Church, Watford, William Francis Menzies, M.D., B.Sc., M.R.C.P., Superintendent of the Staffordshire County Asylam, Cheddleton, to Jessie (Daisy), second daughter of George Green, of Watford.

WISE—HUNTER.—On April 5th, at St. Margaret's Church, Plumstead, Harry Mortimer Wise, M.B., to Flora, younger daughter of G. R. Huuter, of the War Office, and of Plumstead,

Beaths.

Bannes.—On April 5th, at Perth, West Australia, John S. Barnes, B.A., M.D., aged 31, son of John M. Barnes, of Morningthorpe,

B.A., M.D., aged 31, son of John M. Barnes, of Morningthorpe, Norfolk.

Duncan.—On April 5th, at 8, Henrietta Street, Covent Garden, London, James Andrew Duncan, M.B.Lond., in his 80th year.

GIBBINGS.—On April 9th. at his residence, Dalston, London, N.E., Alfred Thos. Gibbings, M.D., aged 50.

HAWKINS.—On March 31st, at 3, Northernhay Place, Exeter, Thomas Hawkins, M.R.C.S., aged 68.

SQUIRE.—On April 2nd, at Danescombe, Ealing Common, William Squire, M.D., F.R.C.P., aged 73 years.

TOMKYNS.—On March 24th, at Green Bank, West Hill, St. Leonards, William Fancourt Tomkyns, M.R.C.S., aged 74.

A few Facts in favour of Scott's Emulsion.

Patients readily take and retain Scott's Emulsion when their stomachs and palates rebel against the plain cod-liver oil. A minute and uniform division of the oil is unquestionably an advantage, both in digestion and absorption. And in Scott's Emulsion this division is MAINTAINED INDEFINITELY, and the oil REMAINS FREE FROM RANCIDITY.

Glycerine is an important factor in Scott's Emulsion also, and should not be lost sight of. In the digestion of fat Nature makes glycerine; makes it for a purpose and uses it, thus showing the need of it. We add glycerine especially because it prevents fermentation, because it sweetens without aggravating uricacidæmia or glycosuria as sugar does, and because it assists absorption and aids nutrition. We owe much to the glycerine.

To the Hypophosphites of Lime and Soda we look for a necessary constituent of brain, nerve, and bone structure.

Is not the above combination better than plain cod-liver oil? And is it not a further advantage that the physician can absolutely rely upon Scott's Emulsion as being a PERMANENT EMULSION, FREE FROM RANCIDITY?

SCOTT & BOWNE, LTD., MANUFACTURING CHEMISTS, LONDON, E.C.

MELBOURNE, 1888.

BENGER'S

GOLD MEDAL AWARDED

Health Exhibition, London.

FOR INFANTS, INVALIDS, FOOD. AND THE AGED.

This delicious highly nutritive and most easily digested Food is specially prepared for Infants, and for those whose digestive powers have been weakened by illness or age.

The following letter addressed to F. B. BENGER & CO., Ltd., is published by special permission of the Russian Court.

"Balmoral Castle.

"Scotland, 25th Sept., 1896.

"Sirs,-Please forward to Balmoral Castle one dozen 2/6 Tins of BENGER'S FOOD for H.I.M. THE EMPRESS OF RUSSIA, addressed to Miss Coster. have received the box ordered from Peterhoff.

"Yours truly, F. COSTER."

The Lancet describes it as "Mr. Benger's admirable preparation."

THE MEDICAL PRESS says :-- "Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick."

The British Medical Journal says: -- "Benger's Food has by its excellence established a reputation of its own."

The Illustrated Medical News says: - "Infants do remarkably well on it. There is certainly a great future before it."

A Government Medical Officer writes :- "I began using your Food when my son was only a fortnight old, and now (five months) he is as fine a boy as you could wish to see."

From an eminent Surgeon: -- "After a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed."

A Lady writes:-" Really I consider that, humanly speaking, Benger's Food entirely saved baby's life. I had tried four other well-known Foods, but he could digest nothing until we began the Benger.' He is now rosy and fattening rapidly."

BENGER'S FOOD is sold in Tins at 1/6, 2/6, and 5/-, by Chemists, &c., everywhere.

Wholesale of all Wholesale Houses and Shippers, or of the Manufacturers,

F. B. BENGER & CO., Ltd., Otter Works, Manchester.

Telegraphic Address: "Benger's, Manchester."

Bynin

Perfection of Liquid Extract of Malt

Although Ciquid, BYNIN possesses the same diastasic power as the ordinary thick Extract.

BYNIN mixes readily with milk, helping Being Ciquid, complete digestion, and preventing the formation of large clots of casein.

As Liquid, BYNIN is far more pleasant to take, more easily mixed with other food, and more quickly BYNIN is far more pleasant to take, more assimilated than the thick Extract.

Bynin is a boon to Rursing Mothers, replacing Alcoholic drinks.

DIASTASIC ACTIVITY.—"We find that at a temperature of 100°F. one ounce will digest perfectly one pound of starch. This is a most satisfactory result, and, coupled with the fluidity and pleasant flavour, renders this preparation a most valuable one."—The Lancet.

Allen & Hanburys Ltd., Plough Court, London.

Johannis" NATURAL MINERAL WATER. LITHIATED.

Contains one grain of added Lithium Bicarbonate to each small bottle.

So much importance is attached to the action of Lithium Salts as solvents and eliminants of uric acid, in the numerous maladies referable to the uric acid diathesis, that it is of the greatest consequence the Lithium Waters in use should contain a definite and suitable quantity of a Salt of Lithium, and that this should be authoritatively guaranteed.

The Johannis Springs Company, acting under eminent medical direction, have undertaken to supply precisely the kind of Lithium Water needed for continued consumption as a table water. The amount of Lithium is constant, and the quantity, while adequate to produce the best effects of this valuable uric acid solvent on the organism, is strictly limited to such a dose as cannot possibly cause any cardiac debility, or increase it where it exists.

They have taken the natural mineral water of the **Johannis** Springs—containing as it does, in admirable proportions, Sodium Bicarbonate, small quantities of Sodium Chloride, as well as other valuable constituents, impregnated also, as it is, with its own absolutely natural and pure Carbonic Acid Gas—and to this water they have added a definite and constant quantity of Lithium Bicarbonate, so that each bottle shall contain one grain of this Salt of Lithium.

The Medical Profession, by prescribing for those suffering from or apprehensive of uric acid maladies, say, 2 to 5 bottles of Lithiated Johannis water per day, will administer regularly from 2 to 5 grains of Lithium Bicarbonate, combined with the other alkaline constituents of this valuable natural water, and their patients will have the great advantage of drinking a perfectly pure natural mineral water containing just as much of this uric acid solvent as is needed, and no more; while the additional eliminative and purifying properties of the Natural Johannis Water greatly enhance its value for the gouty constitution.

Per Case, 100 Small Glass Bottles 35/-

The Coulstonian Lectures

PATHOLOGY OF THE THYROID GLAND.

Abstract of Lecture III, delivered before the Royal College of Physicians of London.

By GEORGE R. MURRAY, M.A., M.D.Camb., F.R.C.P., Heath Professor of Comparative Pathology in the University of Durham; Physician to the Royal Infirmary, Newcastle-upon-Tyne.

Owing to the special anatomical position and physiological properties of the thyroid gland itaffords unusual facilities for observing some of the unusual facilities for observing some of the phenomena of compensatory hypertrophy. It is now a well known fact, owing to the work of Horsley, Halsted, and Edmunds, that when a portion of the gland is removed the remainder undergoes compensatory changes, in virtue of which it is enabled to supply enough secretion to prevent the appearance The portion of the symptoms of athyroidism. removed at one time may be one-half or even three-quarters of the whole gland, and Halsted has shown in the dog that sucsessive portions, if removed on three or four separate occasions, may be excised until only one-eighth, or even one-sixteenth, of the original gland is left without symptoms of athyroidism being developed. Although these changes are accompanied by an increase in size, the hypertrophied remainder does not attain the size of the original gland, so that, weight for weight, it has to do more work than the original glandular tissues. Under these circumstances it is not so surprising that the structure of a piece of the gland which has undergone compensatory hypertrophy should differ somewhat from that of the normal gland. When sufficient hypertrophy has developed to supply as much secretion as is necessary, we do not find a simple hyperplasia of the original glandular tissue, but considerable change in the structure throughout. The alveoli, instead of being nearly circular, become irregular in outline. This change is due to the folding of the wall, which projects at different points into the lumen of the alveolus. In advanced hypertrophy the lumen may appear to be star-shaped, or it may be almost obliterated by neighbouring folds of epithelium coming into contact. The appearance in places may thus closely resemble that of a racemose gland. The epithelial cells themselves are also obtained. altered. They are considerably increased in size, the ordinary low cubical epithelial cells being converted into tall columnar cells. The result of these two changes is that in equal areas the secretory cells are greatly increased both in numbers and size in the hypertrophied, as compared with the normal, gland. The colloid lying in the gland is diminished in amount, and appears to be more watery in consistence than normal. This change in consistence cannot, however, be accompanied by any deficiency in the active ingredients of the secretion, as it is able to prevent the onset of any symptoms of athyroidism. The appearances just described are evidently those of glandular tissue working at high pressure, and just able

to supply the necessary amount of secretion without storing any in reserve in the alveoli as is usual in the normal gland.

In illustration of these changes he referred to an experiment in which the whole of the left lobe and the greater part of the right was removed from a After the operation there was slight hebetude and harshness of the voice. No other symptoms developed, although the animal was kept under observation for fourteen months, and then was killed as it had contracted general tuberculosis. glandular tissue which had developed from the small portion of the right lobe left at the operation was found weighing 0.42 gram., showed the changes in structure which had taken place. The folding of the critical and an arrival and arrival arrival and arrival arrival arrival and arrival arriv the epithelium giving a larger secretory surface is clearly seen, and in some of the smaller alreoli near the centre the consequent irregular shape of the lumen is evident. The epithelial cells had become columnar in type, while the colloid was scanty, and seemed to be of watery consistence.

The remarkable results shown by Dr. Rose Bradford to follow the excision of a portion of the kidney, described by him in his Goulstonian Lectures last year, raise the question as to whether these changes in the structure of the thyroid are due entirely to the want of that body acting as a stimulus to the compensatory growth of the gland, or whether they are in any way due to some other local or general effect of the operation itself. If the compensating growth of the one lobe takes place simply in response to a call for more secretion to make good the loss of the other lobe, no hypertrophy should take place if this want is fully supplied from other sources. This point may be supplied from other sources. This point may be tested by removing one lobe of the gland and giving thyroid secretion continuously for some time, and then removing the other lobe for examination. If no changes indicating compulsory hypertrophy are found in the second lobe, it goes far to show that the hypertrophy develops simply as the result of an insufficient amount of thyroid secretion being present in the blood.

Similar appearances were found by Halsted in the thyroid gland of several healthy dogs. The occasional occurrence of such changes in apparently healthy animals is at present difficult to explain. The interesting point in this case is that after the prolonged interval of sixteen weeks, during which the extract was given, the left lobe was found to be paler in colour, and weighed 0.25 gram. The microscopical structure was normal, and showed no signs of commencing compensatory hypertrophy. If this lobe was originally in the same condition as the right the treatment seems to have restored it to a normal condition, and if not it at any rate showed no signs of compensating hypertrophy. As far as they go these experiments tend to show that if the proper amount of secretion is supplied after removal of one lobe compensating changes do not take place in the other. In connection with this part of the subject he had

tried the effect of prolonged administration of thyroid extract upon the healthy thyroid gland. It is well known that parenchymatous goîtres often decrease in size when treated by thyroid extract. One explanation of this result is that a partial atrophy from

disuse is established when the full amount of secretion is supplied from an external source. Two experiments have been made to ascertain if any atrophic changes could be induced in the healthy thyroid gland by supplying secretion ready made as it were and so doing away with the normal stimulus to secretion. The thymus atrophies after the first year of life from disuse, and the thyroid does so itself in old age, possibly for the same reason.

In the treatment of goître it is advisable to begin with 10 minims of liquor thyroidei each night; in the course of a few days, if the pulse is not accelerated beyond 90 or 100, this dose may be given twice, and at the end of a week thrice daily. If well borne, the dose may be still further increased. The treatment should be continued for three or four weeks to give it a fair trial, and longer if the goître continues to decrease in size. In several cases in which the general enlargement of the gland has been sufficient to cause dyspnces by compressing the trachea, so that an operation had to be considered, the gland has been reduced to two-thirds, or even one-half, of its former size, and all the symptoms of pressure removed, and with them the necessity for an operation.

The beneficial effects of this treatment may be due to the iodine which is present in combination with a proteid in thyroid extract, for iodine has long been used with good results in the treatment of goitre. It has been seen that the healthy thyroid of the monkey showed some signs of diminution in size under the same treatment, and this suggests that the decrease in size in goitre may be due to part of the enlarged gland passing into a resting condition, and consequent diminution in size if there is not an actual disuse-atrophy as a result of the treatment.

Exophthalmic goître, with its many varying phrases, is a disease of great interest from several points of view. Its various clinical types, and the great difficulties in treatment it often presents, render a true solution of the problem of its pathology of the

greatest importance.

The circulatory and nervous systems have each in turn been considered to be at fault, and it is only recently that attention has been drawn to the important part which is played by the thyroid gland in the pathology of the disease. The central and sympathetic nervous systems have been carefully examined in a considerable number of cases; in some they have been found quite normal, in others various lesions have been described, but these have varied in different cases, and on the whole appear to be rather secondary than primary in origin. The lesions found in the thyroid gland are far more constant in character than any yet described in the nervous system, and it is the most obviously diseased organ to be found in a case of exophthalmic goître.

In nearly all cases of exophthalmic goitre there is a palpable enlargement of the thyroid gland. On looking through his casebooks he had found notes on 70 cases of exophthalmic goitre which he had seen during the last nine years in the North of England, where the disease is not uncommon. Of these 8 were men and 62 women. All the 8 men had enlargement of the thyroid; of the 62 women all except 3 had enlarged thyroid glands. Taking both sexes together, only 43 per cent. of these cases had no goitre. It has been shown by Maude that in some cases enlargement of the gland may be present at one time and not at another, so that even in these three cases, which were only seen a few times, there may have been some enlargement at some other time during the course of the disease which had escaped observation. In any case, in 95 per cent. of my cases, there was either enlargement of the gland at the time the case was seen, or there was a distinct history of enlargement at an earlier stage.

The enlargement of the thyroid gland in exophthalmic goitre is as a rule uniform. In cases of long duration it may be irregular in shape and consistence owing to the development of fibrosis leading to the formation of irregular strands and masses of hard fibrous tissue in some parts of the gland. The veins on the surface are large and their walls are thin. In well-developed cases the goître is very vascular, and the arteries are dilated and tortuous, indicating that there was a liberal supply of blood during life. On section the cut surface presents a uniform appearance; it is lighter in colour and exudes less colloid than a normal gland. The general appearance is that of a gland in a state of great secretory activity, and has been aptly compared by Greenfield to that of the mammary gland during lactation. The number of alveoli is not only increased by the total increase in size of the gland, but in equal areas more alveoli are seen than in the normal gland. In many places the lumen of the alveolus is irregular in outline owing to the folds of the alveolar wall covered with epithelium projecting into it, so that, even when the gland is but slightly enlarged, there is a marked increase in the amount of the secretory epithelium. The lumen of the alveolus is in consequence diminished in size, in some cases to a considerable extent. The actively secreting part of the gland is thus inreased at the expense of the storage room, which is so ample in the normal gland. The epithelium which lines the alveoli and covers these folds is changed in type, for the cells, instead of being flat or cubical, are tall and columnar. There is less secretion to be seen lying in the classification to be seen lying in the classification. tion to be seen lying in the alveoli than in health. This diminution in quantity is partly due to the decrease in the amount of storage room. In addition to this, however, the alveoli are only partially filled, an appearance which suggests that there is a more rapid removal of the secretion from the gland than in health. The colloid is also more watery in consistence, and it stains less deeply than normal. Eosin does not stain it at all, and Renant considers that it resembles feetal colloid more nearly than that found in the healthy adult.

It will be seen that the structure of the gland in exophthalmic goitre resembles that in compensatory hypertrophy in a remarkable manner. In both there is the increase in the secreting structures as shown by the plication of the alveolar wall, in both the epithelium is changed from a cubical into a columnar type, while the secretion stored in the alveoli is less in quantity and more watery in consistence. The changes in compensatory hypertrophy are known to afford an indication of increased activity, so that it is fair to infer that the changes found in exophthalmic goitre show that hypersecretion is going on. For other reasons the most rational explanation of the complex symptoms of this disease appears to be that they are due to an excessive formation and absorption of the secretion of the thyroid gland, which may or may not be altered in composition, and to the constant presence of this excess in the blood, and to its action upon the metabolism of the tissues generally, but more espe-

cially of the nerve centres in the medulla.

According to this view exophthalmic goitre is the opposite condition to myxedema, the former being the result of excess as the latter undoubtedly is of lack of thyroid secretion in the blood. This is supported by the strong contrast which is presented by the symptoms of the two diseases, a contrast which is nearly as marked as that between the small fibrous and atrophied gland of myxedema and the enlarged hypertrophied gland of exophthalmic goitre. Associated with the former there is increase of weight, stolidity, subnormal temperature, dryness of the skin due to diminution of cutaneous secretion, with increase of electrical resistance and slowing of the pulse, while with the latter we find emaciation, ner-

vousness, normal or raised temperature, moist skin due to increase of secretion, with diminished electrical resistance and acceleration of the pulse. One may conveniently express the relationship of myxodema to exophthalmic gottre in their various degree of severity in the following diagramatic manner. Taking 100 as representing the normal amount of thyroid secretion in health, then 75 per cent. is probably about the amount of secretion formed in those cases of early thyroidal fibrosis with slight myxœdema. half the glandular tissue is destroyed and only 50 per cent. of secretion is formed, the symptoms will be moderate. If 25 per cent. the symptoms will be well marked, and if none at all is found they will be severe. In the reverse way, in exophthalmic goître 125 per cent. of secretion would be present in a slight case, 150 per cent. in a moderate one, 175 per cent. in a well-marked one, and 200 per cent. in a severe case.

In myxedema these percentages are in probability approximately correct. In exophthalmic goitre, however, there are no means of ascertaining how much secretion is actually formed. It may amount to much more than double the normal quantity in a severe case, so that these percentages are purely relative, and must not be taken to indicate the actual amount

of secretion present in the blood.

Another interesting point in the relationship between the two diseases is the repeatedly observed fact that recovery from exophthalmic goitre may be followed by myxedema, while, as far as is known, exophthalmic goitre has never been observed to develop in a patient already suffering from myx-cedema. In some cases the symptoms of exophthalmic goître diminish as those of myxædema develop, in others there is an interval of good health between the disappearance of the exophthalmic goitre and the onset of the myxedema. In a case recorded by Baldwin exophthalmic goitre developed in 1887 and recovery took place the following year, Two years after, in 1890, myxedema developed, which three years later was successfully dealt with by the thyroid treatment. In a similar case recorded by Jeffroy and Achard, and quoted by Moebius, the exophthalmic goître existed for twenty-three years and then subsided, to be followed by myxedema. After death the nervous system was found to be quite normal, and the thyroid gland in an advanced stage of atrophy. It thus seems evident that the development of thyroid fibrosis in exophthalmic goître, by lessening the over activity of the gland, leads to a subsidence of the symptoms, which, if the fibrosis and atrophy progress far enough, are replaced by those of myxedema. While these changes are taking place in the gland, the symptoms may pass from those of severe exophthalmic goître through all the stages mentioned in the table to those of severe myxædema.

One or two cases have been recorded in which the symptoms of myxædema are said to have coexisted with those of exophthalmic goitre. The reasons for asserting the coexistence of the two diseases in these cases seem to be rather slender, and to be largely founded on the presence of an irregular brawny swelling together with the symptoms of exophthalmic exgoître. A firm subcutaneous swelling is sometimes met with in some parts of the body in exophthalmic goître, but it certainly was not myxœdematous. It is important to have such cases carefully reported, so that more information may be obtained on this point. The persistence for a time of a few symptoms of exophthalmic goître in a case of long duration which was passing into myxœdema is not unlikely, for the effects of the long continued action of an excess of secretion on the nerve centres in the medulla, may easily remain for a time even after the thyroid had begun to atrophy, just as the effects of the action of

lead or the toxins of diphtheria on the nervous system

persist long after they have ceased to act.

The physiological effects of thyroid secretion in large doses are of special interest in this connection. Exophthalmic goître, though rare in the lower animals, has been observed in the horse, the cow, and the dog, so that if the right cause is brought into operation there should be no great difficulty in producing the disease in one of these animals. As we are ignorant of the causes of the change in structure and activity of the thyroid gland in exophthalmic goître, attempts can only be made to reproduce the symptoms we believe to be secondary to the excessive activity of the thyroid. This can be done either by grafting an excess of thyroid gland tissue into an animal, or more certainly by feeding it with large quantities of thyroid secretion. or by injecting it beneath the skin. Ballet and Enriquez, by feeding dogs with the thyroid glands of sheep, produced distinctive symptoms in three out of six cases. These symptoms were elevation of temperature, tachycardia, tremors, conjunctivitis, emaciation, and in one animal quite distinct exophthalmos.

Still more important are the results which have been observed and follow large doses of thyroid extract in man. A condition of thyroidism seems to be more easily produced in those who have recovered from myxœdema than in those who have normal thyroid glands. It may develop rapidly if large doses are given, or more slowly if smaller, but still excessive doses are given for a long period. The earliest and most common symptom is increased frequency of the pulse. The patient complains of palpitation, and the heart beats violently 100, 120, or 130 times a minute. A fine tremor of the hands is often present, and the skin is flushed and moist. If the large doses are

continued for some time emaciation also takes place.
In addition to these symptoms, elevation of temperature, restlessness, loss of sleep, polyuria, albuminuria, glycosuria, partial paraplegia, sensation of heat, and diarrhea, all of which are occasional symptoms of exophthalmic goitre, have been recorded. In one remarkable case Béclère observed exophthalmos and rapid respiration in addition to other symptoms among those already mentioned in a woman who had suffered from myxædema, and had

taken 92 grams of thyroid gland in eleven days.

Some remarkable toxic symptoms have been observed in some cases by Horsley and Rodocanachi, Paul, and other surgeons, to follow partial removal of the enlarged thyroid gland. The most common symptoms which have been observed are fever, great frequency of the pulse (amounting to 150 or even 180 beats in the minute), rapid respiration, and great restlessness. In some of the cases the termination has been fatal at the end of a few days. Such symptoms have not been observed after a total thyroidectomy, so that they are not a result of the opera-tion itself. The symptoms have occurred in cases of exophthalmic or soft parenchymatous goftre after removal of one lobe of the enlarged gland, and especially when it had been so much handled or squeezed during the operation. In several cases a profuse flow of thyroid secretion has been observed to take place after the operation from the divided isthmus into the wound. The symptoms are similar to those in acute cases of exophthalmic goître, and in thyroidism artificially produced in the manner already described, and are evidently due to absorption from the wound of thyroid secretion poured out from the cut surface of the gland, or a large quantity of it being squeezed during the operation into lymphatics, and so into the blood stream.

This absorption of the secretion is a source of real danger in operations for goître, and especially in cases of exophthalmic goître. If, however, the gland be handled as little as possible during the operation,

the cut surface is sealed by the cautery, and a free exit is provided for any secretion which may find its way into the wound, such symptoms will in all probability but seldom arise.

It is now well known that thyroid extract has a bad effect on patients with exophthalmic goître. Under its influence the pulse becomes more frequent and the other symptoms are increased. In some instances where other treatment had been followed by a marked improvement the administration of thyroid extract had been followed by a relapse into the former condition. In short it should never be given in exophthalmic goître, as it is only adding fuel to the fire.

The results of surgical treatment of exophthalmic goître, undertaken with the object of reducing the amount of secreting tissue by removal of one lobe, or of inducing atrophy by ligature of some of the arteries which supply the gland, are of great interest. Unfortunately the operation itself, though sound in principle, is at present by no means free from risk. The steady improvement, however, which has resulted in many cases in which it has been successfully performed affords still further evidence that the symptoms of exophthalmic goître are due to the overactivity of the thyroid gland.

It is a fact of considerable interest that along with the enlargement of the thyroid gland in exophthalmic goître other ductless glands may be increased in size. The thymus gland is very often enlarged; in all the cases recently examined at St. Thomas's Hospital Dr. H. Mackenzie has found the thymus persistent and enlarged, the microscopical structure being normal. Exophthalmic goître and acromegaly resometimes found to occur together. He himself had recorded two examples of this and collected records of three others. In acromegaly the pituitary gland is enlarged, and the enlargement seems to be analogous to that of the thyroid in exophthalmic goitre, so that there is the remarkable fact that all these three ductless glands may be simultaneously enlarged. No explanation of this is forthcoming, but it suggests that possibly some common factor may be the cause of the enlargement. That some association exists between the thyroid and pituitary glands is further shown by the enlargement which takes place in the latter when the former is removed or disabled by disease.

These facts all indicate that in the treatment of exophthalmic goltre attention should be directed to the thyroid gland. Time will not allow the discussion of the question of operative treatment, but there can be little doubt that removal of part of the enlarged gland is a rational method of treatment, and when the risks of the operation are diminished it should be more frequently employed in severe cases in which medical treatment has failed to do good. Of medical treatment much has been written. Inunction of red iodide of mercury ointment over the goître and belladonna given in large doses internally, so as to check the hypersecretion of the gland, have proved most serviceable. If the palpitation is excessive, convallaria has proved more useful than any other member of the same group of drugs. If there is great nervousness the bromides have done good. In only one case have decidedly good effects followed taking thymus. In this case three tablets of dried thymus were taken each day for nine months, for the last six and a half of which the red iodide of mercury was used as well. As a result of this treatment the pulse-rate, which varied from 132 and 148, fell to 84, the thyroid gland, which had been considerably enlarged, returned to its normal size, the tremor became much less, and the exophthalmos was diminished.

NOTES ON THE PLAGUE. (a)
COLLATED

By SIR CHARLES A. GORDON, K.C.B., M.D., Surgeon-General (retired), Hon. Physician to Her Majesty the Queen.

(Concluded from page 317.)

In further considering evidence brought before the Committee on Plague, and otherwise published, the same mode of arrangement as that adopted in the former articles is observed in the remarks which follow, bringing the whole down to the end of March, 1899. As in the former articles so now particular items of evidence are recorded in the order in which they appear in papers quoted from, namely:—

1. DIAGNOSIS.

At Barisal the type of plague was purely pneumonic, and very virulent. In Calcutta deaths by it were registered under other names. Dr. Hossack had experience of a modified form of the disease at Poonah; he had seen mild cases of fever with enlarged glands, which he did not believe were of plague. So had Dr. Bannerjee. Although direct evidence was wanting that native doctors returned plague deaths as something else, suspicious deaths were so returned by friends of patients.

Surgeon-General Harvey was of opinion that the records of causes of deaths were incorrect; that a system of death certificates, though possible, would be unpopular; Dr. Ferras that there never had been plague cases in Calcutta, but simply cases of malignant fever. He had seen similar cases which were indistinguishable from plague except bacterio-

logically.

Dr. Hankin considered that, as a rule, plague was easily diagnosed by means of the microscope, but that in certain cases diagnosis was extremely difficult, revealing only a few isolated and faintly stained bacilli; in others microbes, degenerated in form, variable in size and shape. There was no doubt that in some no microbes were visible at the time of death, as proved by the German and Austrian Commissions.

Colonel Thomson looked upon the suggestion that mahamari and plague were identical as being a pure assumption. At Jawalpore, according to Dr. Elphick, of 116 cases of plague there were buboes in 81; no external buboes in 35. Of the former 22 recovered and 59 died; of the latter all but one died. Of the 35 cases 19 were of pneumonic plague, 1 of internal hæmorrhage and bubo, 15 believed to be of septicæmic type. He believed that the incubation period was about five days. In the Agra district Captain Grant reported that the early cases were pneumonic, and invariably fatal; afterwards they were bubonic, and then some recoveries took place. Captain James, of Lahore, had seen mild cases of pestis ambulans, principally at the end of the epidemic, and among boys.

and among boys.

Captain Wilkinson had not seen any pneumonic cases in the Punjab. Major Ross said the information given of cases was insufficient. Not more than 30 per cent, were reported. Major Skinner disagreed with Dr. Cobb and Dr. Simpson in their diagnosis of cases of fever with buboes in the Shropshire regiment. The cases in that regiment resembled malarial cachexy; the patients were ansmic, and had buboes; six deaths occurred. Some had acute intermittent or remittent fever, and developed buboes while under treatment. There was generally no fever until the bubo suppurated.

At Kurrachee the native doctors did not conceal cases, nor did they report the causes of deaths incorrectly.

⁽a) From Reports principally in the Times and Indian papers.

Colonel Maconachie, of Poonah, said the noticeable features of plague were the patient's staggering gait and whispering voice. There was no difference in the symptoms of Europeans and natives.

Dr. Mackenzie said that in Kurrachee malarial fever declined when the plague raged. When buboes were confined to the femoral region the chances of

recovery were favourable.

At Lahore, Muhamed Nawaz Shah said that there was a disease much like plague, which passed off of itself in children and youths of 20 or 22 with fever at the end of December and in January. nervous people were most liable to that disease.

2. Indemnity.

Mr. Griesbach gave evidence pointing to the trap and crystalline area as being specially adapted to the spread of plague. Bombay and the Deccan are situated on the trap formation. Epidemics cling to localities in a manner influenced by geological forma-

At Calcutta several cases of suspected plague curred sporadically. At Nasik and Malagon, occurred sporadically. endemic as well as imported plague was mentioned by Mr. Silcock. At Bombay, evidence went to show that the disease had been endemic for centuries. the district of Satara the majority of villages affected were situated on the banks of rivers.

3. LIABILITY.

Dr. Bose, of Calcutta, noticed that his patients were young or middle aged. He believed that old age was immune from plague. In Agra district Captain Grant found all his cases were among grain dealers (bunnyas) in the first epidemic of November, 1897; but in its recrudescence in January, 1898, plague was not confined to that class. At Kurrachee Mr. Kaka found that the disease had a tendency to persist in certain sects of the people. Dr. Niblock found that its incidence was the same in both sexes. At Lahore Dr. Clark was of opinion that all races were equally liable to it. At Daman the greatest mortality was among the Mahomedans. At Bombay, according to Professor Gajjar, attacks by plague were most frequent during night.

4. SEASON.

In the district of Barisal the first case of plague occurred on September 4th, 1898. In Calcutta, according to Dr. Bose, in the first week of April in that year; at Hurdwar, according to Colonel Thomson, it was discovered in April, 1897; it continued to prevail till June, when it ceased, but in that month spread to Kurnal, where it continued till the end of the year. According to Mr. Winter, however, the epidemic at Hurdwar continued till May, 1898. At Kurrachee the first case of plague occurred in December, 1896, the epidemic ceasing in July, 1897. A second epidemic appeared in March, 1898, and in January, 1899, was still prevailing. At Sukkur seasonal heat had no effect in reducing the disease, the temperature being 115 degs. F. in the shade.

According to the evidence of Mr. Sladen the epidemic at Kurrachee was on the decline from September, 1898. In the state of Palampore the first epidemic began in February, 1897; it continued till May of that year, then ceased; in the following August a second epidemic appeared. At Mandvi it prevailed from March till August, 1897. At Ahmedabad it occurred in October, 1896; at Umrath in September, 1898; Baroda in February, 1897, occurring as a second epidemic in October, and continuing till the following April. In Surat it occurred in December, 1896. At Belgaum it began in July and ceased in September. At Ahmedabad a second epidemic appeared in October, 1897, and continued till March, 1898, when it ceased.

5. PLAGUE BACILLUS.

Surgeon-General Harvey stated that the plague germ had sprung from a pre-existing germ. It would not flourish except in a suitable environment of dirt and poverty.

Dr. Cook at Calcutta had examined twenty cases of plague, and found the plague bacillus in nearly all. Colonel Adams, of Rijpootana, stated that the germs of plague were carried great distances in

persons' clothes.

Dr. Cobb and Dr. Simpson had declared that in the blood of cases of plague in the Shropshire regi-ment, bacilli were found. Major Skinner had Major Skinner had examined all the specimens and found no bacillus. Other evidence bearing upon this subject in relation to diagnosis is quoted under that heading.

6. How Communicated.

In Barisal, two aged women who were in constant attendance on patients in the same house, were not attacked. Many who left Calcutta were not ill while travelling, but fell ill the day after arrival (at Barisal). Dr. Rose said that plague was brought to Calcutta by six men from an infected district in Bombay, they carried the infection in their clothes and bundles. There was no specific instance of men coming from Bombay with the plague, but only suspicion. He traced the infection from street to street by human agency. He did not believe that grain or articles of food carried infection. Dr. Hossack was of opinion that it was impossible to trace the connection of infected cases. Colonel Fullerton said that there were three imported cases of plague among railway passengers, but no others in Baluchistan.

Captain White was of opinion that accidental inoculation by abrasion of the skin or mucous membrane was the exception rather than the rule. He doubted whether such abrasions were sufficient to account for the large number of femoral, inguinal, and axillary bubos which amounted to 75 per cent. of total cases. Colonel Adams believed that plague spread in a limited way by rats. Captain Grant, of Lahore, that cases treated in hospital seldom or never communicated the disease. Captain Wilkinson, that it was conveyed by human agency, there was no evidence that it was conveyed by rats or clothing; attendants in hospital were not attacked. Major Ross, that in Poonah it was transmitted by human beings, clothes, and rats. In the case of the Shrop-shire Regiment, Major Skinner considered that there was no infection.

At Kurrachee, Dr. Mackenzie was of opinion that infection entered by means of cargo, or by rats. The second epidemic at that place spread rapidly, owing, it was said, to evacuation of the houses causing the rats to scatter. Mr. Kaka was of opinion that rats spread the disease. Colonel Maconachie that Poona

was infected by railway passengers.

In the city of Ahmedabad, of the first three cases, one occurred in a person arriving from Bombay, two in residents employed in the goods yard. In one village of that district the infection was said to be wind borne. At Umrath, in September, 1898, that it was imported from other villages, the infection possibly conveyed by fleas. Persons employed in washing disinfecting houses with lime were attacked. Most of the cases spread by human agency. In Baroda and Nasik it was said to be conveyed by human agency. At Surat, to have been imported from Bombay. Human agency was thought necessary for importa-tion of the disease. Grain was not a factor in its dis-semination. At Daman, believed that it had been imported from Kurrachee by the crew of a native craft.

Lieutenant-Colonel Waters was of opinion that in Bombay the origin of plague was associated with the protracted storage of grain prevalent in India; that plague germs were mainly disseminated by the wind. Professor J. Gajar, of that city, attributed the disease to air germs, foul gases from decomposing animal matter in the soil. Dr. Kristina, that it was infected direct from Hong Kong by means of Chinese goods. Evidence next went to show that it had not been imported, but was indigenous, and had been so for centuries. At Poonah contagion was said to be rare except in the pneumonic form of the disease.

7. WATER, MILK, &C.

No reference to either vehicle of zymotic affection occurs in the evidence available for the purpose of the present notes

8. In Relation to Animals.

At Barisal, Dr. Justice attributed epidemic plague to the presence of dead rats. In Calcutta a heavy mortality of rats was noticed in March and April, plague having appeared in the latter month, but, according to Dr. Bose, there was no evidence that those animals had died of plague. Captain Bingley believed that the epidemic was due to rats from the river landing places. At Poonah, Dr. Hossack had a suspicion that rats diffused the plague, although at the commencement of the epidemic there no rats were seen. At Hurdwar, while plague prevailed, there was a concurrent mortality of monkeys. In the Agra district, plague was by the villagers called "the rats." No rats were met with however. At the beginning of the second epidemic at Kurrachee an extraordinary number of dead rats and others dying were found in the Jeryia Bazaar. At Lahore, according to Captain Wilkinson, the victims in one village were rats, while no human being was attacked. In his opinion, there was no positive proof that rats communicated the disease to people. At Vinsol, dead rats were seen a fortnight prior to the first case of the plague; during the epidemic fleas swarmed. In Broach, Mr Pettigara had known squirrels and cats to die of plague; he cited a case of infection from a cat. At Bombay, Dr. Mahomed suggested that plague might have been brought from Hong Kong by ships carrying fomites or dead rats. At Ahmednuggur there was no great mortality among the rats.

9. Anti-Plague Serum.

Surgeon-General Harvey was of opinion that it would be advisable to standardise Haffkine's fluid. Of that fluid Dr. Cook examined twenty five bottles, in seven of which he found impurities, including sarcina and mesentericus. He did not think that organisms which might be mistaken for those of plague could live in Haffkine's fluid, but of six bottles sent from Hyderabad, one contained impurity. Captain Johnstone tested seven different "brews" of Haffkine's serum, and found all contaminated, some with pathogenic organisms. At Surat that serum was considered valuable, apart from its prophylactic properties, because it gave the people a sense of security. At Bombay, Dr. Mayrs described the treatment by means of Lustig's curative serum; in two cases of plague three injections resulted in recovery of the patients.

Dr. Haffkine stated that though this prophylactic was generally sterile, it was impossible to avoid occasional impurities, but the danger therefrom was

Dr. Fraser and his colleagues have decided to put under special observation a certain number of cases as they arrive in hospital, to treat one half of them with Professor Lustig's serum, and give the other half such assistance as the hospital affords without the serum. They thus hope to arrive at a just and reliable estimate of the efficacy of the serum in plague cases, as compared with the usual hospital treatment.

Our knowledge of the nature of the material of refused to be inoculated.

serums is so limited, and the conditions of their preparations so manifold, varying, and uncontrollable that it is well nigh impossible to manufacture them twice with identical properties. In addition, the experience gained by their use upon the lower animals is not always verified in man. The action of a body of bacterial origin is confined to one disease, and influenced by a variety of conditions including predisposition and resistance. Hence, the oft repeated experience that cases looked upon as favourable for bacterio-therapy have frequently had a fatal termination, the Plague Commission has, therefore, proposed to mix and average the serums obtained from different horses at the Parel laboratory-for everything is not yet know of the possibilities of the Lustig serum.

10. Inoculation.

At Calcutta Dr. Bose was converted to the principle of inoculation because he was unable to resist the evidence of facts. Dr. Hossack mentioned three cases of plague among Europeans, of whom one, a nurse, had not been inoculated. Dr. Cook made cultures from heart's blood, lung stuff, sputum, and other things. He inoculated animals from his cultures, and killed them with unmistakable plague. Captain Clark said that in the Hushiarpore district 1,467 inoculations were performed; some of those inoculated took the plague, but in other villages there were cases of that disease. Captain Jenny at Kurrachee used Dr. Simon's curative serum with a slightly favourable result, Colonel Maconachie was inoculated with Haffkine's prophylactic, the dose being three centimetres. On the following morning he had slight fever, but the temperature did not exceed 103° F., no vomiting or diarrhœa. He had never seen dangerous symptoms resulting from inoculation. Dr. Nazareth inoculated forty-seven patients with Professor Roux's serum, the dose forty cubic centimetres each; of these twenty-five recovered. The effect of the inoculation was generally marked. It almost invariably failed in pneumonic cases, where the glands were suppurated.

The treatment was supplemented by stimulants.
At Lahore Captain Clark said that inoculation gave very beneficial results. Many hundreds were inoculated, and there were no cases among them, whilst there were several among the uninoculated. notable results were in connection with the disinfecting gangs which were partially inoculated. Among the smaller number of the uninoculated there were many cases, In other instances, from among nine men inoculated there was no case, whilst from fifty men not inoculated there was one case. Among sixty inoculated elsewhere there was no case; among twenty not inoculated, but one case. At Baroda, of 513 persons inoculated there were three deaths; of 437 uninoculated, nine deaths. At Kylee, of 1.159 inoculated lated, nine deaths; of 2,162 uninoculated, 110 deaths In some cases evil results followed inoculation, but it was doubtful whether they were due to that operation. Among the patients who recovered, the disease was milder in the cases of the inoculated than the uninoculated, At Surat 121 persons were inoculated, none of whom became attacked by plague; there the usual measures were adopted. At Nasik and Bombay Mr. Stewart had no experience of inoculation, but he strongly advorated evacuation and disinfection. In Mazagon and Tarwadi districts, of 7,000 persons inoculated there was only one death from plague. Mazagon was totally evacuated, and 12,000 persons removed into camp.

At Poonah Lieutenant-colonel Fawcett reported that inoculation was but a makeshift; useful perhaps, in times of trouble, but cannot take its place among the great sanitary laws. At Satara people

M. Haffkine considered that the general low mortality among inoculated people was due to the fact that the inoculation of pathogenic microbes influenced the course of diseases by other infections

as well as plague.

Elsewhere the remark occurs that the existing methods of administering both the preventive and curative serums has involved an enormous amount of waste, and failed to do the amount of good they might otherwise bave effected. The faith of the public in the Lustig serum depends upon its judicious employment in competent hands, and at present in spite of its success in many grave cases, it has not gained general confidence.

(To be continued.)

Lecture on RACHITIC DEFORMITIES.

DELIVERED AT THE CITY ORTHOPÆDIC HOSPITAL, By CHISHOLM WILLIAMS, F.R.C.S., Ed., &c.,

Assistant Surgeon, City Orthopædic Hospital, E.C.

GENTLEMEN,—Before proceeding to the consideration of "Rachitic Deformities," it will be well for us to briefly consider the disease itself. Rickets is a general disease, affecting the nutrition of the whole body in infancy and childhood. It is characterised by an arrest of natural growth and development, with a perverted and delayed calcification of the whole osseous system and enlargement of the glandular, more especially such abdominal glands as the

liver, spleen, and lymphatics.

Etiology.—The disease is most commonly developed about the end of the first year. It is said to be somewhat rare before the sixth month (I have recorded eleven cases, of well-marked rickets, between the third and sixth month). It may occur at any later age up to about eight years, and a few cases have been reported at 12 or 14 years, at these later years it is termed "recrudescence of rickets," and it is very difficult to say if the disease has only just been developed, or whether it has remained dormant from early infancy. This disease is never congenital, and the term "feetal rickets" is misleading, as it refers not to true rickets, but to early cases of sporadic cretinism. The most frequent causes are undoubtedly improper food and feeding, both as regards quality and quantity Starch and starchy foods are powerful agents in its development. Regard. ing "patent foods," according to a series of cases reported by Dr. Baxter, as many as 92 per cent. of his patients had used patent food, but this I think comewhat high. I have only been able to obtain a history of this kind of feeding, wholly or pertially, in 66 per cent. Bad hygienic surroundings, as dampness, want of fresh air and sunlight, and deficient accommodation, debility on the part of the mother, whether caused by disease, excessive childbearing or over-suckling.

Pathology.—In the bones any natural curve is exaggerated, but later secondary curves may develop. The epiphyseal junctions are enlarged, owing to their bulging from pressure between the epiphysis on the one hand, and the diaphysis on the other, the intermediate cartilage very slowly and imperfectly calcifying. In a rachitic bone, on section, one sees that the epiphyseal cartilage is much in excess of normal, and although calcification is progressing it is irregular and incomplete, and the line of ossification, irregular and jagged, also islands of calcareous material are found in the enlarged epiphyseal cartilages, and portions of unaltered cartilage are to be seen in the most recently newly-formed bone. Microscopically, there is great irregularity in the rows of

cartilage cells and much imperfectly formed bone. Under the periosteum similar changes take place. instead of new normal bone being formed, there is layer on layer of soft animal matter, very imperfectly ossified. These layers have been termed "osteoid Deformities occur most frequently in the following order:—Extremities, thorax, spine (kyphosis, scoliosis, and lordosis), skull, pelvis. Parchment-like crackling on pressure on the bones of the vault. more especially in the occipital region, has been named by Elsässer "craniotabes," and is said to be observed also in congenital syphilis. The fontanelles remain unclosed long after the second year. The urine contains more phosphates, less urea and uric acid, than normal.

Prognosis - Depends entirely upon the duration of the disease, if short, easily arrested, and pulmonary complications warded off, it is favourable. Aftergrowth is never perfect except in the mildest of cases. Regarding bony deformities, the younger the case the easier the rectification, the more extreme cases are due to imperfect general treatment at an early age, and allowing the bones to take care of themselves, which may cause a dense, buttress-like mass to form on the concavity of the bones, which will perpetuate the deformity and require the more severe measures for their relief.

Complications.-Rachitic children are extremely sensitive to cold, and are especially prone to catarrh, both pulmonary and intestinal broncho-pneumonia being the most common cause of death in this disease. Laryngismus stridulus is particularly frequent. Tetanic convulsions may occur in a few cases.

Symptoms. The earliest noted by the parent are usually vomiting and diarrhoea, and bending of limbs. but long before the latter have developed we find sweating of the forehead, mostly at night, kicking off bed-clothes, and general restlessness, the hair on occipital region being often worn off; excessive and unnatural tenderness on handling, with general lassitude. The abdomen is enlarged over the whole of its area, due to flatulence from the gastric and intestinal catarrh, and this increase in size may be partly due to enlargement of both liver and spleen; most frequently there is diarrhoa, but in a few cases there may be constipation, or alternating diarrhœa and constipation, the motions being pale and of putty-like consistence and extremely offen-sive. Urine is often increased in quantity, and loaded with phosphates. The head is unduly large and the forehead square, with prominent frontal eminences, the teeth late in appearing, deficient in enamel, and more or less rotten, the chest yielding to atmospheric pressure, presents two grooves, running downwards and outwards, just inside the nipple lines. and another groove transversely across lower part of thorax, the liver keeping the lower ribs and cartilages from falling inwards, thus producing the deformity known as "pigeon breast." The clavicles present a well marked bow near their inner extremities. At the junction of ribs and cartilages the swollen epiphyses can be felt and often seen, pro-ducing the so-called "Ricketty Rosary." The long bones give way in the direction of their normal curves, other curves being produced later, giving rise to knock-knees, bow-legs, and other deformities. The swelling of the epiphyses and the thickening of the cranial sutures are found in the vast majority of cases. The spine in the younger patients presents a long even convex curve, from the cervical to the sacral regions, which disappears almost entirely on raising the child up by the axillæ. Scoliosis is not very common, and lordosis is somewhat rare in early years. The pelvis may be affected, either being tri-angular or hour-glass shaped. Most rachitic patients are of stunted growth with weak and flabby muscles, in general condition they may be either very thin, or

very fat, but when the latter, the fat has not the usual firmness of health. Muscular action can have but little to do in producing deformity, the chief causes being pressure and force of gravity.

TREATMENT.

Resolves itself into five component parts—the hygienic, dietetic, medicinal, mechanical, and opera-

Hygienic.—Advice should be given as to general hygiene, and the child should at all times be thoroughly and warmly clad, abundance of fresh or freshly-prepared food, fresh air, with particular stress laid on the avoidance of chills and cold. Daily baths, tepid in winter to nearly cold in summer, night and morning, preferably sea-water, or its excellent substitute, sea-salt water, being used, to be followed by plenty of good friction, or, if possible, systematic massage, this seems to be of greatest value in the "tenderness" stage, causing it to disappear very quickly. In very young and severe cases, particularly in females, the child should be kept lying down, but never long in the same position, so that the pressure on the pelvis may be varied, this will tend to prevent any severe deformity.

Diet.—Under seven months, mother's milk, supplemented, or substituted if necessary, by fresh cow's milk diluted with at least one-third boiled water, and slightly sweetened with white sugar, with the addition of a teaspoonful of lime water to each bottle, afterwards a little rusks, yolk of egg, broth, or a small quantity of beef tea or gravy daily. Later the milk may be thickened with well-baked wheaten flour. After twelve months strong beef-tea may be added, and meat juice or pounded warm mutton or beef, a few teaspoonfuls daily. Freshly gathered stewed stone fruit is of great benefit in the later

feeding of a case, and in older children. Drugs.—As a preliminary step, and almost as a matter of routine, one or more teaspoonfuls of castor oil or rhubarb and soda should be given. Cod-liver oil, either alone or combined with steel wine, is a specific in doses from one teaspoonful and upwards, three times daily, half an hour after food. If it seems to disagree, it should be still persisted in, and increased at the earliest possible moment, finding the unaltered oil in the faces is an indication to lessen the dose for a time. In extreme cases when practically nothing will "stay down," it should be rubbed in freely and lint soaked in the oil wrapped round the child's abdomen. Some patients can take cod-liver oil far easier, if to each dose is added a few grains of ordinary table salt. The various cod-liver oil emulsions in my hands have not had the same success as the crude oil. The phosphorus in cod-liver oil treatment (introduced by Kassowitz) has been extensively tried and found to be no better than the oil without the phosphorus, it consists of one part phosphorus in 10,000 cod-liver oil. A very efficient mixture largely used in this hospital consists of tinct. ferri mur. 10 minims; liq. calcis chlor. B.P. 30 minims; aqua camph. 3ss., to be given three times

Mechanical.—Generally speaking, all cases of bony deformity below the age of five years can be effectually treated with light, well-padded, wooden splints fixed to the concavity of the limb by broad, soft, inelastic, cotton-web straps. The spine may have to be supported by a well-padded leather back splint. Above the ages of five years, and up to ten, light ateel supports will be needed, acting in exactly the same way as the light wooden ones. The spine at this period may require a "stoop-splint" if growth is progressing rapidly, or possibly a light steel support. Operative Treatment.—The limbs may be unbent or even "green stick" fractures produced by the surgeon's hands and afterwards restrained in plactor of Paris

hands, and afterwards restrained in plaster of Paris

This, of course, should or other convenient media. only be done when the child has been relieved of all its symptoms, except the deformities. At or above the age of ten years one of the many forms of oste-otomy will be required. Should the patient be unsuitable or refuse operation, a great deal may be accomplished in relieving deformity and giving comfort to the patient, by the use of light steel supports as mentioned under mechanical treatment.

During the latter part of the lecture a practical demonstration was given of the various mechanical means adopted for the rectification of rachitic deformities, also photographs, and may plaster of Paris casts from the hospital museum were shown.]

Clinical Records.

ST. GEORGE'S HOSPITAL.

Extensive Calcification of an Adherent Pericardium with inveterate Ascites (tapped 52 times) which was attributed to Hepatic Cirrhosis and ineffectually treated by Laparotomy and artificial production of adhesions. Unusual condition of the Peritoneum. (a)

Under the care of Dr. WM. EWART.

THE patient, æt. 49, died from the exhausting effects of frequent and repeated tappings, and of increasing anasarca and dyspness. The abdomen had begun to swell five years ago, and the legs also slightly. When admitted into St. George's Hospital in July, 1896, the diagnosis of nodular cirrhosis was made on the strength of the predominance of ascites, the enlargement of the liver, the absence of albuminuria, and of any apparent heart failure, the pulse being always good and strong, though at that time pericardial friction and an apical systolic murmur were heard, which subsequently were not again discovered. There was no history of alcoholism, but for some years as a young girl she drank vinegar from the bottle in large quantities habitually. She had had rheumatic fever at the age of 18, and twice since. She was admitted into the hospital again and again merely for paracentesis, after which the liver could be felt below the costal margin. In August, 1897, Mr. Warrington Haward carried out the operation devised by Drummond and Morison. The patient recovered, though peritonitis was set up which was almost fatal. The relief as regards the ascites was purely temporary, and the patient continued to be tapped at intervals until too weak to leave the hospital, where she died on August 17th, 1898.

The post-mortem examination showed that the pericardium was universally adherent to the heart, and was stiffened by a layer of calcareous salts to an extent which must have precluded the contraction of the ventricles. This carapace extended upwards as far as the auriculo-ventricular groove, but not over the auri-cles, which were not rigid, and their contraction may not have been much interfered with. The ventricular cavities were only slightly dilated, the membranes normal, the orifices slightly dilated. The myocardium rather thin and soft. There was no great hypertrophy of the walls of the auricles. The liver was not cirrhotic but slightly enlarged from chronic congestion, and its tissue soft and greasy without fibrosis. The other abdominal viscera formed together with it an adherent mass, from which the abdominal walls could with difficulty be detached, occupying the upper half of the abdomen. The lower half of the abdomen presented an unusual condition. No bowel was visible except the descending colon, which came into view when the large accumulation of fluid which exclusively occupied this part of the abdomen had been emptied. Into the fluid projected from above a large, spherical mass, the smooth peritoneal lining of which was continuous with that of the ascitic cavity, and almost suggested the idea of a second peritoneal sac. The spherical mass contained the bowel gathered together into a large ball. The investing

⁽a) Specimens shown at the Harveian Society of London, March 6th, 1899.

membrane was of soft consistency, and was partly torn during examination. The adherent viscera, the adhesions between which entirely obliterated the upper part of the abdominal cavity, were fairly healthy. The re-current ascites is of interest in connection with its cause, which was not cirrhosis as suspected but cardiac obstruction. Drummond and Morison have recorded a case in which at the operation the liver was found not to be cirrhosed, but the cause of the recurrent ascites was not made out, no post-mortem examination having been obtained. This case was similar to the one here described, for the patient survived the operation nineteen months and was tapped sixty-nine times.

SIR PATRICK DUN'S HOSPITAL.

Sarcoma of the Suprarenals and Secondarily of the Lung. (a)

Under the care of J. MAGEW FINNY, M.D.Dub., F.R.C.P.I., L.R.C.S.I., &c.

I am enabled to exhibit the left lung and the right and left suprarenals, which were the seat of sarcoma, with microscopical sections of the lung made and explained by Dr. O'Sullivan, lecturer in pathology, Trinity College, Dublin. The patient was a man of sixty-six years, who was admitted to Sir Patrick Dun's Hospital, October 1898, suffering from great prostration and cough, and pain in the left side. The only wellmarked signs he possessed were those of encysted left pleural effusion, without displacement of the heart, and on exploration the diagnosis was confirmed, and the fluid found to be bloody. This character, and his consti-tutional cachexia made the diagnosis to be cancerous pleurisy. The patient's colour was very dark, but without the characteristics of Addison's melasma, while the sputum was free from tubercle bacilli, and the urine from albumen. Death from exhaustion took place March 20th, 1899. The morbid specimens showed the left suprarenal to be converted into a mass of bloody sarcoma the size of a goose egg-the natural tissue of the gland was obliterated, and the sarcoma, which was unencapsuled, rested on and partly invaded the top of the left kidney, and was in intimate relation to the renal vein; from this vein a branch passed directly into the sarcoma. The right suprarenal was also converted into a sarcoma of similar character, but it was the size of a small hen's egg. The left pleura was greatly thickened and rough, and contained a quantity of bloody exudation which was strictly encysted, as had been mapped out during life; the layer of pleura pulmonalis was equally thick, and completely separated the effusion from the pulmonary tissue. The centre of the lower lobe of the left lung was a mass of soft broken down sarcoma which seemed to pass at different depths into the surrounding healthy lung tissue. The microscopical character of sections of the left kidney and of the lung showed sarcoma of a mixed character, and what was most remarkable and strange—a number of giant, polynuclear, or myeloid cells-containing as many as twelve or fourteen nuclei, and resembled exactly those found in sarcoma springing from the periosteum or ends of bone. The case presented, therefore, the rare peculiarity—not unknown in the life history of sarcoma of reproducing cells of connective tissue type, which is not that of the matrix from which it grew, inasmuch as there was a complete absence of any bone disease. The other point of interest lay in the sequence of the diseased organs. From the rarity of sarcoma being a primary disease of the lungs and the frequency of the suprarenals being the first affected, it is not improbable, as Dr. O'Sullivan suggested, that the disease originated in the connective tissue or vessels of the left adrenal, that by the open vein it passed through the left renal vein into the circulation, and directly affected the right adrenal, and by embolic infarction it found its final resting place in the substance of the left lung. The most careful examination failed to show any extension from the adrenals to, or through, the diaphragm.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD FRIDAY, APRIL 14TH, 1899.

The President, Mr. Langton, F.R.C.S., in the Chair.

WOUND OF A LARGE SUPERFICIAL INQUINAL ARTERY IN WHICH THE BLOOD WAS FLOWING FROM THE TRUNK TO THE THIGH.

Mr. Spencer described an unusual case in which. whilst laying open a tuberculous sinus in the groin an artery the size of the brachial was wounded. The bleeding was at once controlled, no complication occurred during the healing of the disease, nor was the circulation in the limb disturbed. The point at which the artery was wounded was just in front of Poupart's liga-ment where the skin and subcutaneous tissue was much infiltrated by tuberculous disease. When the two ends had been tied and the artery divided between the upper end iretracted and pulsated strongly, it was then situated immediately beneath the skin, one inch above and a little internal to the middle of Poupart's ligament, and resembled the brachial artery in an amputation stump. The lower end neither retracted nor pulsated. No accompanying vein was seen. The common femoral could be felt behind. On the opposite side an artery could be felt crossing Poupart's ligament close beneath the skin, distinct from the common femoral artery. Professor Thane had not been able to throw any light upon this anomalous vessel. The artery was clearly given off somewhere from one of the iliac arteries. and after reaching the abdominal wall, crossed in front of Poupart's ligament, to be distributed to the inner side of the thigh. The only likely explanation was that it was a superficial obturator artery. To this there was the obvious objection that the obturator artery was essentially a deep one, and that its aberrations had been closely studied in connection with femoral hernia. The provisional name, "superficial inguinal," was, therefore, employed in the absence of any information as to the origin of the vessel.

Mr. CLEMENT LUCAS suggested that the artery which Mr. Spencer met with might have been an aberrant branch of the deep epigastric artery. He had seen branches of considerable size perforating the superficial

muscles over that artery.

The President also thought that the vessel might have sprung from the deep epigastric artery, and asked from what direction it appeared to come?

Mr. Spences said that on the side operated on the tissues were so much thickened that nothing could be made out as to the course of the vessel. On the healthy side a small artery could be made out distinct from the common femoral in which blood was flowing from the trunk into the thigh. He thought that Mr. Lucas's explanation was probably the correct one.

Dr. ROLLESTON and Dr. CYRIL OGLE read the notes of THREE CASES OF SYPHILITIC STENOSIS OF BOTH BRONCHI.

Case 1.—A woman, et. 25, who came to St. George's Hospital, January 3rd, 1899, complaining of cough and loss of weight. There was stridor, but no alteration of voice. Air entered both lungs equally. Septic pneumonia developed and terminated fatally. There was fibrosis of the lungs and thickening of pleura, the bronchial glands were acutely swollen. There was a localised narrowing of the bronchi and dilatation, probably from retention of secretion, of bronchial tubes beyond. There was extensive syphilitic disease of the liver. Case 2.—A man, æt. 29, has admitted under the care [of Dr. Whiphan in November, 1896, for increasing difficulty in breathing. There was stridor, and air did not enter the left side as well as the right. The larynx was normal. Both testicles were enlarged. He was given iodide of potassum, but the dyspnœa increased, and death ensued from septic pneumonia. There was narrowing $(\frac{1}{16}$ in.) of both main bronchi, due to thickening of the bronchial wall. There was sign of recent ulceration. The tubes beyond were distended with yellow mucus. The testes contained

⁽a) Exhibited at the meeting of the Byal Academy of Medicine in Ircland, February 24th, 1899.

Case 3.—A man, æt. 29, was admitted to St. George's Hospital, under the care of Dr. Cavafy, on September 24th, 1897, for increasing shortness of breath and stridor. There was syphilitic perforation of hard palate. Tracheotomy gave no relief. At the necropsy, both bronchi were found much stenosed. There was no syphilitic disease of the other viscera. Examination of published cases showed that syphilitic stenosis of the bronchi were usually combined with a similar lesion in the trachea, and that syphilitic stenosis of the bronchi alone was rare; reference was made to four other cases of stenosis of both bronchi, and three of one bronchus, making with the three cases described that evening, ten in all. The average age of these ten cases was 36½ years, only two being above 40 years, the sexes were almost equally affected. In the cases brought forward by Dr. Rolleston and Dr. Ogle, it seemed probable that administration of iodide of potash had done harm, inasmuch as it increased the secretion in the obstructed bronchial tubes. This secretion accumulated, and by undergoing decomposition changes, set up septic bronchitis, broncho-pneumonia, and fever, from septic absorption. In order to avoid this, it was recommended that full doses of belladonna should be combined with the iodide so as to prevent the secretion of mucus from the bronchial muccus membrane.

Mr. Lucas thought that little could be hoped for from treatment in such cases, as the lesions were of a cicatricial nature like leucoplasia of the tongue and fibrosis of the testis. He had met with two cases of syphilitic stenosis of the trachea, in which the lumen was so diminished that a tracheotomy tube could not be passed down.

Dr. West said that the cases must be very rare, as he had never seen one during many years as pathologist to two hospitals. He remarked that stenosis might be due in some cases to the result of inflammation extending from the lymphatic glands.

Dr. ROLLESTON, in reply, said that he thought that the cases might be more frequent than was supposed. Out of all the cases recorded half came from Guy's Hospital, probably because attention had been drawn to their occurrence and a look-out kept. He mentioned one case in which this condition was diagnosed, and in which recovery followed treatment.

TWO CASES OF UNUNITED FRACTURE OF THE HUMERUS CAUSED BY THE INTERPOSITION OF THE MUSCULO-SPIRAL NERVE BETWEEN THE FRAGMENTS.

Mr. CLEMENT LUCAS read a paper on this subject. The first case related occurred in a man, et. 41, and the fracture, which was compound, was caused by the kick of a horse on November 12th, 1895. He was taken to a local infirmary and put up in a rectangular splint. Some sloughing of skin occurred. On Februray 2nd, 1896, an operation was performed, and a wire applied, as union had not taken place. On April 11th, 1896, he was discharged, union having still failed to take place, while musculo-spiral paralysis was established. He was admitted into Guy's Hospital on May 12th, 1896. There was a false joint at the junction of the upper two-thirds with the lower third of the left humerus and scars due to the injury and operation. The elbow was fixed in a semi-flexed condition, finger and wrist also flexed and fixed. Loss of sensation existed over the distribution of the radial nerve. The splint was removed, massage, passive movements, and electricity were applied till the movements of the elbow were restored, and some pronation and supination and partial movement of fingers and wrist were ren-dered possible, but musculo-spiral paralysis remained. On June 12th, 1896, an incision was made on the back part of the arm, and the musculo-spiral nerve was traced up to where it was found engaged between the fragments. The wire encircling the fragments was found to include the fibrous extension of the nerve. The bone was again resected and wired, and the nerve being cleared for about two inches above and below was also resected, about an inch of the fibrous part being cut away and the ends united by means of sterilised silk. Primary union of the skin wound took place, and he left the hospital soon after with the

arm in a plaster case. Three months later it was found that union was still incomplete, and the bone was again exposed, and a screw as well as a wire applied to the fractured ends, and the nerve again resected. A sinus remained as a result of this operation till November, when it closed. The bone was then firmly united, but the paralysis remained. Electricity and massage were used, and a useful arm for carrying was obtained, but the nerve had not recovered when last The second case was that of a man, æt. 30, who was admitted into Guy's Hospital under Mr. Clement Lucas's care on October 9th, 1896, suffering from an ununited fracture of the right humerus and musculo-spiral paralysis. Five months before admission, when riding a bicycle, he was run into by a cart, the shaft of which struck his right arm, causing the fracture. It was put up in splints about an hour later, and these remained on seven weeks. Afterwards for three weeks he had a poroplastic case. At the time of the accident and afterwards the patient suffered severe pain down the back of his forearm, on the outer side, extending to the thumb and forefinger. On November 15th, 1896, Mr. Lucas made an incision between the triceps and brachialis anticus four and a half inches in length on the antero external aspect of the arm, and finding the musculo-spiral nerve, traced it up to where it was engaged between the fragments. The nerve was detached, resected, and united by silk, and the fragments of bone were resected and united by a screw and an encircling wire, primary union following, and he left the hospital in a plaster of Paris case on December 6th, 1896. He returned in a month, when it was found that good bony union had taken place, and when last seen, however, though he had a useful limb, the power of extension at the wrist had not been recovered.

The President related the case of an elderly woman under his care at St. Bartholomew's Hospital, with fracture of the humerus which had led to musculospiral paralysis and severe neuralgic pain. He exposed the bone and found that there was an oblique fracture, the nerve lying behind the end of the upper fragment. The nerve was nearly divided, and there was a bulbous swelling on its distal as well as its proximal extremity, a condition that he had seen in other cases of the kind. The fracture was so oblique that he had to resect a considerable portion of the bone. He sutured the nerve and wired the bone. The state of the bone was satisfactory, but little improvement had taken place in the paralysis, and he thought that less improvement usually took place in the musculo-spiral nerve after suture than in other nerves.

Dr. SAMUEL WEST read a paper on

SKIN AFFECTIONS IN GRANULAR KIDNEY.

Rashes associated with cedema were for the most part erythematous in character, transitory in duration, produced few symptoms, and unless general, have but little clinical importance. If the skin was broken, as after puncture or when blebs have formed and burst, secondary infection might occur, and rashes of an erysipelatous character might arise, or phlegmonous inflammation or even gangrene might develop, but these were accidental events. Rashes without edema occurred almost exclusively in the course of "granular kidney." They are generally wide-spread and often universal, of great obstinacy, and of grave significance, taking the form of erythema, pityriasis rubra, dermatitis exfoliativa, general eczema, and lichen. They were rarely hemorrhagic. The following cases were described. 1. General Erythema: In a man, et. 42, under treatment for uncontrollable diarrhea. A general erythema developed which itched greatly and persisted until death. Post-mortem, no legion was found except. lesion was found except granular kidney. 2. Pityriasis rubra; two cases.—A man, at. 47, admitted for the rash and most extreme asthenia. The signs of granular kidney were well marked. He improved in the hospital but shortly after, having lost ground again, died of uremic coma. A woman of 41 admitted also for the skin eruption, and extreme asthenia. The rash in the course of time disappeared, but the asthenia continued, and she ultimately died of exhaustion. 3. Dermatitis exfoliativa.—A man of 48 admitted for the rash. He

presented clear signs of granular kidney. The rash improved, but did not entirely disappear, and the patient died shortly after reaching home. A woman of about 44 was in the hospital for a surgical affection. The rash developed; signs of granular kidney were discovered, and she died shortly afterwards of asthenia. 4. A papular lichenous eruption. One case occurred in a man of 40, which was attended with a rise of temperature, and as there was small-pox about, the question was raised as to its being one of variola to the papular stage of which it bore some resemblance. The man died soon after, and granular kidneys were found. The second case was that a weman of 52, whose chief symptoms were vomiting, diarrhœa, and asthenia, and who died in uræmic coma. The rash appeared fourteen days before death. It rapidly spread over the whole body. The papules were in some parts as large as a split pea, and resembled urticaria. In a third case, a girl, et. 20, the papules were of small size, and developed twelve days before her death. In this case also the chief symptoms were vomiting, diarrhœa, and asthenia, and she also died comatose. He remarked that the cases in which these rashes appeared almost invariably ended fatally, and that usually soon. The rashes occur only late in the disease, and when the signs of granular kidney are well marked, though its existence is not infrequently overlooked. I'he association of a generalised skin-eruption with albuminuria is of great importance, and if the cause of the albuminuria be granular kidney, it is of the gravest signifi-cance, for the patient will soon die, not of the skin affection, but of the granular kidney.

Dr. H. D. ROLLESTON said that he had seen some of the cases published by Dr. Le Cronier Lancaster, quoted by Dr. West, and had made examinations of the kidneys. In the production of these eruptions there appeared to be some toxic factor, which was not uramic, or the rashes would not be so rare. Possibly in some cases drugs might be the exciting cause, and in others some intestinal poison, and in this connection it was of interest to note that several of Dr. West's cases suffered from diarrea. Possibly in the cases of extensive dermatitis there was a secondary constitutional infection, such as occurred in connection with the pleural and pericardial serous membranes in advanced cases of Bright's disease. He asked whether there was any connection between this condition and the epidemic skin disease which was attributed by Dr. Savill to an organism. Flexner had observed that persons suffering from chronic diseases seldom died from their direct effects, but usually from secondary infections, and had further found that the blood of meu dying from some chronic disease had a much weaker germicidal action than that of a healthy man.

Dr. Colman mentioned a case of a papular lichenous eruption occurring in a tabetic patient, which closely resembled that in one of Dr. West's cases, and which was also suspected to be one of small-pox in its early stage. There was intense itching, and the patient died from asthenia after a few days' illness, and as the necropsy advanced granular change was found in the kidneys. Like albuminuric retinitis the occurrence of those eruptions appeared to be of very grave significance.

Dr. Longhurst mentioned a case under his care in which purpura had occurred in the legs of a patient suffering from advanced Bright's disease.

Dr. Toogood said that the epidemic skin disease mentioned had been prevalent in many of the infirmaries, but that the majority of superintendents held that it was not due to an organism, but to some toxin taken with the milk, as all the affected infirmaries were supplied by the same firm, and when the milk supply was changed there were no more cases.

Dr. West, in reply, said that the object of his paper was to draw attention to the occurrence of these eruptions, and not to explain the mode of production. in the present defective state of our knowledge of what uræmia was, he thought that it would be rash to say that they were not due to some of the conditions at present grouped under that term. He had no doubt that the acute and chronic forms of uremia, for instance, were due to different poisons, and that these eruptions belonged to the more chronic forms.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF PATHOLOGY.

MEETING OF FRIDAY, FEBRUARY 24TH, 1899.

The President, J. M. PURSER, M.D., in the Chair.

PNEUMOCOCCAL SEPTICÆMIA WITH ULCERATIVE ENDO-CARDITIS CONSECUTIVE TO CROUPOUS PNEUMONIA.

DE. McWeeney communicated an observation bearing on a man, et. 37, who was admitted on Dec. 5th. 1898. to the Mater Hospital, under the care of Dr. Murphy, with right apical pneumonia. Crisis occurred on the ninth day, and was attended with a good deal of collapse. Ten days afterwards patient was allowed up one evening and got very weak. On January 1st, an aortic systolic murmur developed which became very loud, patient became prostrate and delirious, the temperature curve assumed a pyæmic type, and death ensued on January 5th. On the 2nd blood was taken, with strict precautions, from the finger, and inoculated by means of a pipette on several tubes of oblique glycerine agar. After twenty-four hours incubation at 37°, one of these tubes presented a few extremely minute dewdrop-like colonies which proved to consist of Frankel's pneumococcus. The other tubes remained sterile. At the autopsy (forty-eight hours after) blood was aspirated from the right auricle into a sterile bulbed pipette, and inoculated on agar tubes. Owing to the solid coagulation, but little liquid could be obtained. The incubated tubes showed numerous large circular colonies, like discs of porcelain (probably the Bacillus coli) but also very many minute whitish, very delicately fringed colonies, which proved to be the pneumococcus. A broth culture from one of them, after twenty-four hours at 37°, was scarcely turbid, yet 1 c.c. injected intraperitoneally into a rabbit caused death in seventeen hours. Pneumococci with typical capsules were in the blood of every organ examined. other post-mortem results were briefly: pericardium universally obliterated by recent adhesions, parietal layer being readily stripped off; myocardium of auricles soft and friable like wet blotting paper. Right posterior cusp of aortic valve presented a mass of vegetations as big as a herry—colour, greyish green where not covered with clot; behind this the cusp perforated, hole would admit an ordinary pen handle. Grey hepatisation of most of the right lung. Spleen twice the natural size, infarcted throughout. Embolus in primary branch of splenic artery, fibrinous, crammed with pneumococci.

CASE OF HODGKINS' DISEASE.

Dr. J. B. Coleman read notes of a case of Hodgkins' disease, which was remarkable for the acute clinical course, and for the widespread distribution of the lesions. The patient, a labourer, et. 50, had enjoyed good health up to eleven weeks before his death. He gave no history of alcoholism or syphilis. Glandular enlargements first appeared in the left cervical and axillary regions. On admission to hospital, three weeks before his death, he was somewhat emaciated, but not anæmic; skin dry and scurfy; pulse and temperature normal; all the superficial glands were considerably enlarged, and there was evidence of enlargement of the thoracic and abdominal glands also; the glands were soft, freely movable, and painless; spleen was easily palpable and liver dulness increased. Examination of the blood showed hæmoglobin and red cells normal, the white cells 11,200 cubic m.m.; 40 per cent. of the white cells being lymphocytes; the blood contained no micro-organisms. The patient rapidly became more and more prostrate, temperature was usually normal or subnormal, but on three occasions in three weeks it mounted to 100.5; his appetite failed, he became delirious, and died with symptoms of toxemia eleven weeks from the onset of the disease. necropsy disclosed universal enlargement of the superficial lymphatic glands, as well as of the mediastinal, retroperitoneal and mesenteric glands; adenoid nodules were present in kidneys, spleen, liver, and intestines; the spleen was greatly enlarged, and growing from its capsule, as well as from that of the liver, were large masses of adenoid material; below the liver the retroperitoneal glands were enlarged and massed into a tumour, which surrounded the aorta and involved the adrenals. Cultural and inoculation experiments were carried out with the assistance of Dr. McWeeney with negative results. Dr. Coleman mentioned the arguments in favour of Hodgkin's disease being cf an infective nature, and pointed out that numerous observers had found micro-organisms in the diseased glands. He also contrasted the disease with leucocythemia, and said that Cohnheim regarded Hodgkin's disease as an aleukemic vorstadium of leukemia, whilst numerous observers had noted the transition of the one disease into the other.

Dr. E. J. McWeeney confirmed the negative results of bacteriological culture and asked if there was any history of suppuration, syphilis, or tuberculesis to account for the lardaceous disease.

Brigade-Surgeon Lieut.-Col. Burke said when at Gibraltar and Malta he had seen many specimens of amyloid degeneration, and the liver specimens now exhibited were very like those he had seen due to syphilitic disease.

Dr. COLEMAN, in reply, said that there was no history of syphilis or long-continued suppuration. Regarding the cardinal symptom of anæmia, he said that anæmia is not necessarily a part of Hodgkin's disease, and only becomes marked as the case progresses. Anæmia has been absent in undoubted cases of the disease.

BPITHELIOMA OF LIP FROM YOUTH EIGHTEEN YEARS OLD.

Mr. G. Jameson Johnston read the notes and exhibited microscopical sections of a case of epithelioma of the lip in a youth eighteen years of age.

BREAST CONTAINING NEW GROWTH REMOVED FROM YOUTH SEVENTEEN YEARS OLD, WITH MICROSCOPIC SECTIONS.

Mr. Johnston also exhibited the left breast of a male patient, containing a new growth in the left upper quadrant, about the size of a large walnut, radiating processes of the growth extended in every direction into the gland substance; the consistence of the mass was quite firm, and to naked-eye examination very like scirrhus. It had been steadily growing for three months in spite of medical treatment, causing some slight discomfort, not actual pain; there was no retrac-tion of the nipple or dimpling of the skin; the glands along the lesser pectoral were palpable before operation. No history of injury could be obtained. The whole breast and connective tissues and glands along the pectoralis minor were removed. The wound healed by first intention. At the present time (twelve hours after operation). No recurrence can be seen nor any enlarged glands felt. Microscopical examination showed the growth to be mainly fibrous tissues, with what appears to be a few short columns of gland cells here and there.

Dr. A. C. O'SULLIVAN thought that no one could doubt that the first section was a squamous cancer.

Dr. E. H. Bennert said that there was a similar case of epithelioma of lip in youth of 18, described in Pott's works.

Dr. E. J. McWeeney considered the epitheliomatous nature of the lip tumour most typical.

Mr. G. J. Johnston, in reply, doubted if the tumour of the lip recorded by Pott as epitheliomatous was really

such in the absence of precise pathological investigation.

Mr. J. MAGEE FINNEY showed specimens from a case
of "Sarcoma of the Suprarenals," which will be found

under "Clinical Records."

Dr. E. J. McWeeney said that some of the sections showed a very marked resemblance to tissue which he found in the kidney as the result of an aberrant suprarenal growth originating from an aberrant fragment of suprarenal. The curious thing seen in the section was the presence of enormous giant cells, entirely like the myeloid cells of bone.

Dr. E. J. McWerney (for Dr. Cole Baker) showed a melanotic sarcoma of choroid.

Dr. Knorr demonstrated an extensive series of pathological fibulæ and patellæ.

and member of Council of the Medical Defence Union

HARVEIAN SOCIETY OF LONDON. MEETING HELD THURSDAY, APRIL 6TH, 1899.

H. A. CALEY, M.D., in the Chair.

CLINICAL EVENING.

EXCISION OF MALIGNANT GROWTHS OF LARGE INTESTINE.

Mr. W. H. BATTLE showed two female patients on whom he had operated for distension due to malignant growth of the large intestine. The first was a case of growth in the splenic flexure with the gradual onset of symptoms for four weeks. She was twenty years old, and as there was extreme distension so that it was impossible to bring the growth to the surface, and inadvisable to prolong the operation, a temporary colotomy was done under the left lower ribs. At operation, five weeks later, excision of growth, and artificial anus, with lateral anastomosis, was done. This was in September, 1898. The second was a woman, st. 46, for whom operation for distension was done in August, 1898, and a columnarcelled carcinoma of sigmoid flexure treated by Paul's method. Subsequent attempts to get rid of the spur were painful and tedious. Ultimately a lateral anaetomosis was done, and the artificial anus closed. Both patients had now a regular action of the bowels, and looked remarkably well, whilst the scars were firm without any tendency to weakness or hernial protrusion.

In answer to Mr. Raymond Johnson, Mr. BATTLE said that in his experience the best results in excising portions of intestine were obtained by completely closing the ends of the bowel, and then establishing a lateral anasto-

SYRINGOMYELIA WITH PHARYNGEAL AND LARYNGEAL LESIONS.

Dr. HERBERT TILLEY showed a case of syringomyelia in a girl, æt. 15, in which there was paresis of the right half of the palate, pharynx and right vocal cord. Other points of interest in the case were the blunting of painful, and the complete loss of thermal, impressions all over both superior extremities and certain well-defined areas of the neck and trunk, atrophy of the small muscles of the hands, the latter exhibiting the main en griffe position, moderate wasting of the flexors and extensors of the wrist and slight nystagmical jerks of both eyes (for fuller details vide Proceedings Laryngolog. Society of London, December, 1898). A painless but severe burn on the hand and a gruffness of the voice with some difficulty in swallowing first led the patient to seek advice. The pharyngeal and laryngeal condition have much improved during the past two months, during which time the patient has been taking strychnia.

COMPLETE PARALYSIS OF LEFT SPINAL ACCESSORY NERVE.

Dr. HERBERT TILLEY showed a man, æt. 55, who, in October, caught cold and became hoarse, and at the same time experienced an accumulation of, and difficulty in expectorating, saliva. He managed, however, to fulfil his engagement as a preacher. There was slight difficulty in swallowing. No history of gout, syphilis, or rheumatism. Examination showed the left side of the palate, pharynx, and left vocal cord, the left sterno-mastoid, and upper part of the left trapezius to be completely paralysed. At the onset of his trouble the patient had had no pain, giddiness, or general symptoms beyond those due to the cold, and the exhibitor agreed with the President that the case was probably one of pachymeningitis involving the trunk of the spinal accessory nerve after the cervical and spinal portions had united within the skull.

PARESIS OF LEFT SIDE OF PALATE, PHARYNX, LEFT VOCAL CORD, AND RIGHT SIDE OF TONGUE.

Dr. HERBERT TILLEY showed a, female, set. 31, exhibiting these conditions. In October, 1898, she suffered for two to three weeks from very severe pain over the back of the head and neck terminating in "fits," details of which are not obtainable. In the first she fell down, but did not lose consciousness; in a second fit, three Dr. Arthur P. Luff has been elected a vice-president | days later, she lost consciousness, was hoarse on recovery and paralysed in the left arm and leg, with some weak-

ness of the left side of the face. She was in bed for five weeks, and at first was sustained by nutrient enemata as swallowing was impossible, fluids being ejected through the nose. Food was then administered by stomach pump, her condition improved, the arm and leg recovering power, but the throat condition remains the same. When first seen by the exhibitor there was, in addition to the above throat lesions, slight paresis of the left lower facial muscles, protrusion of the tongue to the right (slight), contraction of the left pupil, and a small warty growth on the mucous membrane of the right arytenoid cartilage. It is difficult to conceive of any single lesion which would explain the various conditions found in the case. Dr. Tilley remarked on the rarity of laryngeal or pharyngeal paralyses in syringomyelia, the slight effect on the voice of paralysis of one vocal cord, and the way such cases as these tended to support experimental evidence that the spinal accessory supplies the muscles of the palate, pharynx (partial) and

SPASMODIC TORTICOLLIS.

Mr. Noble Smith showed a patient, et. 21, upon whom he had operated for spasmodic torticollis by excising a piece of the spinal-accessory nerve just above its entry into the sterno-mastoid muscle. This was on the right side. He had previously operated upon the left side four years ago. Both operations had been successful, and it was remarkable that on the left side (the first operation) the function of the nerve had been restored six months subsequent to its division. It had been necessary on that occasion also to divide the external branches of the second, third, and fourth cervical nerves on the right side. The patient had gradually improved in health and strength, but recently some spasms had developed in the right sterno-mastoid. He had subjected the patient to a course of special exercises and massage which had still further strengthened her, but this treatment had not relieved the spasm, so he had recently operated on the right spinal accessory. The patient had been able to be up and about six days after the operation. She was exhibited at the meeting, and it was found that the right sterno-mastoid and the upper portion of the trapezius were completely paralysed, but that the patient was in no way inconvenienced by this loss of power.

In discussing the above cases, Dr. LEONARD GUTHRIE referred to the regression of symptoms which had occurred in Dr. Tilley's case of syringomyelia. In 1896 he (Dr. Guthrie) had shown before the society a woman, æt. 28, who had nystagmus, complete analgesia, and thermo-anæsthesia with bloated tactile sensation of the whole of the left upper extremity and left side of the head, fore neck and chest to level of third rib. She had also paralysis of the left side of the soft palate, and of the left vocal cord. The analgesia, &c., had followed immediately a violent attack of sneezing, three months' previously, whilst paralysis of the spinal accessory occurred immediately after an attack of coughing two months later. In the course of about a year these symptoms had to a great extent disappeared. He attributed the sudden onset of symptoms to hæmorrhage in or near a syringomyelic cavity and their subsidence to its absorption.

The cases were also discussed by Mr. Jackson Clarke and the Chairman,

CALCIFICATION OF ADHERENT PERICARDIUM WITH INVETERATE ASCITES.

Mr. W. EWART showed specimens from a case, and gave details thereof which will be found under "Clinical Records."

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY MEETING HELD THURSDAY, MARCH 16TH, 1899.

The President, Dr. Alfred Robinson, in the Chair.

MR. SIMEON SNELL exhibited the following patients: 1. Coloboma of iris, two cases, one extending through choroid, one confined to iris. 2. Tumour of each orbit, probably extending across the septum; a stereoscopic photograph was shown. 3. Optic atrophy (post-neuritic) after influenza.

Mr. Snell also showed the following nine sections of eyes, with tumours:-Three of gleniea, one an instance in which the first affected had been removed two years previous to the appearance of the disease in the second eye. A case of concurrence of globi, apparently commencing in the cornes. Five instances of sarcoms of the choroid, one a leuco-sarcoma, in an old man, two in young men, one a middle-aged man, one in a middle-aged woman.

Mr. Sinclair White exhibited and made remarks on 1. A woman from whose bladder he had excised a cancerous tumour nine months ago. The growth was about one inch in diameter, and grew around the entrance of the right ureter. It was removed through a suprapubic wound, together with the entire thickness of the bladder wall. To prevent urinary extravasation a dependent opening was made into the vagina. The resulting vesico-vaginal fistula was closed three months later. The patient was now free from recurrence, performed her vesical functions perfectly, and was much improved in health. 2. A case of paralytic talipes equinovarus treated by transferring the tendon of the tibialis posticus and the outer third of the tendo-Achillis to the tendons of the common extensor and the peroneus anticus muscles. The result achieved was remarkably good. The patient was a boy, et. 10. 3. Four cases operated on for undescended testicle, In each case after free division of the cremaster muscle and incision of the tunica vaginalis a silkworm ligature was passed through the tunica albuginea at the lower end of the testicle, and both ends of the ligature passed through the base of the corresponding side of the scrotum, and fastened to the thigh by means of strapping. 4. A woman cured of a suppurating pelvic cyst which had discharged into the bladder for four years. The cyst was in the first instance opened and drained suprapubically; but as the sinus did not close it was subsequently successfully dealt with by draining it into the roof of the vagina. 5. Cases of excision of the into the roof of the vagina. 5. Cases of excision of the knee and ankle. 6. Cases illustrative of diseases of the

Mr. Pye Smith read notes of a case of "Traumatic Dislocation of the Hip" on to the dorsum ilii in a boy, æt 5. It had been produced by a fall during a scuffle with another boy, and was easily reduced by manipulation under chloroform.

Mr. Pye Smith also showed a sequestrum of bone forming the nucleus of a vesical calculus removed by median lithotomy from a man who had sustained fracture of the pelvis from a crush in a coal mine two years pre-The sequestrum had probably entered the bladder about a month before its removal.

The President, Dr. Keeling, Dr. Wilkinson, Mr. Pye Smith, Dr. Sinclair White, Dr. Addison, Mr. Dale James, and Dr. Hargreaves made remarks,

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, April 16th, 1899.

OSSIFICATING ROLE OF THE DURA MATER.

AT the Academie de Médecine M. Chipault spoke on the rols of the dura mater in repairing the osseous tissue of the cranium. He said that he was always opposed to cranial operations leaving intact the dura mater subjacent to the osseous orifice. He had the conviction that those of his patients he had trephined, and in whom he had removed this membrane, gave him results much superior to those in whom he had left it intact or sutured after incision. He was glad to be able to state clinical facts confirmed his opinion, for they showed that in those operations where the dura mater had been preserved intact the osseous obliteration of the loss of substance was produced over the entire surface, whereas it was not produced where it had been destroyed. Of nine cases of old traumatism, three patients suffering from lesions of the cranium of an apparently slight character, were not operated on; two of these were at present the subjects of Jacksonian epilepsy, while the third presented mental trouble. The other six were trephined, as they all presented before the operation epileptic symptoms; in three the dura mater was untouched; the occlusion of the loss of substance was effected by a hardened and probably osseous plate. In the three remainder, the dura mater was removed, reossification did not take place, and the epilepsy was cured; two of these were children, one of which presented an interesting history. It was a girl, æt. 10, in whem, after a fracture of the left side of the head, produced by a fall from a one-storey window, hemiplegia of the right side had developed, as well as a cephalo-hydrocele. This latter was opened, and the rent in the dura mater sutured. Some time after this operation, the child was seized with epileptic fits, which continued for a year at more or less long intervals. Another operation was advised and accepted; this time the cranium was resected in the region already repaired, after the first intervention, and a portion of the dura mater removed. Since that moment (a year and a half ago) the epileptic fits had ceased.

M. Chipault communicated six other cases of essential epilepsy, in all of which the dura mater was preserved, with the result that when ossification was completed, the primary affection returned, and concluded, in the great majority of operations for recent or ancient traumatisms, followed by Jacksonian epilepsy, in interventions for essential epilepsy for microcephalos or intracranial neoplasms, that, first, the ablation of the bone should be complete, and, secondly, the removal of the dura mater subjacent to the orifice should be definitely removed. Only by such means could a permanently favourable result be obtained.

Dr. Bra, of this city, is the most recent claimant for the distinction of having discovered the elusive organism of cancer. He even entertains hopes of elaborating a curative serum. He states in the La Presse Medicale that he has succeeded in isolating and cultivating a parasite from cancerous tumour. On inoculating animals with these cultures he has produced cancer. He adds that the parasite belongs to the family of actinomycetes fungi. Pending more precise details it would obviously be idle to speculate on the value of the alleged discovery. We have seen so many generations of alleged "cancer microbes" bite the dust that while we admit a hope we must refuse credence. Even if we were satisfied that the incriminated fungus was the causa causares it it still a far cry to prophylactic or curative measures.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 14th, 1899.

THE PROPHYLAXIS OF CANCER OF THE UTERUS.
PROFESSOR DUHRSSEN has a paper on the subject in the D. M. Wochensch, 499. He agrees with other authors that cancer is rapidly increasing in Germany as well as in other countries, and this in spite of improved surroundings of the people. Out of 25 millions of females in the German Empire 25,000 die annually of cancer of the uterus. Of women between the age of 46 and 502 per cent. die of the disease—a mortality equalling that

of the whole German army in the war of 1870 and 71, and removal of the disease by operation does not materially lessen this mortality. Only from 10 to 30 per cent. of all cases are fit for operation when first seen, and of the small number operated on only a third or a fourth part remain free from recurrence of the disease.

A means of improving this condition of affairs would be afforded by early diagnosis, but this is scarcely possible under present circumstances of public education, &c.. Some means of preventing the onset of cancer would be more desirable still, some means of acting on the uterine mucous surface in such a way that cancer would not develop, and the author thinks there is such a means, and that the destruction of the mucous membrane by means of Sneguireff's vaporisation. By means of this procedure, which is not painful and absolutely free from danger, necrosis of the mucous membrane is effected. The same object can be attained in another way. This is to open the abdominal cavity, through the anterior vaginal arch, and draw down the body of the uterus; the anterior uterine wall has then to be split, and the mucous surface removed. The portion can also be removed at the same time. The operation he does not consider likely to be dangerous He considers that great security against the occurrence of cancer would be afforded by Schröder's high amputation of the cervix, and this is a more reasonable proposal, as the operation is practically free from danger, and it would effect the removal of that part of the uterus in which the disease commences in nine cases out of ten. The proposal will, no doubt have the effect of leading the gynæcologist to consider favourably the removal of the cervix when it can be no longer of service, and when a possible danger may lie in its retention.

At the Society for Innere Medizin Hr. A. Fraenkel related a case of

GANGRENE OF THE LUNG TREATED BY OPERATION.

The patient, a labourer, æt. 33, was attacked with febrile lung symptoms in October of last year. In November his breath became offensive, and on December 8th sudden acute symptoms came on, a stitch in the right side and fever. In hospital the expectoration of stinking sputa reached about 300 ccm., and even to the naked eye it plainly contained lung constituents in large There was great emaciation and loss of strength, and the case had a very unpromising appearance. Operation was decided on between the speaker and the surgeon Körte, as both agreed that an extensive destructive process was going on in the right chest-Two circumstances favoured operation: one was that the disease was in the upper lobe and easily accessible, and the other, the large quantity of expectorated material which implied a large cavity which would be easier to find than a small one. He pointed out the happy results that had followed surgical interference in some lung diseases, especially in acute and solitary abscesses. In cases of multiple abscesses the prognosis was more unfavourable in such as followed influenza pneumonias. In gangrene of the lung also a distinction must be drawn between acute and chronic cases, the first starting from abscesses giving the best results. In the case before them, the clinical history showed that the disease began in an acute abscess. The original disease was influenza, but the multiple patches of disease were limited to the upper lobe, and they had probably coalesced. The speaker had not made an ex-

ploratory puncture, first on account of the danger of infecting the pleural cavity, and, second, because in such cases with large cavities there was danger of fatal hemorrhage from puncture of large vessels.

Hr Körte said that even after making several examinations of the patient he could not satisfy himself as to the existence of a cavity, but on account of the large quantity of expectorated material, he determined to operate Operation January 10th. The first, second, and third ribs were extensively resected. The pleura was found The lung was opened by a large transverse suture with the cautery, and a large cavity was laid open from which, however, no air was expelled. A spouting vessel was ligatured. A large quantity of feetid pus escapedifrom the cavity, a sequestrum of lung was removed, establishing a communication with the large bronchi. A large branching vessel running across the cavity was ligatured in two places and removed. The cavity was now packed with iodoform gauze previously dipped in balsam of Peru. The course was favourable, cicatrisation went on well, and the opening now remaining was small. The cavity reached from over the clavicle to the 3rd rib, so that happily the opening was made in the lower part, whereby drainage was facilitated. In an earlier case in which the speaker only had charge of the after treatment, the cavity became covered inwardly with epithelium continuous with that of the skin, a fistulous track remaining. On admission the patient had large drumstick-like swellings on the finger-tips, but those had now become a good deal smaller. He had only had one other case in which he had operated, one in which there were multiple cavities, a proof considering the great material of the hospital, that cases suitable for operation were rare.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, April 14th, 1899. BALNEOLOGICAL CONGRESS.

Under the auspices of Professor Winternitz, the Balneo-Klimito-and Hydro-Therapeutic Association met in Vienna this year, and passed off with great success. At the plenary meeting Winternitz heartily greeted the Association on behalf of the medical faculty of Vienna, while Von Kusy welcomed them in the name of the Austrian Government.

Winternitz read a long paper on the benefits of Hydrology, which he described as one of the most important branches of medicine. At the various congresses held in Russia, Germany, Italy, and France, the subject had been sub divided into balneology, climatology, and hydrology, which was a literary convenience in discussing and estimating the value of hydrology. Under the protection of the Austrian Emperor he was confident this branch of medicine would soon flourish as a department of scientific therapeutics.

THE INFLUENCE OF BALNEOTHERAPY ON THE CIRCULATION.

Prof. Kisch next introduced the subject of the influence of balneology on the circulation. The various results, he said, of warm baths on the circulation have been the subject of criticism since the days of Galen. It is only within the last ten years that anything like scientific methods of research had been brought to bear

on the beneficent or injurious effects of baths on the system. The classic names associated with this progress are O. Naumann, M. Schüller, and Kolman Müller.

In enumerating the results of these investigations, he observed that warm baths dilated the peripheral vessels, and then action in this respect persisted longer than that of other causes of relaxation, the frequency of the pulse is augmented, and the temperature of the body consequently raised. After the bath a compensatory recession in the circulation occurs, and if the bath be not too warm the tonus of the cardiac muscle is increased.

Mineral baths, warm or cold, had other advantages, both local and general. The gases and chemical substances contained in the waters had a useful local effect on the skin, which reacted on the reflex movements, and thereby exerted a regulating influence on the heart. The absorption of carbonic acid had a stimulating action on the nervous system and cardiac movement, and this, of course, influenced the circulation. Buth these actions could be demonstrated by temperate mineral water. As the peripheral stimulus gave rise to a flow of blood to the surface, the blood pressure was raised, the systole full and prolonged, while the tonus of the cardiac muscle was greatly accentuated. He showed that this was the principle on which the action of the acid, iron, and mud baths could be explained.

The value of the internal use of these waters was indisputable in cardiac affections and diuresis was increased. Similar advantages could be obtained by immersions in medicated waters.

CLIMATOLOGY.

Clar gave an extensive review of the effects of climate on the human organism. It had the effect of removing water from the blood by means of perspiration, increasing diuresis, while rarefaction of the air modified the blood pressure and pulsation. Mountain residence was an effectual method of curing anemia dependent upon the circulatory system. For this purpose the height should not be too great.

THE ACTION OF HYDROTHERAPY ON BLOOD AND CIRCULATION.

Strasser contributed a long paper on the clinical aspects of hydrotherapy, its applications and effects. He dwelt at great length on the effects of heat and cold as stimuli on the quality of the pulse and the corpuscular elements of the blood. He had repeated Winternitz's experiments, and was enabled to confirm his results by showing patients in whom the specific gravity of the blood, colouring matter, and corpuscular elements were all increased by hydrotherapy alone. He reviewed Winternitz's theory, according to which the change is simply due to the change in the constituents, he himself holding that the action of increased distribution was largely responsible for this beneficent alteration in the component constituents of the blood. The ebb and flow in the various organs brought about spontaneous changes in pathological functions, whether depending on humoral, solid, or cellular pathology.

KATATONIA.

Haveroch exhibited two cases of katatonia, which, according to Kahlbaum, is a disease of the central nervous system of a cyclical nature. The symptoms were usually melancholia, stupor, mental confusion, and idiocy. Haveroch preferred to describe the symptoms as "verbigeratio, mutacismus, and negativismus." He was convinced that katatonia was a distinct disease, and

belonged to dementia precox in the following order:— 1st, Dementia simplex; 2nd, hebephrenia; 3rd, katatonia; 4th, dementia paranordes, and dementia epilepticorum.

JOSEF ENGEL.

Another of the Vienna landmarks has passed from this life in the person of Prof. Engel. He had reached his eighty-fourth year, and though long ago retired from active practice, he took a deep interest in all things medical up to the last.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

SUCCESSFUL OPERATION IN A CASE OF PYÆMIA.—The following case shows the advantage of the method of operation in a case of commencing pyæmia due to absorption of material from a septic focus in the extremity. The principle of treatment is the same as that which guides the surgeon in operation for septic thrombosis of the lateral sinus due to disease of the ear. The patient a boy, æt. about 10, had been operated on for disease of the foot on account of severe talipes; the wound had become septic, and at the time of operation the lad had passed into a very serious condition. There had been high and irregular temperature for some days, he had been emaciating rapidly, was constantly calling out and was very restless. On two occasions, at a short interval, he had had severe rigors with a rise of temperature to above 105 degs. F. The pulse was very rapid and small, the tongue was furred and dry, he was rapidly going downhill, and it was evident that he could not live long unless something of a radical nature was done. Mr. BATTLE, who was in temporary charge of the case. advised that the leg should be amputated (it was extremely atrophied from results of congenital talipes), and it was not possible to say how high a purulent thrombus was extending up the limb; advised that the common femoral vein should be ligatured at the same time. Mr. Wallace, the resident assistant surgeon, applied two ligatures to the vein in the groin, after which Mr. Bingham, the house surgeon, amputated the leg in the middle third. It was not evident that there was a thrombosis in the veins of the stump, but it was not improbable that it was so, as the stump suppurated, although the wound in the groin healed satisfactorily; both had been treated with strict aseptic precautions. The ultimate result was very satisfactory, and the patient left for a convalescent home about three weeks afterwards. The case illustrates the method referred to above, and is of special interest, as this method has seldom, if ever, been carried out. It has doubtless suggested itself to many surgeons, but opportunities of trying it are almost nil. Whether it should be tried more frequently in cases of pyæmia associated with acute bone mischief or not is a question for consideration. Many cases of acute osteomyelitis of the tibia are brought into hospitals suffering from pyæmia, and it is possible that a ligature of the main vein of the limb conjoined with amputation would give better results than those obtained by amputation alone. In cephalic cases the results of ligature of the main highway from the head. with removal of the miscrief, have been in some cases almost startling in their success, and in inciances similar to that above recorded similar measures may prove of equal value.

ST. MARK'S HOSPITAL FOR RECTAL DISEASE.

PROCTORRHAPHY FOR PROCIDENTIA RECTI. - Mr. SWINFORD EDWARDS operated on a married woman, set. about thirty, who was the mother of several children. For years she had been the subject of prolapse of the rectum, for the cure of which she had undergone no less than three operations in various London hospitals. On examination, after the administration of an enema, it was found that she was suffering with true procidentia, that is to say, there was prolapse not only of the mucous coat but also of the muscular. The gut protruded for about three inches. There was practically no sphincter, for on separating the buttocks before prolapsus had taken place, one could with ease see some inches up the rectum. Of course she suffered at times with incontinence of flatus and The patient having been placed under the influence of an anæsthetic in the left lateral decubitus, a posterior median incision was made as though for excision of the coccyx, but prolonged down to within an inch of the anus. The posterior wall of the rectum was now freed, which manœuvre was greatly facilitated by a finger in the gut, which not only brought the muscular coat of the bowel wall up into the wound but also was effectual in restraining prolapse. A straight needle, armed with a fairly stout silk ligature was now inserted transversely through the muscular coat of the bowel, taking up about an inch of muscular tissue and being passed as near the lower part of the exposed gut as possible. The needle was then passed through the ligamentous structures lying to the left side and back of the coccyx. The other end of the thread, which had been left. long at the point of original entry now threaded in another needle and passed in the same manner through the ligamentous structures on the right side and back of the coccyx. On traction being made on both ends of the ligature it was found that the bowel was drawn up, or in other words anchored, to the coccvx. Before tving the ligatures and with the bowel held in this position Mr. Edwards found that ordinary efforts to produce a procidentia by artificial means failed. The ligature having then been securely tied, the wound was washed with sublimate solution, sutured without drainage, and the usual antiseptic dressings applied, instructions being given to remove these on the following day, and in their place to apply a collodion dressing in order to prevent, if possible contamination of a wound so close to the anus. Mr. Edwards remarked that this was the first time this operation had been performed at St. Mark's, and, as far as he knew, in Great Britain, and therefore he could give no definite prognosis, although from the effects shown before closure of the wound he anticipated the best results, at all events, as far as the muscular coat was concerned If there should be a subsequent prolapse of the mucous coat this might be treated either by the cautery or by excision. The points in the steps of the operation on which he laid special stress were: First, sufficient freeing of the posterior rectal wall; secondly, the application of the suture to the lowest possible point of the rectum, so that the subsequent bracing of the part may be more effectual. He also said that in order to get a good hold for his ligature he took care to pass the needle not only through what ligamentous structures he could find on the dorsal and lateral aspects of the coccyx, but also he made it include the periosteum—that is to say, all tissues

THE MEDICAL PRESS.

down to the bone itself. The reason he selected a straight needle in passing the suture through the rectum was that with it he thought it would be easier to take up a greater width of the muscular wall of the gut than he could have done with a curved instrument. A curved needle, however, was more handy for passing the ends of the ligature through the place of anchorage.

It is satisfactory to record that two days after the operation all was going well.

WEDNESDAY, APRIL 19, 1899.

OOPHORECTOMY AND THYROID TREATMENT IN CANCER.

THE effects of the menopause on the generative apparatus, and on the breasts in particular, suggested to certain enterprising surgeons some time since that malignant growths of the breast might be favourably influenced by an artificially induced menopause, as for instance, by ablation of the ovaries. On the whole the results of the operation, though not devoid of interest, have not proved quite as successful as had been hoped. Subsequent observations by a method in which the administration of thyroid extract was associated with removal of the ovaries have given much more promising results, though one is quite at a loss to explain the modus operands of the combined treatment or to apportion the relative merits of the At a recent meeting of the Medical two factors. Society of London, as reported in our last issue. Dr. G. Herman recorded a second case in which this operation, plus the administration of thyroid gland. had given results so successful as to be remarkable. In this particular case the treatment had brought about the healing of a large carcinomatous ulcer of the right breast which had recurred after two operations for removal by surgical means, and had determined the disappearance of a large tumour in the other breast, the nature whereof was suffi-

ciently indicated by the enlargement of the corresponding axillary glands, which glands also had ceased to be perceptible to the touch. results are sufficiently remarkable to merit attention especially in view of the unsatisfactory results of purely surgical measures which are at best but palliative. Mr. Stanley Boyd inclines to the view that the improvement is really due to the oophorectomy, but statistics hardly bear out his contention, for Dr. Herman had no trouble in showing that the results after oöphorectomy alone were not nearly as good as when the thyroid treatment is superadded. Further experience will show which of the two factors plays the most important role in producing these results. It seems, however, that oöphorectomy, if it is to be of service, must be done before the cessation of menstruction for, in several recorded instances, no effect has followed their removal after the menopause. This is what one might have anticipated, though from another point of view it seems odd if the artificially-induced menopause exerts such a marked effect the natural process should not confer similar quasi - immunity against cancer. fact tends to support the view that oöphorectomy alone is not sufficient to determine a constitutional change capable of inhibiting malignant growths. Dr. Herman suggests that the withdrawal of the ovarian secretion and the presence of an excess of thyroid secretion render the tissues less amenable to the ravages of the hypothetical parasite of cancer, and this explanation is in accordance with the results so far obtained. Has excessive thyroid secretion any direct influence in conferring immunity against cancer? This question ought not to be difficult to answer, for we have only to ask ourselves whether on the one hand women who suffer from exophthalmic goître ever develop cancer, and whether, on the other hand, myxœdematous patients display any marked predisposition thereto. We must not forget, however, that cancer has its vagaries. There is the wellknown case of Mr. Gould's, in which a patient apparently dying from cancer, and regarded as past treatment, suddenly took a turn for the better, and ultimately made a perfect recovery treatment of any kind. There are, indeed, plenty of cases on record of the spontaneous subsidence of cancer, and it is hardly in accordance with scientific methods to dismiss all such instances as examples of faulty diagnosis. That is merely begging the question at issue. We must not allow our judgment to be warped by preconceived pathological notions. It is possible, and indeed probable, that the microscope alone does not enable us to establish absolutely the malignancy of a tumour Malignancy, moreover, is essentially a clinical term. it characterises growths in which from microscopical data one would not have expected it, while it is sometimes absent in growths which, as far as microscopical evidence goes, are doomed to rapidly fatal development. These facts should teach us not to be too dogmatic, and not to pin our faith to such a kaleidoscopic science as pathology which, useful when

taken in conjunction with clinical observation, is apt to prove misleading when erected into a scientific dogma. We shall probably not have long to wait for further and more extensive observations on the lines which we have sketched, and these will serve to teach us the limits of the treatment and possibly, later on, the precise method of its action.

THE MEDICAL DEFENCE UNION.

THE annual report for the year 1898, recently issued by the Medical Defence Union, is an interesting docu-It marks the progress of the remarkable spirit of self-help that, in spite of its youth, has sprung up into sturdy and fruitful life within the four walls of the profession. Year by year the roll of members has steadily grown, with a proportionate increase both of income and of the amount of work accomplished. At the end of the year the guarantee fund for emergencies, that is to say available if called up under the articles of association, fell little short of £6,000. At the same time, there was an Accumulated Fund of £755, which represented the surplus of assets over liabilities. important changes have been made in the financial statement of the Honorary Treasurer. Thus, in the balance-sheet, the item "assets" included subscriptions in arrears for the current and preceding years only. At the same time the names of all subscribers more than two years in default have been struck off the register. By adopting this amended form of balance-sheet the Council have been enabled to present figures free of the inflation of worthless arrears. The only feature with regard to the financial side of the work of the union upon which have any suggestion to make is that accumulation of a reserve fund would greatly strengthen the hands of the executive. The younger days of hand-to-mouth existence have now gone by, and the difficulty of saving money should every year be lessened. By the exercise of increased watchfulness and economy an actual reserve fund equal to that now guaranteed might be established, a result that would redound to the credit of the society. In offering this suggestion there is no intention whatever to criticise the management of the Union, which we believe to be carried out with unceasing devotion, integrity and earnest ability. The present membership of the Union amounts to something over four thousand, a small proportion when compared with the qualified practitioners of the United Kingdom, and one that must be greatly increased as the coming generation of medical men wakes up to the necessity and value of professional organisation. Turning to the actual work of the past year we find the usual record of what may be called routine cases, such as those associated with the suppression of unqualified practice and the prosecution of unqualified persons. At the same time there are many cases which have points of special interest. As invariably happens, one result of the prosecutions has been to show the lamentable vagueness of the penal sections of the

Medical Acts. The decision of the magistrates in the case of the unqualified man Matthews, who carried on an extensive practice at Norwich, was that in using the title "Doctor" he had not wilfully and falsely represented himself as a medical practitioner, but for using the description "Surgeon" he was convicted and fined a small penalty. As there can be no appeal against such obviously unfair decisions, it may well be said that the reformer's path is indeed beset with thorns. So again, a jury at Greenwich acquitted a woman who was proved to have dispensed physic and to have advertised a diploma, and in that case as usual leave to appeal was refused. Much more might be said, especially with reference to the purely defensive side of the organisation, but for the present that part of the matter, important as it undoubtedly is, may be passed over with the remark that blackmailing actions for alleged malpraxis, negligence, or other misconduct have materially lessened in numbers since the Defence Union has appeared upon the scene in the character of legal champion. The Union has made a determined effort to bridge over a gap in the Medical Act of 1886 by attempting to enforce a reading of Section 6 to the effect that registered practitioners alone possess the right of carrying on medical practice in its various branches, and to make any trespass upon such right an illegal act. That view was advanced by Mr. Victor Horsley last year. and has since been submitted to expert legal opinion, which has pronounced adversely to Mr. Horsley's contention. For all that, it is to be hoped that a test case may be brought before the Courts, for if the point could be established, it would go far at one step towards doing away with the present deadlock. One important function of the Union has been the collection and recording of evidence of the utmost value to the future regulation of the General Medical Council, and of medical legislation generally. This fact has been emphasised in the case of the conviction during the year of a personator, whose name had been communicated to the General Medical Council by the Union in 1895, but who was nevertheless, allowed subsequently to go upon the Medical Register. It is imperative that the whole of that set of circumstances be fully and openly investigated at the next meeting of the General Medical Council. In conclusion, a word of praise may be bestowed on the Council of the Medical Defence Union, for by their selfsacrificing labours the Association has been advanced to its present sound and vigorous position.

AN OBJECT LESSON IN MUNICIPAL EXTRAVAGANCE.

It cannot be consolatory for the Dublin tax-paying citizens to note that the first act of the newly-constructed Council of their city is to perpetrate one of the most atrocious building jobs of which a municipality ever was guilty. It is right to say that the job was prepared and made safe and snug by the old Corporation, and is simply adopted, in globo, by the new one, which might and should have cast it out with ignominy if it desired to recommend its own zeal

for economy of administration to the citizens. The job consists in the buying up of a filthy slum in the worst part of the city and the building thereon of artisans' dwellings. The slum, itself, is covered mostly with squalid tenement houses, the intrinsic value of which rotten bricks and slates of which are composed, and, if the Corporation had, long ago, done its duty the area would have been declared insanitary, and these houses detenanted, in which case the owners would never have thought the premises worthy of rebuilding or reparation and the whole area would have fallen to the Corporation, as many similar areas in Dublin have done, with insignificant cost. As the matter stands, the citizens are called upon to pay £35,000 for a few hundred cartloads of rubbish, this sum being the amount at which the imagination of an arbitrator and the rapacity of some scores of attorneys assessed the value against the ratepayers. Then come the items of £9,000 for clearing the area. and £47,000 for erecting the artisans' dwellings. That total sum required already exceeds the estimate by £28,000, and we know enough of architects and builders to be confident that, before the transaction is closed, another £10,000 will be added for extras. The whole cost (omitting the last contingent item) is £91,000.

Now, what are the citizens to get in return for this enormous outlay? First, they profit by the extinction of a disgusting slum and the substitution of decent dwellings, but we apprehend that, with a little patience and judgment, this advantage might have been attained without paying any such amount as £35,000 for it. Second, they get 29 houses, each costing £3,137, and the whole containing 210 separate tenements-i.e., £433 per tenement!!! Four hundred and thirty-three pounds for a bricklayer's or a carpenter's lodging-as much as would enable a professional man to accommodate a numerous family in a respectable villa in a fashionable suburb-as much as would build two, if not three, cosy houses for commercial clerks and their belongings in the less popular neighbourhoods! Was there ever such atrocious waste? The Tammany proceedings of the London Metropolitan Board of Works in presence of this job "pale their ineffectual fire."

It will, no doubt, be said that the guardianship of the money of the Dublin citizens is no part of the duty of the Medical Press, but there is a consideration which brings this transaction within the purview of anyone interested in the welfare of the poor. There is a vast population in Dublin of the very poor, infirm, miserable, squalid, and starved who live in cellars and in the worst burrows of the tenement houses and can pay no more for the rent of their lodging than 10d. to 1s. 6d. per week. Obviously it is here that the function of a beneficent Corporation should come in not only out of simple humanity and decency. but to protect the citizens against the dissemination of disease from such holes, and for this the Superintendent Medical Officer of Health and his cophilanthropists have never ceased to clamour.

But these poor creatures have no friends, no votes, and no influence, and are, in fact. not worth a thought from the Corporation, and, as a consequence the Corporation has refused to grant a single shilling for providing them with decent lodging, which could be done for less, per tenement, than one-fourth of the money now being spent on the dwellings of artisans who have votes, friends, and money. Already Dublin is well provided with comfortable dwellings for this artisan class, who can, and do, pay 3s. 6d. to 4s. 6d. per tenement, a rent which returns a decent dividend of 4 per cent. to the speculators in that form of house property. We ask, why should the Dublin Corporation spend the citizens' money in catering for comparatively well-to-do people at a rate of investment greatly below the current in the open market, while it absolutely repudiates its duty to the more necessitous poor which are its natural charge.

Rotes on Current Topics.

School Nominations for the Army Medical Service.

WE understand that the gentleman recommended on the last occasion by the Royal College of Surgeons, Ireland, at the request of the Director General, has been returned on its hands, having been found physically ineligible, this not being the first time that the College has found itself in the same position. While we earnestly sympathise with the gentleman who, from no fault of his own, has been deprived of what he seems to have regarded as a prize within his grasp, we cannot hesitate to express our satisfaction that, as far as the Irish College is concerned the nomination system has again broken down. We have pointed out that the selection of an Army Medical Officer under such circumstances is humiliating to the service, to the officer himself, and to the recommending college, and is injurious to the interests of the Army Medical Officers at large. If the gentleman recommended is satisfied to enter the Service with the record against him of having got in by the back stairs we have nothing to say. We urge upon the Director-General, however, that his going into the highways and byways to gather in the maimed, the halt, the lame, and the blind, is a humiliating confession of the failure of the authorities to attract the best men, and we again urge upon the Universities and Colleges that it is, also, humiliating for them to mix themselves in the personal jobbery which these nominations involve. In our experience the appointment of a Medical Officer to take charge of the soldier has come to be a simple question of the fighting capacity of rival schools and hospitals, and of the personal canvass in the interest of individual candidates. The moment it becomes known that there is a nomination vacancy every tentacle is put out by the rival schools and hospitals to secure the appointment of one of their own students, and every relative of the candidate is put in motion for the canvass. Letters flood the tables of the electors and

touts await them in the streets. No doubt the electing bodies elect a man who will pass muster with the authorities, but, beyond this, the merits of the candidates or the needs of the soldier have little effect on the selection. We insist that such a method of obtaining a Medical Officer is discreditable to all concerned, and, as it seems that the authorities intend to adhere to it, we suggest that the interference of Parliament has become necessary.

Malthusiasism in Ontario.

THE Deputy Registrar-General for Ontario, in calling attention to the low birth-rate of the Province. states that it is due to the practice of Malthusianism. In the year 1897, the birth rate was only 20.9 per 1,000, as compared with a similar rate of 29.2 in the United Kingdon; 38.57 in Quebec; 36.3 in the German Empire; 35.0 in Italy; 38.0 in Austria; and 22.7 in France. In commenting upon these facts, a Canadian contemporary points out that the practice of Malthus among the people of Ontario is no secret to the medical practitioners of the Province, and to have a large family is considered by the Ontario materfamilias as most undesirable. Hence the declension in the birth-rate. The definite assertion, however, by a public official like the Deputy Registrar-General aforesaid, to the effect that the evil of Malthusianism is prevalent in the province, is a most important matter. It draws public attention to a debased practice which reflects seriously upon those accused of practising it. Here is an official who has the boldness to positively point to the evil to which the practice leads, and thus every married woman in the province of Ontario is placed under suspicion of conspiring to avoid her maternal duties by resorting to means to prevent conception. Have the women of Ontario no self-respect, and are they regardless of their moral reputation too?

The Consumption of Tobacco.

THE Chancellor of the Exchequer, to the surprise of the tobacco trade, did not deal with their commodity in his Budget address, save to refer to the satisfactory revenue which the consumption of tobacco yielded to the country. A few facts, however, upon this subject are not without interest. In 1840 tobacco furnished duty to the imperial exchequer to the amount of £3,500,000 per annum, when 22,876,641 lbs. were consumed, as compared with 73.794,197 lbs. last year. The population of the United Kingdom in 1840 was 26,487,026, while now it is roughly 40,000,000. Again, the consumption of tobacco at the earlier date was 0.86 lb. per head, as compared with 1.84 lb. per head now, of the whole population. Thus there is abundant evidence in these figures to show how greatly the consumption of tobacco has increased, per head, in this country, and the question which cannot fail to arise in this connection is, Can such high consumption be regarded as tending to the public good? Within the last few years immense facilities have arisen for the development of the habit of smoking. In London especially large firms have competed with each other to offer tobacco at cheap

rates to the public, and so tempting many to smoke and indulge more freely in the habit than doubtless. in former days, their prudence and means allowed them. This greater cheapness in tobacco has also in a measure been brought about by the reduction in duty of sixpence a pound, introduced by the Chancellor of the Exchequer last year—and possibly this fiscal enterprise was dictated by the idea that in the end it would lead to a greater revenue from one of the most lucrative sources of taxation in the country. However, it is impossible to overlook the contingency that in the course of years the nation will physically not be the gainers by the universal growth in the habit of smoking. Medical men are frequently called upon to treat cases of tobacco toxemia; and "tobacco hearts" are quite a recognised source of illness in the present day. The worst effects of over-smoking are seen in those who lead sedentary lives, and in such even a moderate indulgence in the habit is often productive of baneful results. But the whole subject affords food for curious reflection. The Chancellor of the Exchequer does what he can to make the nation smoke in order that he may have money with which to build warships, while, at the same time, he forgets that he is thus doing a good deal to destroy the "nerves" of those who will be called upon to fight them.

A Lord Chancellor Druggist.

LORD HALSBURY, Lord Chancellor of England, has manifested a determined hostility to the inclusion of chemists in the Companies Act, which, if agreed to by Parliament, would make it impossible for cooperative stores and other such traders to carry on business as dispensers, unless every man behind their counter were a registered chemist. The Chemist and Druggist retorts upon the Lord Chancellor by quoting from the register of shareholders of Lewis and Burrows, Limited, drug stores, the name of "Halsbury, Lord, Peer," as an investor in the company for 100 preference shares. Of course, no one will imagine that his monetary relation to the question could influence Lord Halsbury in the faintest degree, but, perhaps, it would have been wise to silence cavillers by selling his co-operative shares before supporting their system in Parliament.

The Value of High Altitudes in the Treatment of Tuberculosis.

The value of high altitudes in the treatment of tuberculous disorders has been repeatedly shown in the case of human beings, but up to a short time ago no observations had been made or recorded regarding the influence of this treatment upon the lower animals. A work, however, has recently been published in Mexico, giving the results of some inquiries into this point, which are distinctly noteworthy. The authors find that in the lower animals tuberculosis is decreased in high regions. For example, in 1885, out of 73,000 cattle slaughtered in the general abattoir of the City of Mexico, only 45 were tuberculous. Thus it would seem that cattle and men benefit to the same degree when suffering from

tuberculosis by living at a high altitude. tubercle bacillus cannot flourish in a dry, cool atmosphere, such as high altitudes afford.

Object Lessons in Ophthalmia.

AFTER many years of suffering beneath the scourge of ophthalmia the Hanwell Schools of the Central London School District have been released from a burden that at one time was as rife as, say, measles or scarlet fever in an ordinary community. board meeting last week the Medical Officer of the Ophthalmic Isolation Schools, Mr. Sydney Stephenson, was able to report that he had not a single case of ophthalmia from the Hanwell School under his care. Everyone concerned in this desirable result may be congratulated on having furnished a valuable object lesson to the world at large upon the possibility of stamping out ophthalmia. The isolation school is at this moment full of children drawn from other unions, so that there is abundant opportunity for other Boards to go and do likewise. Perhaps these facts may serve to stir up Mr. Chaplin, who promised so much a few years ago. His scheme was handed over to the Metropolitan Asylums Board, and a plot of ground has been bought, but we still await the schools, and an army of Poor-law children in the Metropolis is being inadequately treated and improperly housed. Mr. Stephenson has shown that by isolation and systematic inspection the disease can be rooted out. What more is wanted? or does Mr. Chaplin think his responsibility at an end now that the matter is with the over-worked Asylums Board? One fact brought out in relief in the medical officer's report was that some cases of trachoma, under the most favourable conditions, take four years or more to cure, while the average is two years.

The Lord Chief Justice on Secret Commissions and the Medical Profession.

In a speech at the London Chamber of Commerce, last week, the Lord Chief Justice drew pointed attention to secret commissions in reference to medical practitioners. "Is it not intolerable to be told," he said, "that medical practitioners-I am not attacking the profession as a whole, for these cases are the exceptions-would write a prescription and have a secret arrangement that the chemist shall give them 25 per cent. on the amount of the drugs. Again is it not disgusting to be told as a fact that if a doctor recommends a particular undertaker he gets a slice of the undertaker's business. Anyone who has taken the trouble to look into the matter will know that these are facts_ They are the exceptions-I hope rare exceptionsbut where this moral corruption exists it blunts the sense of honour and honesty." Lord Russell, of Killowen, is not one given to making statements of this nature without being sure of his information. But, however this may be, we should still feel doubtful as to his "facts" unless their authenticity was brought under our personal verification. It is so easy to be led into error in regard thereto. So far as the arrangement with chemists is concerned,

we altogether question whether anything of the kind related exists. Medical men, it is true, are apt to have an understanding with chemists, but this only consists in asking the latter to send them patients, in return for which the chemists have the dispensing of their prescriptions. Again, with regard to the undertakers, Lord Russell's remarks seem more like the revival of a popular erroneous notion than the record of actual "fact." papers devoted to comical matters are disposed occasionally to make laboured attempts to amuse their readers by referring to the supposed liaison between doctors and undertakers. But we have no hesitation in asserting that even Lord Russell would find it impossible to produce a single instance in which such a working arrangement as he suggests between an undertaker and doctor, exists. We are sorry, therefore, that Lord Russell, whose friendly feeling towards the profession is well known, should have expressed himself in the manner which he has done in this matter. He only refers to these cases as exceptions, it is true, but, as will be gathered above, we take exception to the truth even of his exceptions, and, undoubtedly the enunciation of such opinions by the Lord Chief Justice and the London Chamber of Commerce is calculated to convince the public that the secret commission traffic is not exceptionalpersons of such authority should not make such charges without supporting them by cases.

The Registration of Midwives.

This perennial source of controversy has cropped up again, with disgusting regularity, and although, as a legislative measure, the immediate future is not very menacing, the same old arguments are being brought forward orbi et urbe in its favour. It is absolutely necessary that it should be made perfectly clear to the public that the opposition on the part of the medical profession is not based, as alleged, on purely interested motives. It is incontrovertible, on the one hand, that there is great need for a supply of properly trained nurses to attend, it may be, normal labour, and to co-operate with medical practitioners all over the country. Of midwives proper, that is to say, female obstetric practitioners, there is no public need whatsoever, for they could not possibly underbid the fees at which duly qualified medical men are willing to offer their services, while in the matter of skill they must necessarily be hopelessly handicapped. Moreover, if it be deemed that there is really an opening for female obstetricians, the London School of Medicine for Women may be looked to to provide them. It is waste of time to prove that three or six months' perfunctory training cannot convey a trustworthy knowledge of the subject, not even to the extent of recognising an abnormal labour, at any rate until matters have reached a point at which skilled assistance is deprived of much of its value. The gist of the controversy lies in the inopportuneness of the term "midwife." The use of this title implies a diploma which in its turn implies, or should imply, a special training, which is conspicuous by its absence. No one objects to monthly nurses

being trained to their duties, and, if thought desirable, to their being registered, but it is above all things desirable that women with but a smattering of technical knowledge should not be foisted on to the public as capable of replacing qualified medical practitioners.

Cardiac Failure in Medical Men.

How frequently it happens that death overtakes medical men suddenly, generally without warning. Sometimes such deaths are more than tragic. For example, nothing could exceed the tragedy and pathos of the last scene of a man's life, than that of a doctor dying in the sick room of a patient. A case of this nature was recently recorded. The medical man had called to see his patient, and even while feeling her pulse he suddenly fell forward upon her bed, and in a moment he was dead, Within the past few months other instances of similar sudden deaths of medical men have also been published in the Press. There is no doubt that the weakest organ in a medical man's animal economy in the majority of instances is his heart. The wear and tear and strain to which in the course of a busy active practice extending over many years it is subjected, is enormous. At first it may be the strongest organ, but as years pass, it cannot help but fail in strength. oftentimes incessant night work undertaken by the practitioner, what chances has this long suffering organ of recouping itself with much needed rest? And so the time comes when it has simply to admit that it is worn out, and then its brave struggle ceases, and the practitioner dies generally where he stands. With many medical men, perhaps, there is an ardent desire to die in full harness. How could such a wish be more closely gratified than when death overtakes a practitioner at the bedside of a patient?

The Treatment of Neurasthenia.

What is known as the "rest cure" is greatly in vogue in the present day for neurasthenic persons. When life has become a burden from the excessive turmoil of its modern requirements the rest and peace obtained by going to bed and keeping there for a long interval has oftentimes proved to be the best, if not the only treatment for those whose physical capital has all been spent. The "rest cure" is also sometimes applied to horses, that is to say, they are put into pastures for a time and taken from all work with the best possible results. The speed of life in certain occupations to which men devote themselves is far too high to be maintained for any length of time; such is the experience of many in the present day, and it is not until they become the subjects of advanced neurasthenia that they will see the wisdom of curtailing the output of their physical power. Meanwhile the "break-up" of their health is the debt which Nature exacts under such circumstances, and lucky should those consider themselves to be who, by careful treatment, are able to recover from its effects.

Church Bells and Invalids.

THE ringing of the church bell often becomes an intolerable nuisance to the invalid, however readily use may bring tolerance of its noisy jangling to the man who is whole. There is a certain leading hotel in the West-end of London that was separated by the width of a single thoroughfare from a particularly strident church clock. After repeated applications had been made, the local authorities took action and the clock was silenced during the night. Why not? The church clock is not needed in these days of cheap and univeral watches. So with the church bells; it is a useless relic of barbaric ages, when the congregation was scattered and had no clocks and watches, or when danger threatened and the bell summoned folk from far and wide to the shelter of the church. The noisy belfry of to-day is a survival, not only useless, but further, an active offence to the neighbourhood and a danger to the sick. It is only on the rarest occasions that a clergyman has been known to stop the bell-ringing in response to the request of the friends of a sick, or, it may be, a dying man. In the ordinary church the discordant noise is kept within more or less reasonable bounds, but in some sectarian buildings it may be heard intermittently from daybreak to darkness. Why should so useless and, in many ways, objectionable a custom be retained? In some towns, be it remembered, there are half a dozen churches in a single street. Lastly, the bells are often harsh, and jangle out of tune in a way that must spell torture to any invalid within earshot who has the least idea of music.

Another Cancer Organism.

DR. PLIMMER, of St. Mary's Hospital, has come in for a considerable amount of popularity during the last few days in connection with his work on the parasite of cancer, brought before a recent meeting of the Royal Society. He states that he has succeeded in isolating organisms which, he believes, stand in actual relationship to the disease. These organisms possess great vitality, and multiply under conditions which prove fatal to most other pathogenic organisms. They are capable of cultivation by the means in general use in bacteriological work. Inoculated in animals these cultures are followed by the production of cancerous tumours. Judging from the description at our disposal Dr. Plimmer's organisms differ in every essential particular from those of Dr. Bra, whose discovery is now receiving attention on the other side of the Channel, as announced by our French correspondent, the latter being of the nature of a fungus. In spite of many deceptions in respect of this elusive organism, dum spiro spero.

International Congress of Women.

An assembly of those interested in the social and intellectual progress of women is to be held in London from June 26th to July 4th. The discussions in the Congress will be largely devoted to woman's education and work in the medical profession and in nursing.

The Limits of Counter-Prescribing.

THE case of Coleman versus Coldwell and Co. directs attention to the inconvenience and dangers attending counter-prescribing when powerful drugs are dispensed. In this case the mother of the infant plaintiff went to the chemist for a remedy for ringworm, and was given nitrate of mercury ointment. There may have been some misunderstanding as to the way in which this highly caustic pomade was to be used, but in the event violent irritation was set up and permanent disfigurement caused. The jury gave a verdict in favour of the plaintiff for £5, and in so doing they certainly erred on the side of indulgence. It is difficult to deny the chemist the liberty, though not the right, to respond to a request for a cough medicine by prescribing a bottle of some nonpoisonous remedy; but for a chemist to dispense, on his own responsibility, such a powerful escharotic as nitrate of mercury, with or without verbal directions for its use, is a gross abuse; one, moreover, which we should like to see treated with condign punishment. They might as well give atropine or morphia, possibly with less risks of disaster. We trust the lesson will not be thrown away on pharmaceutists whose incursions into the medical domain are likely in future to prove more unremunerative than in the past.

Some Healthy Health Resorts.

THE mortality statistics of certain health resorts for the past year are both interesting and instructive. They show how much can be done for the public health by the adoption by the local authorities of an enlightened policy in regard to sanitation and the enforcement of hygienic principles. The people of Bournemouth will be interested to see that their town heads the list for lowness of mortality. In this popular resort the death-rate last year was only 9.8 per 1,000; Eastbourne comes next, a very close second, with 9.9; Ryde, third, with 10.0. Hove is sixth on the list with 12.4, and Harrogate, eighth with 12.8. Congratulation is justly deserved such towns which can maintain reputation as health resorts in this fashion. Moreover, an example is thus set which the authorities of other localities favoured by Nature should seek to emulate. Capital which is spent in making a health resort above suspicion as to drainage and water supply is money well invested, for visitors in their thousands are largely by this means attracted to the town, and prosperity to the townspeople follows as a matter of course.

A Judicial Farce.

An inquest was held a few days since at Sunderland on the body of a man of 25, who came home feeling ill, and died an hour or two later. A doctor who saw the patient only when he was already moribund, and who said that he had never known that the deceased had anything the matter with him, stated in his evidence that, "taking all things together, he was of opinion that death had resulted from natural causes, most probably phthisis," and the jury said,

judicial farce? No history of illness, and death in a few hours. A doctor, called in to the dying man, without any post-mortem examination declares, "taking all things together," that death is due to phthisis. It is difficult to know on which party to shower one's disapprobation, the doctor who gives that evidence or the coroner who accepts it!

The Promotion of Midwives' Registration.

THE tactics and good taste of the neck-or-nothing promoters of Midwife Registration may be judged from perusal of the following advertisement which they have published in the agony columns of several of the London papers :-

ANTED.—The British Public to know that this beneficent measure will have the effect of reinstating registered women exclusively, and with perfect safety in all cases, &c., &c.

The statement in this advertisement is not true, but, if it were, the publication of it would be equally discreditable. If the opponents of the measure condescend to fight with similar weapons, they could open the eyes of the "British Public" to the spirit which animates the Midwives' Registration enthusiasts.

A Medical Blackleg.

THE union movement promoted by the medical practitioners of county Durham is stated by a local contemporary to have proved "successful beyond the most sanguine hopes of its members," but the Ravensworth Collieries have decided against the claim, and are stated to have secured the services of an experipractitioner, "M.D., L.R.C.P. enced medical L.R.C.S.," for the usual sixpence per fortnigh We regret not being able to give the name of thi gentleman whose "gentlemanly deportment" seems to have enacted such a favourable impression.

Notification of Mercurial Poisoning.

THERE will come into force on May 1st next under the Factory and Workshops Acts, an order to all medical practitioners attending, or called in to visit, any person whom he believes to be suffering from mercurial poisoning contracted in a factory or workshop, to notify the case forthwith, under penalty to the Home Office, and for which he is entitled to a fee of half-a-crown for each such notification. Forms of application will be supplied gratuitously, full particulars of which will be found in our advertising columns.

Ball in Aid of the National Consumption Hospital of Ireland.

An aristocratic and exclusive Ball to provide funds for this hospital will be held on this (Wednesday) evening in the Rotundo, Dublin. Their Excellencies the Lord Lieutenant and Countess Cadogan will be present, and the patronesses include all the aristocracy of Ireland. As the tickets are a guinea each, and the applicants will be narrowly scrutinised, it is not "Hear, hear." Could there be a more lamentable likely that many every-day people will attend.

The Disputed Dundrum (Co. Dublin) Dispensary Election.

WE learn that the Local Government Board for Ireland has intimated its decision that the recent election of Dr. Mackey, of Kilgobbin, to the Dundrum district, vacated by Dr. Usher, is invalid, and that a new election must be held on May 3rd next. It will be recollected that a prolonged inquiry was held respecting the absence of a voter who, it is alleged, was kept away by a bogus telegram. As the full report of the Local Government Board on the subject is not extant, we are unable to judge of the grounds upon which the election has been annulled.

The Royal College of Surgeons, England, and its Assessment Appeal.

The Court of Appeal has dismissed the appeal action brought by the Royal College of Surgeons against the assessment made upon the Lincoln's Inn property of the College, under the Customs and Inland Revenue Act, 1885. The Court held that the Library, like the other buildings of the College, ought not to be exempted from assessment. The sum claimed under the Act is £160 per annum.

Election of Examiners in the Royal College of Surgeons, Ireland.

THE College has issued its notices for the election of Examiner on the first Tuesday in May in all subjects and for all the several Courts. With the exception of the Court in Preliminary Education, which acts in co-operation with the College of Physicians, all examiners must be Fellows of the College.

The New Inebriates' Act.

The first case in which a jury has dealt with an habitual inebriate has occurred at Blackburn. A drunken prisoner, having been convicted for larceny and duly sentenced was then tried as an habitual drunkard and, being again convicted, was sent for three years to an Inebriate asylum.

'SEVERAL children at Douglas (Isle of Man) were poisoned last week by eating hemlock in mistake for watercress, and one, at any rate, has died in consequence. When will our Board School authorities make rural botany a subject of instruction for the young? It is much more desirable that they should be able to distinguish hemlock from watercress than Fiji from Van Diemen's Land.

A DEATH under chloroform was recently inquired into at Liverpool. The victim was a woman, seventy-two years of age, who was undergoing an operation on the eye. The jury agreed to a verdict of "Death from cardiac failure," but we should have liked to know how much, and by what method, chloroform was given. The chances are great that the so-called "open method" has claimed another victim.

PERSONAL.

WE understand that Mr. Mackenzie, recently house surgeon to the Rathdown Hospital, Dublin, has been nominated by the Royal College of Surgeons in Ireland for a Commission in the Army Medical Corps.

Dr. W. MILLIGAN has been appointed honorary aural surgeon to the Royal Manchester Infirmary. Mr. Joseph Collier, F.R.C.S., has been elected honorary assistant surgeon to that institution.

Mr. Jukes de Styrap, one of the best-known practitioners in Shrewsbury and the West, has died at his residence. The College, Shrewsbury, in his eightyfourth year. He was author of "Medical Etiquette."

WE regret to learn, while at press, of the death of Sir William Roberts, M.D., F.R.S. He had been suffering for some time from an internal affection. We hope to publish details of his life and work in our next.

HIS EXCELLENCY SIR WILLIAM MACGREGOB, K.C.M.G. C.B., M.D., is about to leave England to take up his new position as Governor of Lagos. To-morrow. (Thursday) he will address the members of the London Chamber of Commerce on the subject of "British New Guinea."

Scotland.

FROM OUR OWN CORRESPONDENT.

THE INEBRIATES ACT IN SCOTLAND.—The Secretary for Scotland has sent an intimation to the magistrates with reference to the administration of the Inebriates Act, that the Treasury will make a contribution of 16s. weekly in respect of any person convicted of an offence punishable with imprisonment or penal servitude, provided that drunkenness was the cause, or a contributory cause, and the offender is found to be an habitual drunkard, and is accordingly ordered to be detained in a reformatory for inebriates for a period of three years, in addition to or in substitution for, any other offence. A weekly grant of 10s. 6d. will be made in respect of ordinary habitual drunkards ordered to be detained in a reformatory for three years, and a weekly grant of not more than 6d. per diem, at the discretion of the Secretary for Scotland, will be made in respect of each inmate, while out on license for not more than three months. The Treasury will also bear the expenses of the removal of an inmate from one reformatory to another. This scheme of contribution will be in force for three years, dating from April 1st of the present year, and after that date no Treasury grant will be made unless a contribution of not less than 3s. 6d. per week per inmate is made by the local authority. Since receiving the above intimation the Lord Provost has had an interview with the Under Secretary for Scotland regarding the Act, and the Magistrates' Committee have resolved to recommend an inebriate reformatory of moderate size should in the meantime be established, either by the Corporation alone or in conjunction with other authorities.

Town Refuse.—Glasgow Experiment.—Lord Kelvin, and Professor Archibald Barr, of the Glasgow University, have been making experiments on the subject of the profitable destruction of town refuse. One experiment dealt with damp ash-pit refuse, containing a large proportion of night soil and vegetable matter from markets and shops. This, we understand, was consumed without the slightest trace of smoke, and in addition to the solving of the smoke difficulty, the residual products proved to be of great commercial value. In another experiment the steam produced by the process of destruction was utilised for the driving of electric-lighting machinery, and also for other purposes. Neither coal nor coke was used in the experiments. Lord Kelvin in his report shows that public bodies have no longer any excuse for referring to "waste products," but have within their reach the means of turning the most unpromising kinds of refuse to a highly profitable account.

GLASGOW OPHTHALMIC INSTITUTION.—The annual eport of this institution, lately issued, shows that the

Digitized by Google

establishment is in a very flourishing condition, and doing a lot of very useful work. During the year 1898 the out or dispensary patients numbered 12,530, and of this number 692 required special treatment as inpatients, and of these 512 were cured, 168 improved, and 12 were found incapable of further benefit. The average period of residence was 13:1 days, as against 14:79 days in 1897. The number of operations performed on indoor patients was 423, showing an increase of 170 over the previous year. Many valuable and necessary alterations and additions have recently been made in this institution. A new dispensing department has been completed, and through the generosity of Mrs. Elder the large female ward has been provided with new beds and all the necessary furniture and adornments, as also with cots for juvenile patients. At present everything is in a most satisfactory condition, and it is to be hoped that such will continue; but when one institution begins to vie with another and grand displays are made, we become a little anxious, and as onlookers advise caution.

Manchester.

FROM OUR OWN CORRESPONDENT.]

ROYAL INFIRMARY .- Much interest has been excited by the recent election to the honorary staff. As was expected, Dr. Milligan and Mr. Joseph Collier have been appointed, the former as aural surgeon, the latter as assistant surgeon. These gentlemen will be strong additions to the teaching staff. Both hold lectureships at the Owens College. Dr. Fothergill has been appointed to take charge of the new Clinical Laboratory in connection with the hospital. It is probable that further changes in the constitution of the honorary and teaching staff are not far distant

A BIOLOGICAL ASPECT OF CANCER.—Mr. Faraday, at the Manchester Literary and Philosophical Society, suggested that cancer growth might be considered as due to arrested development at what might be termed the crytogamic as distinct from the phanerogramic stage. From analogy it was argued that deficient oxygenation of the blood generally, or deficient local blood-irrigation might account for cancerous proliferation. It was shown that there has been too great a tendency to regard cancer as a case for the surgeon rather than for the physician, and to give attention to the isolation of a pathogenic organism rather than the changes in the environment.

Lamp Explosions.—Mr. William Thomson has pre-

pared a valuable report upon the lamp explosions which have occurred in Manchester and Salford during the last few years. He shows the urgent necessity of raising the legal flash point of petroleum oil, as distinguished from petroleum spirit, to 100 degs. Fahr.

We do not hold ourselves responsible for the opinions of our

THE LISTERIAN RITUAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sir,-In answer to Mr. Bowreman Jessett, I have to say first of all, that it was not I who invented the phrase, "Listerian Ritual," but I adopt it with avidity, it so well describes the whole ridiculous business. It is after the fashion of the ritualists to claim anything and everything that is of use in the treatment of wounds. For Mr Jessett to claim Bantock as a ritualist because he uses sulphurous acid in treating wounds would be as absurd as to claim Lord Lister's own father-in-law, James Syme, as another, because he used sulphate of zinc before Lister was born Dewar, of Kirkaldy, introduced sulphurous acid for the treatment of wounds long before the ritualistic mummery was ever heard of. It is not essential that a man should be branded as a ritualist (in matters ecclesiastic) because he wears a decent white surplice. But the constant changes in the ritualism of Lister makes it certain we can never guess what the next

"Heads I win, tails you lose," of their claims will be. is their double-headed war-cry. aded war-cry. I am, Sir. yours truly, Lawson Tair.

195, Newhall Street, Birmingham. April 13th, 1899.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Mr. Jessett seems to have a peculiar faculty for misunderstanding both my acts and words. I don't know what he means when he says he has seen me syringing out "abscesses in the abdominal cavity caused by stitches. I have never seen such a case. I have had to syringe a suture track, but I have never known one of these communicating with the "abdominal cavity." The reason why I use sulphurous acid in cases of suppuration, is that it is the most efficient cleanser I know, because of its solvent property. If he will try the effect of carbolic acid and sulphurous acid respectively on a mixture of blood and water, he will see that the former turns it milky from coagulation of the fibrin and albumen, while the latter makes a clear solution. This is the reason why I use sulphurous acid and not because of its supposed antiseptic property. Mr. Jessett ought to know by this time that carbolic acid of a strength to kill bacteria will destroy the vitality of the tissues. But I presume it will be impossible to disabuse his mind of an idea which, with him as with so many others, is of the nature of a religion or creed.

I have just received from the Clinical Research Association a report upon a sample of fluid obtained from a drainage tube in a case of ovariotomy with recent parietal adhesions and free oozing. It is as follows:—
"This fluid contains the streptococcus in very small numbers, and the bacillus coli communis." Now, this drainage tube was in for four days and ten hours; it was emptied exactly fifty times, air entering freely with each drawing; the fluid removed (for the most part very bloody) amounted to twenty-three ounces, and at the time of the withdrawal of the tube the temperature was 98.6 degs, and the pulse 86. At the time of operation they were respectively 99 and 104. Does not this show that the presence of these organisms was of no conse-

quence from a pathological point of view?

I am, Sir, yours truly, GEO. GRANVILLE BANTOCK.

12, Granville Place, April 15, 1899.

MEDICAL EXPERTS IN CRIMINAL CASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIE,—The writer of the editorial in your last issue contrasts the French system or medical testimony in Courts of Law with the system adopted in Great Britain. In England each litigant employs his own corps of doctors to swear whatever is likely to prove his own case, while in France the Court employs an expert specialist who is supposed to advise the Court independently of the interests of either litigant. You say the French plan, theoretically at any rate, appears best calculated to secure an impartial opinion by a person of recognised eminence but, in practice, the medico-legal expert but too often follows the lead of the brow-beating juge d'instruction, and strains every nerve to secure a conviction.

My object in writing is to point out that, at the worst the French system is better than ours, and that it could readily be made more perfect by paying the expert as a judge is paid in our country, not by fees, but by a fixed salary, amply sufficient to make him quite independent of the juge d'instruction or anyone else. In our country nothing can be more calculated to mislead justice or to discredit our profession than the system of medical testimony. When a suit for damages—say, for personal injury—commences, each of the rival solicitors looks out for two or three doctors with sufficient repute to "go down" with a jury, sufficient effrontery and readiness to confront a cross-examining counsel, and with consciences of good, leathery, durable quality. The next step is to ensure a partisan opinion on the part of these doctors by putting the desired aspect of the case in the strongest.

way, concealing all the facts favourable to the other side, exaggerating all those favourable to their own side, and, without saying it, making the witness understand that if his testimony is not satisfactory to his employer, that he need never expect another retainer for a future suit from the same source. Needless to say that a medical witness, under such circumstances, enters on the case with a preconceived judgment, examines the patient with the disposition to find out all symptoms conformable to that opinion, and to pass by those antagonistic thereto. One of the worst features of this system is that the result of the suit usually depends on two factors-a, the capacity of the litigant or his speculating attorney to pay a good "bar" of swearing doctors; and, b, the amount of credit which the jury may accord to the opposed medical witnesses. The first of these influences ought not to exist in any court of law, and is supposed not to exist under the French system; the second can have full effect only under our system, and it is it which places the medical profession in the humiliating position which it commonly occupies when shown up in the witness-box. 'The jury, dazed with the mass of totally contrary medical opinion delivered by experts of apparently equal authority, believes neither side, and, after delivering a verdict which is but slightly influenced by the doctor's swearing, goes home and out into society abusing the doctors and discrediting their honesty.

In my opinion justice will never be done in such cases until the opinion of an expert, who is not coached by any side, and who may be regarded as a thoroughly reliable expert adviser, is available for the assistance of the court. If such an expert witness were employed the ruck of swearers and counter-swearers would soon find their occupation gone.

ie. I am, Sir, yours truly, A JURYMAN.

MEDICAL AID ASSOCIATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIE,—The tone of your correspondent's letter in the issue of April 5th is both dignified and reasonable. He protests against the "touting" for clients in general, and against the Medical Aid Societies as representing the forefront of that ethical offence.

How is the evil to be scotched? We may well ask that question, for it cannot and will not be effected by the efforts of those who have to fight the traitor at their own gates. However straightforward, manly and united the general practitioners of a district, they dare not fight the great political and social organisations directly or indirectly connected with the medical aid movements. The friendly societies, again, have thrown down the gauge of cynical defiance to the medical profession. To whom are we to turn for help? Will the General Medical Council come to our aid? I trow not, until we ourselves elect the representatives of our colleges and universities, and get a governing body in sympathy with our wants, wishes and aspirations.

Perhaps your correspondent will tell us who is to "bell the cat." He will find nine-tenths of the profession at his back if he can give us a lead in this important

I am, Sir, yours truly, Another General Practitioner.

Obituary.

DR. WILLIAM FRAZER, OF DUBLIN.

ALTHOUGH the long illness of Dr. Frazer had prepared the public for his demise, yet his death, which occurred on Sunday morning, came as something of a shock to the profession in Dublin. Being born in 1824 he was 75 years of age at his desth, and, during his masculine life of nearly 50 years, he developed many sides to his intellectuality. He was a reliable practising physician, a clear teacher of the subjects upon which he undertook to give instruction, a discreet administrator of the institutions with which he associated himself, and, in addition, one of the most cultured antiquarians,

numismatists, and picture connoiseurs in Ireland. Dr. Frizer died, as many of his cogeners have done, of the sequelæ of influenza. He had served his profession not only as the author of works on the skin and on Materia Medica, and of papers on various subjects which have appeared in The Medical Press and Circular, but as a lecturer on Materia Medica in the Carmichael School, and on Forensic Medicine in the Old Park Street School. He also filled the positions of Fellow, Councillor, and Examiner in the Irish College of Surgeons, besides many other honourable places in other similar bodies.

As an antiquarian Dr. Frazer acquired equal distinction. He had been a Fellow of the Royal Irish Academy for more than thirty years, a member of its Council, and afterwards its Honorary Librarian, in which office he succeeded Sir John Gilbert. He was also a Fellow of the Societies of Antiquaries, both of Ireland and of Scotland. Apart from his scientific pursuits, Dr. Frazer enjoyed respect and friendship for his personal qualities, having always manifested a genial and conciliatory temperament and a suave manner.

Parliamentary Aews.

The Midwives Bill.—Mr. Fulton Egerton moved the second reading of the Midwives Bill, which, he said, was the result of a Select Cemmittee, which sat in 1894 and reported favourably on the subject. It was a subject of immense interest throughout the whole country. The Bill had, he believed, received the acceptance of the medical profession through both the Royal College of Surgeons and the Royal College of Physicians, and had also been favourably received by the United County Councils Corporation. Mr. T. P. O'Connor deprecated discussion at such a late hour, and criticised the provision of the Bill in respect of the training of the proposed midwives. He concluded by moving the adjournment of the debate. but this was rendered unnecessary by the rules of the House, according to which the debate stood adjourned at 5 p.m., after Sir Wm. Priestley had spoken in its favour.

GLYCERINATED CALF LYMPH.—In reply to Sir B. Simeon, the President of the Local Government Board said that the Department was not prepared to supply glycerinated lymph to all qualified medical men on application, though a sufficient quantity was always kept on hand.

LEAD POISONING.—In answer to Sir C. Dilke, Mr. Jesse Collings admitted the death of a man at Hanley from chronic lead poisoning, but added that the non-holding of an inquest was a matter within the discretion of the coroner. He admitted, however, that the fact of an inquiry by the Home Office was not per se a sufficient reason for refusing an inquest, and he reiterated the view that an inquest should be held in all such cases. He explained the circumstances under which the death in question had taken place—delay in precuring and fixing a fan, but gave no hint of any measures against the firm for their negligence.

Medical Rews.

Royal College of Surgeons of England Examinerships.

In our advertising columns will be found the official announcements of forthcoming elections to Examinerships at this college in June next:—

Four examiners in elementary biology, four in anatomy, three in physiology, four in midwifery, and two in public health under the Conjoint Board.

The Council will also elect four examiners in anatomy and four examiners in physiology for the fellowship of the Royal College of Surgeons; and on May 11th next they will proceed to the election from the Fellows of the College of a member of the Court of Examiners in the vacancy occasioned by the expiration of the period of office of Mr. J. McCarthy, who is not a candidate for re-election.

St. Thomas's Hospital Medical School.

THE following scholarships, medals, and prizes have been awarded:—Fifth year's students: Mr. James Gaff, the Treasurer's Gold Medal; Mr. H. J. Horton Smith, the Wainwright Prize; Mr. H. T. D. Acland, the Cheselden Medal. Third year's students: Mr. C. N. Sears, the first College Prize (£20) and the Peacock Scholarships (£38 10s.), second tenure; Mr. A. F. Miskin, the second College Prize (£15). Second year's students: Mr. C. U. Ind, the Musgrove Scholarship (£38 10s.); Mr. W. H. Harwood Jarred, the first College Prize (£20); Mr. J. E. Adams, the second College Prize (£10). (£10). First year's students: Mr. G. C. Adency, the Tite Scholarships (£27 10s.); Mr. C. M. Roberts, the first College Prize (£20); Mr. C. H. Latham, the second College Prize (£10).

Tropical Medicine.

THE King of the Belgians, as Sovereign of the Congo Free State, has contributed £200 towards the establish ment of the London School of Tropical Medicine and the enlargement of the Branch Hospital of the Seamen's Hospital Society. The Archbishop of Canterbury has also contributed £50 to the same object. Lord Lister, president of the Royal Society, is to be the principal guest on the occasion of the inaugural dinner in connection with the Liverpool School for the study of tropical diseases on the 22nd inst. Altogether a sum of 21,700 has been promised towards the expenses of the Liverpool school.

Society for Relief of Widows and Orphans of Medical Men

AT a quarterly court of this Society, held on Wednesday last, Mr. Christopher Heath, vice-president, in the chair, three new members were elected, and the deaths of two reported. The deaths of two widows were announced; one had been in receipt of grants since January, 1870, and had received £1,847 18s., the other since July, 1874, and had received £1,429 10s. A first application was read from a widow for herself and two children, and a grant was made. It was resolved to distribute £1,201 10s. at the next court to the forty-eight widows, twelve orphans, and five recipients from Copeland Fund, now on the funds. Sir Thomas Smith, Bart., was nominated for election as vice-president at the annual general meeting, and the following gentlemen as directors:—Mr. Morley, Mr. King, Mr. Leigh, Mr. Gimson, Dr. Samuel West, and Dr. Whipham. It was decided to hold the annual general meeting on Wednesday, May 31st at 5 p.m. The expenses of the quarter were £56 10s.

Sent to Prison.

MR. ROBERT HERBERT FOOT, of North Brixton, was last week sentenced to three months' imprisonment for gross indecency towards females. The defence was that he was suffering from an infirmity "which often placed him in an embarrassing position," a remark which certainly covered his then position.

Mr. Allinson Again.

"DR." Allinson appeared at the Marylebone Police Court on the 13th inst. to answer charges preferred by the General Medical Council of "wilfully and falsely pretending to be a doctor of medicine and licentiate in medicine and surgery; and, secondly, of using titles and descriptions thereby implying that he was recognised by law as a physician." The magistrate held that the use of the prefix "Dr." conveyed the idea that the defendant was a doctor of medicine and fined him £5, with five guineas costs, but dismissed the second summons.

A Dangerous Nostrum.

On the 11th inst. the adjourned inquest concerning the death of Charles Ellis, who died while undergoing a so-called course of treatment by the Fanyau remedies for epilepsy was resumed. The inquest, as will be remembered, was adjourned for the purpose of having the so-called remedies analysed. The analysis was made by Dr. Campbell Brown, the public analyst, who stated that the medicine was essentially a strong solution of potassium bromide. It appeared that the deceased had taken 150 or more grains of bromide in a cay. That was very excessive. There were other substances of no consequence, the proportions being very trifling. The sym-

ptoms coincided with excessive doses of bromide. D Maule said his opinion was that the bromide had a great deal to do with the cause of death. This opinion was concurred in by Dr. Stanley Bruce Smith, of Liverpool. The jury returned a verdict that deceased came by his death from coma, accelerated by an overdose of bromide of potassium sold and administered by Oscar Fanyau and Company, and they made a presentment that Oscar Fanyau and Company ought not to be permitted to sell that drug under the guise of a fit remedy, and strongly condemned them for the false statements contained in their pamphlets and letters. They considered that the Legislature ought to interfere for the protection of the public against the publication of such false statements, and to prevent the sale of that drug under conditions so dangerous to life. The Coroner added that until the jury was informed by him of the legal difficulties in the way they wished to return a verdict of manslaughter against Oscar Fanyau and Co., and if they came before him again it was probable they would be sent for trial.

PASS LISTS.

Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh, and Faculty of Physicians and Surgeons, Glasgow.

The quarterly examinations in Edinburgh, were concluded on 11th inst., with the following results:

The quarterly examinations in Edinburgh, were concluded on 11th inst., with the following results:

First Examination, Four Years' Course.—Of 8 candidates the following 4 passed:—Robert E. Turner, Nigel Oliphant, Ernest Saxton, and Frederick C. H. Dady.

First Examination, Five Years' Course.—Of 20 candidates the following 9 passed:—Edward H. Knowles, Gideon H. van Zyl, Herbert F. Walker, Charles S. Macaskie (with distinction), George L. Baker, Albert H. Griffith, Henry Carlaw, Reginald N. Macdonald, and James H. Stewart (with distinction).

Second Examination. Four Years' Course.—Of nine candidates, the following three passed:—Robert B. Sandiford, James C. Franklin, and Arthur J. Morkill.

Second Examination. Five Years' Course.—Of twenty-seven candidates, the following seventeen passed:—Catharine F. M. Leach (with distinction), William S. Cowen (with distinction), John B. Mason, Lewis Beesly. Topal C. Ghose (with distinction), Basanta K. Chatterjee, Jeanie Newton, Arthur T. Hoskins (with distinction), Harry F. Wilkin (with distinction), Philip G. Marshall, Herbert E. J. Batty, John D. J. Bruce, Alexander W. Frew, William E. Graves, Alfred L. White (with distinction), Robert H. Cromble, and Henry E. Staniforth.

Third Examination. Five Years' Course.—Of twenty-two candidates, the following fifteen passed:—Henry E. C. K. Murray; (with distinction). David Mitchell (with distinction). Alexander Brownlee, George H. Usmar, William A. O., Cole, David L. Williams, Ernest Hill, William M. Browne, Lionel R. Popham, Ernest F. Cox, Ewen MacKenzie, Gerald S. Coghlan, Thomas R. Leohard, Ezra Khamis, and Dudley Jeaffreson.

Final Examination.—Of 65 candidates the following 30 passed, and were admitted L.R.C.P., L.R.C.S.E. and L.F.P. and S.G.:—William C. Carnegie, Herbert H. E. Russell, Elle P. Marett, George W. Paule, James E. Ratcliffe, William Carey, Reginald F. N. Overton, William M. Paul, Katharine C. Sampson, William A. Pitt, Isaac Daniels, Lawrence W. Cock, Cuthbert L. Dunn, Frederick C. Ackland, Charles A. Festins, W

Aberdeen University.

At the Graduation Ceremony on April 7th, the following degrees were conferred :-

ing degrees were conferred:

Degree of Doctor of Medicine (M.D.):

--*William Findlay, M.A., M.B., of Aberdeen; George Alex. Reid, M.B., Royal Victoria Hospital, Bournemouth; George Savage, M.B., Beverley, Yorks: Aaron M. Sims, M.B., of Sparkbrook, Birmingham; and Robert B. Tydd Stephenson, M.B., Berbice, British Guiana.

*Thesis considered worthy of "Commendation."

Degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.) (Old Ordinances):

--Robert Batchan, A. Ruthwell; Leonard Cotterill, Weybridge: Alexander B. Cruikshank, Aberdeen; John Halley, Aberdeen; Donald F. Mackenzie, Muir of Ord, Ross; Richard N. Petrie, Alford, Aberdeen; Alex. C. Profeit, Dinnet; and J. Sebastian de Silva, Moratuwa, Ceylon.

Degrees of Bachelor of Medicine, M.B., and Bachelor of Surgery, Ch.B., New Ordinances.

Alex. H. Cran, M.A., Nigg. Ross; James M. Duncan, M.A., Aberdeen; Cecil V. M. E. Fanu, Cassel, Germany; aGeorge A. Finlayson, Aberdeen; John C. Galloway, Oyne, Aberdeen; Arthur N. Haig, Ahmednagar. India: Charles Hunter Badenscoth, Aberdeen; Francis A. Innes, Skene, Aberdeen; John McPherson, Aberdeen; George A. Mavor, Aberdeen; John McPherson, Aberdeen; George A. Mavor, Aberdeen; Alex. M. Mitchell, Insch, Aberdeen; Charles Murray, Aberdeen; Alex. Bruce Simpson, Alford, Aberdeen; Charles Murray, William E. Taylor. Aberdeen; James A. Tolmie. Glenglassaugh Banffs; and John H. Wilson, Aberdeen. "With Credit."

Aotices to Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves " Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.-Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before the type is

HOMEOPATHY.

TAKE a little rum, the less you take the better; Pour it in the lakes of Wener or of Wetter.

Dip a spoonful out, and mind you don't get groggy; Pour it in the lake of Winipisiogee.

Stir the mixture well lest it prove it inferior; Then put a half drop into Lake Superior.

Every other day take a drop in water;
You'll be better soon - or at least you enghter.

Iri-State Medical Journal.

Aggrieved.—We cannot insert the communication forwarded by our correspondent. The matter is entirely and solely a personal one, and as such its publication could not serve any useful purpose.

The Treatment of Acne —A Query.

I. E. M. writes: "I have a poor patient suffering from acne rosacea. He is a bootmaker, and cannot afford the time to attend a hospital. I have tried all the usual remedies without avail, and I would be much indebted if some specialist in dermatology would suggest some means of cure."

Dr. J. L.—Apply to the Secretary of the College, Lincoln's Inn Fields, W.C.

STUDENT.—The facts are of considerable interest. At the present time nearly 200,000 species of plants are known to science. Hippocrates was only able to enumerate 234 specimens, but then, of course, he lived as long as 500-400 B.C., which is something more than a "mere detail."

than a "mere detail."

"Questron."—The appointment of additional inspectors under the Irish Local Government Board, to undertake the supervision the Irish Local Government Board, to undertake the supervision of workhouses under the new system, has been long talked of and is much needed, but nothing has yet been done, and we have no reason to suppose that there is any immediate intention of making such appointments. We are, however, aware that vigorous wire-pulling has been going on for months past in favour of certain candidates, and it is quite possible that the pusiness is being kept close, and that appointments may be made at a moment's notice at any time.

any time.

ABSIT OMEN.—We believe the risk of live burial to be chimerical, but the dread thereof sometimes assumes the dimensions of a malady. It is unnecessary to insist on a post-mortem examination which, effectual enough, to be sure, in its purpose, is in many respects objectionable, It would suffice to leave instructions for the electro-contractility of the muscles to be tested before proceeding to interment. An absolute lack of response to electrical stimulation is a thoroughly trustworthy sign of death.

A WORD TO THE WISE.—Apropos of our present agitation regarding the teaching of physiology in the schools, the following from the Medical Natus is worthy of note:—"A school teacher at Port Allegheny, N.Y., the other day received the following note: 'My boy tells me that when I trink beer der overcoat vrom my stummack gets too thick. Please be so kind and don't interfere in my family affairs.'"

Meetings of the Societies and Tectures.

WEDNESDAY, APRIL 19TH.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.). -8 p.m.

Epidemological Society of London (1) Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper:—Dr. F. R. Blaxall: The

Relations of Bacteriology to Epidemiology. (The date April 14th was inadvertently printed on the Sessional Card.)

Bacancies.

County Asylum, Rainhill, near Liverpool,—Assistant Medical Officer, unmarried. Salary commences at £100 per annum, with prospect of increase to £250, with furnished apartments, board, attendance, and washing.

Darlington Hospital and Dispensary.—House Surgeon, unmarried. Salary £140 per annum, with rooms in the institution, but applicant to board himself.

Fisherton Asylum.—Assistant Medical Officer. Salary commencing at £100 per annum, with board, lodging, and washing. Apply to Dr. Finch, The Asylum, Salisbury.

Lewes Dispensary and Infirmary and Victoria Hospital, Lewes.—Resident Medical Officer. Salary £20 per annum, furnished apartments, board, coals, gas, and attendance.

Liverpool Dispensaries, 34, Moorfields, Liverpool.—Assistant Surgeon, unmarried. Salary £30 for the first year, and £90 afterwards, with board and residence.

Manchester, Choriton-upon-Medlock Dispensary.—Resident House Surgeon. Salary £120 a year, with furnished rooms and attendance.

ance Rotherham Hospital and Dispensary.—House Surgeon for three

years. Salary 100 guineas, with rooms, commons, and washing. Also Assistant House Surgeon. Salary £30 per annum, with rooms and washing.

rooms and washing.

Royal College of Surgeons of England, London.—Various Examinerships on the Court (see Advt.).

Stockport Infirmary.—Assistant House and Visiting Surgeon. Salary £70 per annum, with board, washing, and residence. Also Junior Assistant House Surgeon. Salary £2 per mensem, with board, washing, and residence.

Victoria Hospital for Children, Queen's Road, Chelsea, 8 W., and the Victoria Convalescent Home, Broadstairs.—House Physician for six months. Honorarium at the rate of £50 per annum, with board and lodging in the Hospital.

Appointments.

CHALMERS, A. K., M.D.Glasg., D.P.H Camb., Medical Officer of Health by the Glasgow Town Council.

COLLIER, JOSEPH, M.B., B.S.Lond., F.E.C.S., Honorary Assistant Surgeon to the Royal Infirmary. Manchester.

GAYLOB, EDWARD, L.B.C.P.Edim, L.F.P.S.Glasg., Medical Superintendent at the Belper Joint District Isolation Hospital.

HILL, CHARLES A., M.B., B.C., B.A.Cantab., M.B.C.S., Assistant Bacteriologist to the Royal Commission on Sewage Disposal, JONES, HUGH EDWARD, M.E.C.S., L.R.C.P., Honorary Surgeon to the Liverpool Eye and Ear Infirmary.

MCELLIGOTT, MAURICE G., D.P.H., L.R.C.P., and S., Deputy Medical Superintendent at the Belper Joint District Isolation Hospital. Hospital.

Medical Superintendent at the Beiper Joint District Isolation Hospital.

MacGregor, P., L.R.C.P., F.R.C.S.Edin., Honorary Surgeon to the Huddersfield Infirmary.

McMaron, F. D. Sutherland, L.R.C.P. and S.Ed, Medical Officer of the St. Columb Major Bural District Council.

Marin, B. C., M.B.C.S., L.B.C.P., Junior House Surgeon to the Great Northern Central Hospital, Holloway, London.

Milligar, William, M.D., Honorary Aural Surgeon to the Royal Infirmary, Manchester.

Monsarrat, Keith W., F.R.C.S.Eng., Assistant Surgeon to the Children's Infirmary, Liverpool.

Moore, H. C., M.R.C.S., Medical Officer of Health by the Hereford Town Council.

Parker, George, M.A., M.D.Cantab., M.R.C.S., Joint Lecturer on Medical Jurisprudence at University College, Bristol.

Rust, Montague, L.R.C.P., L.R.C.S.Edin., Assistant House Surgeon to the Glasgow Bye Infirmary.

Willoughey, W. G., M.D. Lond., D.P.H.Camb., M.R.C.S., L.R.C.P., Medical Officer of Health to the Borough of Eastbourne.

Births.

Bowie.—April 13th, at 40, Hertford Street, Muyfair, London, W., the wife of Dr. Alex. Bowie, of a daughter (premature). NewBolr.—On April 12th, at 42, Catharine Street, Liverpool, the wife of George P. Newbolt, M.B. Durh., F.R.C.S., of a daughter.

Marriages.

CORNER - MACKWOOD. —On April 12th, at St. Martin's, Trafalgar Square, London, Frank Corner, M.R.C.S., L.R.C.P., F.G.S., son of F. M. Corner, J.P., Poplar, to Elsie Tatham, only daughter of Thomas Watson Mackwood, and grand-daughter of the late Christopher Tatham, M.R.C.S.
GRIFFITH—JONES.—On April 12th, at St. Mary's Church, Dolgelley, Harry Rathbone Griffith, M.D., Portmadoc, to Mary Elizabeth Amoyl, youngest daughter of Dr. John E. Jones, J.P. and D.L., of Bryn.y-Fynon, Dolgelley.
MILLEN—WILLS.—On April 13th, at the Parish Church of St. Michael, Sittingbourne, Seymour A. Millen, M.R.C.S.Eng., L.R.C.P.Lond., eldest son of Alfred Millen, of Sittingbourne, to Mary R. Wills, only daughter of Daniel Wills, of Sittingbourne.

Beaths.

LANPHIER.—On April 12th, at Alford, Lincolnshire, Charles William Lanphier, M.R.C.S., L.R.C.S., aged 28.
ROBERTS. On April 16th, at his residence, 8, Manchester Square, London, Sir Wm. Roberts, M.D., F.R.S., in the 70th year of his age.

his age.

Bowlands.—On April 10th, at King Street, Carmarthen, James Rowlands, F.E.C.S., in his 55th year.

PEPSENCIA.

PEPSENCIA is an ever-ready digestive fluid, containing all the soluble constituents of the gastric juice, preserved in an agreeable aromatic menstruum. It represents both the peptic and milk curdling ferments obtained directly from the fresh peptic glands.

PEPSENCIA is acceptable to the most delicate and fastidious patient, while it excels all other allied preparations in activity and utility.

One teaspoonful before or after a meal will be found of service in all cases where pepsin is indicated.

Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1s. 9d. and 3s. each.

Peptogenic Milk Powder.

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1s. 9d. and 3s. 4d. each.

Specimens and literature will be forwarded on request.

Originated and Manufactured by

THE BEST TO-DAY.

" 17th June, 1895.

" DEAR SIRS,-

"I have used your preparation 'Nepenthe' for a number of years in cases of insomnia connected with insanity, and have always found it above all other anodynes the 'King of Narcotics.' I don't think I should be doing you justice if I did not report to you on its marvellous efficacy. I have found it always produce hours of peaceful sleep, and to be unattended by any bad results. Patients suffering from melancholia with accompanying insomnia under my care have taken it every night for years without one bad symptom. I never find thirst, dryness of the tongue, or constipation, result from its use, and I view it as the most valuable remedy we possess for allaying brain irritation, and producing peaceful and healthy sleep. I have thoroughly tested all the various remedies usually given for the relief of some of the troublesome phases of mental disease, and can safely say that none are so good or reliable as 'Nepenthe.' It has all the good properties of opium without any of its drawbacks.

"I am, dear Sirs,

"Yours truly,

"L.R.C.S.Edin., L.M., L.S.A., &c., "Mem. Med. Psycholog. Assoc.

DEATHS AFTER ABDOMINAL CŒLΙΟΤΟΜΥ. (α)

By W. J. SMYLY, M.D.,

Gynæcologist to the Adelaide Hospital, Dublin.

Thoughthe views I hold are shared by the majority of operators at the present time, and may, therefore, seem trite and lacking in originality. yet so rapid have been the advances in abdominal surgery in recent years that I think the Council of the British Gynecological Society have acted wisely on this occasion in calling a halt in order that we may see how far it is possible to fall into line, and that we may count the cost of our operative procedures. And as regards the causes of death after abdominal operations, I know that there is among the Fellows of this Society a sufficient divergency of views to render the discussion of the subject both interesting and instructive. To some fatalities after colliotomy are attributed almost exclusively to the invasion of the peritoneum by micro-organisms; whilst to others this is of secondary importance, and to others again of no importance at all; so that the subject cannot be regarded as closed to discussion, and, remembering that a majority, however great, is not necessarily in the right, we should put aside partisan feeling, and approach the discussion with a simple desire to know

Among the causes of death after collotomy more or less due to abdominal conditions are:—

Shock.
 Hæmorrhage.
 Ileus.
 Uræmia.
 Inanition.
 Tetanus.
 Embolism.
 Sepsis.

SHOCK.—Though we are familiar with the symptoms it is difficult to define the nature of this condition, to say that it is "a profound impression made on the nerve centres and indicating extreme depression of the patient's vital forces" is rather vague, whilst the statement that "it is due to exhaustion of the medulla oblongata and spinal cord leading to a great reduction in the vital activity generally, and resulting from severe irritation of the peripheral ends of the sensory and sympathetic nerves," is in the present state of our knowledge too precise, nor does it include all the cases which present a common group of symptoms, but in some of which there has been no marked or prolonged nerve irritation, as, for example, those resulting from anæsthesia, hæmorrhage; or one recorded by Fritsch, where an ovary was removed in five minutes, and yet for hours afterwards the patient remained in an alarming condition of the profoundest shock. It appears then that the term shock applies to a group of symptoms which may be due to a variety of causes, but is generally in direct proportion to the magnitude and duration of the operation, especially when associated with long exposure and manipulation of the intestines, to the amount of blood lost, and

the cooling of the body generally. Patients already debilitated by disease, such as cancer, bleeding myomata, and granular kidneys, bear operations badly, and also those with "weak hearts." Not so much valvular disease as what is commonly understood by this term, namely, hearts with rapid and weak action, whether this be due to imperfect development, degeneration of tissue, previous illness, or nervous excitement. Failure of the heart is one of the most prominent features in shock, and it is a matter of common experience that women who accept their position with quiet resignation are less affected by it than those of a nervous temperament, and that where anxious days and sleepless nights have preceded an operation, the heart, worn out by nervous palpitation, fails to meet the extra demand which may be made upon it. Not only may this cardiac insufficiency prove directly fatal, but it may, as pointed out by Fritsch, do so indirectly; for not the circulation of the blood only but also the movement of all the fluids in the body, depends upon the heart's action. If the heart be strong, or if it soon recovers after operation, the circulation of the blood and the flow of lymph continue normal; as also the currents in the peritoneal cavity, where absorption takes place with extraordinary rapidity; lymph, blood, and micro-organisms are carried away through the lymphatics into the circulation, where the latter are rapidly destroyed or rendered harmless by the blood, Nature's great antiseptic. But for this to occur three things are necessary: first, there must not be too many cocci; secondly, there must be a sound heart; and an undisturbed circulation; and, thirdly, the functions of the peritoneum must be normal. Where the heart is weak, and continues so, the flow of lymph is impeded, peritoneal absorption is diminished, or ceases altogether, and a fluid collects in its cavity forming a stagnant culture medium eminently suitable for the development of germs, which are seldom altogether absent even after the most aseptically conducted operation. There exist, then, a number of peripheral dangers which a strong heart could overcome, but which with a weak heart may prove fatal. Not only do the causes already mentioned cause depression of the heart's action, sluggish circulation, diminished absorption, and suppression of urine, but exposure and manipulation of the intestines is followed by derangement of the physiological functions of the peritoneum. These injurious effects are observable in the congested and disordered circulation, the dilated blood vessels and the reddened and lustreless peritoneum. The muscular and mucous coats participating, peristalsis becomes weak, or ceases altogether; the mucous membrane swells, and ceases to absorb; much flatus forms and is not expelled; there is excessive tension in the intestines, and under such circumstances a passage of their contents into the peritoneal cavity is possible. We know that white blood cells can escape, and in them, with them, and apart from them doubtless intestinal bacteria also.

Fritsch, who has drawn especial attention to this subject, attributes these changes to air contact and pressure changes, rather than to cooling and mechanical injury; though he says they are doubtless aggra-

⁽a) Paper read before the British Gynaecological Society, April 13th, 1899.

vated by rough treatment of the peritoneum with unsuitable materials when the intestines are rubbed and dragged about in performing the peritoneal toilette, or where chemicals are introduced into the

peritoneal cavity.

Walthard, of Bern, however, from a series of experiments on animals, came to the conclusion that the injury was due to the drying qualities of the atmosphere; though he did not deny that it might in some measure be due to its coldness causing contrac-tion of the blood-vessels and imperfect nourishment of the serosa. He, therefore, warned operators against drying the peritoneum, and recommended the use of moist compresses wrung out of sterilised salt solution. Sänger, of Leipzig, adopted these views, and Schiffer, his assistant, reported much better results, especially the earlier return of peristaltic action and expulsion of flatus since the introduction of moist asepsis. Uhlmann, however—assistant to Professor Zweifel in the same city—states in a recent publication that no apparent benefit has resulted from moist asepsis, which is inferior to the dry in other matters, especi-With these latter views I am ally as a hæmostatic. inclined to agree and prefer the dry compresses taken directly from the can in which they have been sterilised, excepting only those which directly cover the intestines, since the latter are liable to adhere to the dry cloths.

These cases present, according to Fritsch, peculiar clinical and post-mortem appearances. The patient awakes from the anæsthetic with a peculiar anxious feeling, embarrassed respiration, and a feeble heart. She complains that the binder is too tight. The intestine is paralysed, tympanites occurs without fever, the tongue is dry, and the pulse is fast, and grows faster and faster. The sensorium remains clear, but the weakness and anxiety increase. On the evening of the second day, or later, fever sets in, the tympany increases, the pulse grows thready, and the patient dies.

This, he contends, differs from sepsis, because an acute septic condition could not develop within an hour of the operation. Fever sets in early in sepsis, late in these cases, and the fact that one patient may die in this way, whilst others operated upon the same day make good recoveries, proves that no serious error in asepsis has been made. There are peritoneal symptoms no doubt, but not peritonitis, since there is neither fever nor tenderness, and these cases often recover, whereas the acutely septic invariably die. Such patients become septic towards the end, but cardiac weakness is the prominent symptom throughout; and they die not because they are septic, but they become septic because they are dying.

The better results obtained by vaginal methods he believes to be due to the peritoneum retaining its physiological functions, which are not altered by contact with the air, cooling, or pressure changes; and he holds that the excellent results obtained by Lawson Tait, Bantock, Koeberle, and others are due to rapid and careful operating, whereby central and peripheral injuries are so slight that the functions of the heart and peritoneum are little interfered with.

It may, perhaps, be wrong to consider hæmorrhage in connection with shock, but there can be no doubt that a large number, if not the larger number, of cases reported as deaths from shock have been due to loss of blood during or subsequent to operation. Hæmorrhage after operation may be due to the slipping of a ligature which has been improperly is, applied, from denuded surfaces, or torn adhesions, of omental vessels, or from puncture of an epigastric artery, when inserting the abdominal sutures. The spouting of a large vessel soon gives rise to symptoms easily recognised, but a small oozing is more easily recognised. It occasionally happens that owing to

heart failure the bleeding ceases altogether, or appears so insignificant that the abdomen is closed; but after the patient has been put to bed and warmth and stimulants employed, with the recovery of the circulation the bæmorrhage returns, and its symptoms may be confounded with those of shock.

Zweifel has laid particular emphasis upon the importance of absolutely checking all oozing before closing the abdomen, especially where much loss has occurred during an operation. After severe hæmorrhage, he says, the heart works with half-filled vessels, the demands upon it are increased, and it works with great rapidity. If the bleeding point has been secured and the circulation enclosed within itself it gradually refills; all the organs and tissues pouring serum into it. The functions are gradually restored, the patient comes round by degrees and

climbs step by step back to life.

But if, on the other hand, even a small hæmorrhage goes on it works against the heart's action both dynamically and reflexly. When the latter improves the hæmorrhage increases; as more serum flows into the circulation the blood becomes more watery, less cosgulable, and thus less adapted to the spontaneous closure of the bleeding vessels. The heart working with a half-filled circulation aggravated by even a small continued loss he likens to a steam engine working a ship's propeller, which lifts out of the water, or a locomotive when the wheels slip upon the rails. The mechanism is imperfect, having lost its accustomed grip, it resembles a pump insufficiently supplied with water. It is, in fact an empty pumping heart which authors term shock.

Late or secondary shock has been described, but I have never met with an example, and am inclined to attribute the fatal issue in cases that I have seen recorded to secondary hæmorrhage, sepsis, or the giving way of sutured viscera, especially intestine.

Preventive Treatment of Shock.—In weak and debilitated patients with weak hearts and rapid pulse operation should be if possible postponed or abandoned. The operation room should be heated to 75 or 80 degs. F., prolonged exposure of the surface of the body but especially of the intestines, should be carefully guarded against. The loss of blood should be reduced to a minimum, and the first symptoms of depression carefully watched for and actively treated.

Treatment of Shock-I think we are pretty well agreed as to the main lines of treatment in these cases Hæmorrhage should at once be controlled, and where the loss has been considerable, sterilised salt solution infused either into the subcutaneous connective tissue or directly into a vein. In my practice in the Rotunda Hospital I formed an unfavourable opinion of the former, and abandoned it in favour of intravenous infusion, but the apparatus of Munchmeyer, which I employed, was imperfect compared with that used by Dr. Howard Kelly in the Johns Hopkins Hospital, by which a large quantity of solution can be more rapidly infused with a fall of six feet, and it is so strongly recommended by him that I am inclined to have recourse to it should the occasion occur. In all cases of shock, whether due to loss of blood or other causes, the patient should be placed in a warm bed between blankets with her head low, heat should be applied by means of hot water bottles, enemata of hot saline solution and stimulants administered. The best enema in such a case is, according to Dr. Kelly, one containing two ounces of brandy, twenty grains of carbonate of ammonia, and hot water or beef tea to eight ounces. At the same time brandy, ether, and strychnine are administered hypodermically. Opinions differ with regard to morphia, but I think its use should be restricted to cases in which pain is an important factor in the nervous depression. Excepting in cases where loss of blood has been considerable, saline infusion is of little value, though in some cases of pro-tracted shock, it might, as Mr. Watson Cheyne has pointed out, prevent coagulation of blood in the pulmonary vessels, a recognised cause of death under such circumstances.

Ileus is one of the greatest disappointments that abdominal surgeon encounters. I have lost two an abdominal surgeon encounters. patients from this cause during the past year, one twelve months and the other six years after opera-The former occurred in England and nothing was done; the other came into hospital on the sixth day after obstruction, too late to save her life. Excluding cases of paralysis due to peritonitis, ileus is generally due to adhesion of intestine to raw surfaces, either the abdominal wound, the stump or pedicle, omentum, or surfaces denuded in enucleating tumours or breaking down adhesions, constriction of bowel by bands or from a coil of intestine slipping through a hole in the omentum, kinking of intestine or volvulus. Cauterised surfaces and those deprived of epithelium by abrasion have been blamed for this accident, but this has been denied by others and it is doubtful whether such injuries would cause adhesion unless deeper structures were destroyed. It has also been stated that septic infection is necessary, but experiments have shown that this is not the case, and that with the most rigid asepsis adhesions as a rule take place. When intestines are long exposed and much manipulated, they undergo changes to which I have already alluded, and adhere together. Walthard found that where the peritoneum had been long exposed the superficial epithelium perished, and an inflammatory demarcation formed between the dead and living tissues. If two surfaces thus affected remained in quiet contact they adhered. If they were not so left fibrous changes only occurred, nor would a surface so affected adhere to a normal one. Sänger, as I have already mentioned, adopted these views, and attributed some cases of fatal ileus to the use of dry asepsis; but Uhlmann states that in a number of cases in which the abdomen had to be opened a second time in Zweifel's clinic they always found adhesions to the wound, to the stump, or to places denuded of peritoneum, but never between coils of intestine that had been exposed to the air, and I think that this will be found to coincide with the experience of most operators. The early diagnosis of this complication is of the utmost importance, but unfortunately this is often impossible. Where the symptoms set in suddenly with violent paroxysmal pain in a localised position, where the peristaltic action of the intestine can be seen and felt through the abdominal wall, and the patient lies prostrated between the attacks bathed in cold perspiration. Where neither flatus nor fæces are expelled after energetic efforts to procure evacuation, where vomiting sets in after the second or third day, and the abdomen becomes distended, an error is scarcely possible, but such a stormy onset is exceptional, and most of these symptoms are simulated by other conditions. The obstruction may even be incomplete, and the bowels may be evacuated at intervals, and yet the patient may be lost. In any case, active measures should be at once employed to induce the bowels to act, the stomach should be washed out, and copious enemata administered with a long tube, and where the stomach can tolerate it calomel, Glauber's, or Epsom Should these salts administered. measures fail, the abdomen should be reopened with-out further loss of time. The earlier the gut is freed the better is the prognosis. As to prophylactic measures, Trendelenburg's position is one of the most important, since the bowels are out of the way and are not disturbed, but especial care must be

taken when the patient is restored to the horizontal in arranging the intestines in their normal position, and seeing that they preserve their natural relation to the omentum. Coating raw surfaces with collodium has been recommended, and Martin of Berlin introduces a sponge soaked in sterilised oil, but most operators attach more importance to drawing down the omentum between the abdominal wound and the intestines, and as far as possible covering all raw surfaces with peritoneum.

Thrombosis occurs from septic infection, or from prolonged pressure of pelvic tumours upon veins, or sluggish circulation due to the quiet recumbent posture or the change in the intraabdominal pressure due to the removal of large tumours. As thrombus is a potential embolism, and as it may be set free even at a late period, patients should be cautioned against violent efforts or straining for some time after an abdominal operation. I lost a patient from this accident during the third week after operation; she had been sitting by the fire talking to the other patients, and was in the act of pulling off her boots when she suddenly was seized with a feeling of suffocation, precordial anxiety, gasping respiration, cyanosis, and died in a few minutes.

Of Tetanus I have had no personal experience.

Peritonitis.—A question of much importance is whether peritonitis is always septic. Many would answer this question in the affirmative, but there is much to be said on the other side. There is a condition called traumatic or plastic peritonitis, it is best marked in cases where the intestines have been long exposed and much manipulated, and where wide areas of adhesion have been separated. In the worst forms of this affection there is vomiting, severe pain in the lower abdomen, tympanites, tenderness on pressure, accelerated pulse, and elevation of temperature. Death may result in such cases from pressure of the distended intestines on the diaphragm or from ileus. The treatment of this condition recommended some years ago by Mr. Lawson Tait, namely, free purgation, is, I believe, at the present time the recognised method. The non-infective character of many of these inflammations has been proved by Dr. Howard Kelly, who, when obliged to reopen the abdomen to relieve obstructed bowel, found extensive union between adjacent peritoneal surfaces, but these cases failed to show any kind of micro-organisms in the peritoneal cavity, and yet the evidences of the pouring out of a plastic lymph with the subsequent formation of adhesions were abundant.

SEPTIC INFECTION.—I now come to septic infection, the most important part of our subject, including the germ theory of disease, yet how can I deal with it in such an assembly as this? What can I add to all that has been already said and written upon the subject? The part played by living organisms in the production of disease has been most firmly established by "many infallible proofs," and appears to me as certain as the law of gravitation or the shape of the earth. I shall not therefore try your patience by repeating the arguments now upon which the germ theory is based, nor shall I describe in detail the various conditions to which the introduction of such organisms to the human body during abdominal operations may give rise. I would rather devote the few remaining moments allowed to me in considering how best their entrance may be prevented, and the effects of such contamination treated.

Some who place their faith in procuring absolutely aseptic conditions spare no pains in attaining this object, whilst others regard such extreme precautions as superfluous, and laugh at those who practice them as extreme ritualists; some even discarding all precautions excepting cleanliness, and attributing their success to perfect technique and skill in operating. For myself, I must confess that I am a ritualist. Since deaths from infection still occasionally occur, we cannot flatter ourselves that we have reached perfection, though even at present such fatalities are more often due to imperfection in carrying out already acquired knowledge than in the lack of reliable information. Most of us have, I imagine, passed from antiseptic to aseptic methods in the treatment of wounds; the former method went too far, in that fresh wounds and healthy peritoneum were treated as if they were septic, whilst on the other hand chemical agents were not absolutely efficient in the prevention of infection. The present aseptic treatment consists essentially in perfect cleanliness, and whatever others may say I have no hesitation in stating that the doctrine of cleanliness originated with and has been based upon the teaching and practice of Lawson Tait and Bantock. Years ago, whilst most of us were practising antiseptic methods, they, in the face of bitter opposition, insisted upon the importance of perfect cleanliness, and pointed out the injurious effects of chemical substances in irritating and poisoning the tissues. And at the present time we differ from them only in the meaning of the word perfect, for, whilst they are satisfied with ordinary cleanliness, we strive after and in a great measure obtain not only macro, but also microscopic, cleanliness. By perfect asepsis, then, we understand that everything which comes in contact with the field of operation must be absolutely pure. Everything includes not only the operator and his assistants, his instruments and dressings, but also the air and water. An operation may be carried out aseptically in any ordinary room, but this is achieved with great difficulty and risk, so that in my opinion so serious a proceeding as coliotomy should, except under peculiar circumstances of emergency, always be performed in a special apartment so constructed that absolute cleanliness can be insured with pure air free from draughts, ample supplies of pure water and good light, and heated to about 80 degs. F. The operating theatre in the Rotunda Hospital is divided into two parts by a glass screen, in the first of which are placed the basins, sinks, instrument cases, sterilisers, and platform for spectators, all of which are indispensable, but would be difficult to clean with sufficient ease and rapidity, especially where several operations have to be performed in succession. Their absence from the inner compartment enables its furniture to be so simple that it can be thoroughly hosed out in a few minutes.

A pure atmosphere, free from draughts and dust, and uncontaminated by spectators, is obtained by its complete isolation, its simplicity of construction, and the cleanliness and dampness of its walls. Whilst the high temperature of the inner compartment enables us to dispense with blankets, maintains the patient's vitality, lessens shock, and dissipates mist, the outer compartment is so cool that the spectators, though dressed in their ordinary clothing, suffer no inconvenience.

Lastly, it enables the spectators to approach close to the operation without any risk of disturbing the operator or meddling with his arrangements.

Where an operation has been carried out with thorough aseptic detail and hæmorrhage completely arrested, drainage, one of the most important aids to success in former times, is now but rarely needed, but can never, I fear, be entirely abandoned.

With regard to the after-treatment of septic cases, I shall only state that I place most reliance upon alcohol; of antistreptococcic serum I have had but little experience, and that of a not very favourable

kind. The reopening of the abdomen and thorough washing of the cavity I view in a pessimistic manner, though Howard Kelly speaks of it with approbation. The chief difficulty is diagnosis, for when this is clear it is generally too late to interfere.

In conclusion, I may epitomise these somewhat fragmentary remarks with the advice of Doyen,

Operer vite et bien.

NOTES ON

FOUR CASES OF INTUSSUSCEPTION.

By ALBERT E. MORISON, M.B., F.R.C.S., Hon. Surgeon Hartlepools Hospital.

Case I.—M. R., set. 3 months. First seen January 21st, on account of intermittent attacks of crying, accompanied by diarrhosa. Duration, four hours.

History.-The patient had been apparently perfectly well all day. Immediately after her evening bath she began to screech as if in pain, and to draw her legs up. These symptoms continued more or less constant for two hours, when diarrhœa set in. The stools, at first natural, soon became mucoid and tinged with blood. I was sent for about 11 p.m. The child had always been difficult to feed, owing to gastric catarrh, and its mother's milk was so scanty that artificial substitutes had to be resorted to. The bowels had been constipated since birth. I found the infant lying in a restless sleep on its mother's knee. It was roused at intervals of ten or fifteen minutes apparently by griping pain in the bowels. The paroxysm was ushered in by a shriek. The legs were drawn up and the child writhed about in agony. At the same time the bowels acted. Sickness was also frequent. There was nothing abnormal to be seen on inspecting the abdomen. On palpation the abdo-minal walls were tense, and there seemed to be some tenderness on pressure, but nothing abnormal could be detected. Per rectum nothing could be felt. As the symptoms all pointed to intussusception the usual method of large injections was tried, but without any apparent good result. Although warned of the serious nature of the case, the parents would not listen to my suggestion that an operation was necessary. Small doses of morphia were accordingly given to allay the pain.

The child continued in much the same condition during the next week. Though the morphia, which had been given regularly, somewhat masked its symptoms. Sickness continued; diarrhea was not so frequent as at first, nor the evacuations so profuse, and the blood had disappeared from them. The condition of the child steadily deteriorated, and it grew manifestly thinner. On the fifth day a sausage-shaped mass could be felt along the course of the ascending colon. During the second week the symptoms remained much the same, except that the sickness was less frequent. Emaciation still progressed, and it seemed hardly possible that the child could live much longer.

On February 6th the child passed per rectum a mass of intestine twelve inches long. From this date improvement commenced, and the child began to regain its former condition of nutrition. Now, some years after, she is a strong and healthy girl.

CASE II.—F. D., æt. 11 months. According to the mother's statement, she had been vomiting constantly for ten days.

History.—On June 27th, the patient was being carried by her sister, who let her fall. On the following morning (28th) the present illness began with violent vomiting and screeching. In a short time she passed per rectum a large quantity of blood. She

had been under medical care, but the sickness had still continued, and there was a constant discharge from the rectum of dark treacly fluid. On July 8th I saw the child. She was very much

wasted, with pinched face, distended and tympanitic abdomen. The vomiting was incessant, and a dark thick fluid was constantly passing from the bowels. On palpation a sausage-shaped swelling could be felt in the area of the descending colon, and per rectum a mass could be felt extending down to within an inch of the anus. The child was so ill that any operative procedure was out of the question and it died in a few hours.

Post-mortem Examination.—On opening the abdomen gas escaped. The peritoneal cavity was flooded with intestinal contents and the swelling, previously felt, was seen. It consisted of an intussusception of the ileum through the ileo-cæcal valve. This had been forced in through the ascending into the transverse and descending portion of the colon, sigmoid flexure and rectum. At the splenic flexure the intussuscipiens had been perforated and the mucous membrane of the ascending colon projected through the opening. The invaginated small intestine reached to within an inch of the anal orifice.

CASE III.-C. R., æt. 3. First seen March 12th, 1895, complaining of severe intermittent pain in the abdomen, and diarrhea of twenty-four hours'

History.—Up to the evening of the 10th, the patient was perfectly well, when his mother, thinking he had a commencing cold, gave him a dose of castor oil (3ij). On the morning of the 11th, he was seized with very severe pains in the abdomen, accompanied by diarrhea and sickness. These symptoms continued during the day and until the following morning. The motions then became mucoid and contained a considerable quantity of blood. He had always been a healthy child with entire freedom from digestive troubles.

When I saw him on the 12th, he was looking very careworn. He lay in bed, passing from him every few minutes mucus tinged with blood. The evacuation was preceded by slight pain, and followed by tenesmus. He had not been sick for twelve hours.

Inspection. The abdomen was to all appearances normal. It was quite flaccid on palpation, and along the left side in the line of the descending colon could be felt a mass of an elongated sausage-shape, extending from the costal margin to the left iliac fossa. The swelling was slightly tender to touch. On rectal examination the anus was patulous, and my finger introduced high up could feel the tip of something resembling a soft cervix and os uteri, round which it could be freely passed. Chloroform was at once given, and a large enemata employed with the object of reducing the intussuscepted bowel. These failed, and the colon was next dilated with air, but this also produced no improvement. Immediate surgical interference was then advised, but before deciding the parents requested a consultation, which was held the same evening. A continuance of large enemata administered under chloroform was advised by the consultant. These were repeatedly tried the same night and following day, but without any satisfactory result. Tenesmus and diarrhea still continued, and though the child was taking and retaining a large quantity of nourishment, it was manifestly getting weaker. The tip of the intussusception could now be felt within an inch of the anus. Not till the morning of the 14th did the parents consent to operation, which was performed at 11 a.m.

Operation.—An incision, three inches long, was made in the left linea semilunaris, directly over the thickened colon. On opening the abdomen the descending colon was at once found, and on tracing it upwards it was seen that the splenic flexure had

become invaginated into it. By grasping the intus-suscipiens close to the neck and kneading the lower portion of the intussusception upwards the former was easily dislodged. There were no adhesions, The abdominal wound was rapidly closed, and the little patient put back to bed in twenty minutes, having suffered very little from the operation.

During the day the patient was wonderfully well. It took nourishment freely. No diarrhœa, had passed flatus, and had very little pain. A $\frac{1}{12}$ gr. morphia

suppository was given.

10 p.m.—Patient rather drowsy. Temp. 100 2.

Pulse 120. No sickness or diarrhea. Taking nourishment well.

15th, 4 a.m.—Called up to find patient dying. Has had no obstructive symptoms, and is evidently dying of some form of toxemia. Temp. 1026. Pulse almost absent. Died half an hour later.

CASE IV .- D. S., æt. 5. First seen April 28th, at 10.30 a.m. Complains of severe paroxysmal pains in the bowels, accompanied by diarrhosa, of 21 hours' duration.

History.—Patient went to bed on the evening of the 27th, apparently perfectly well, after having par-taken rather freely of oranges during the afternoon. He slept well till 6 a.m., when he awoke, and was very restless. At 8 a.m. his bowels were abundantly moved, the stool being well formed, but containing much undigested food. He was immediately afterwards seized with a very severe pain in the bowels, which made him writhe about in bed. He vomited, and at the same time his bowels were again moved, the second motion consisting only of mucus tinged with blood. Abdominal pains came on in paroxysms about every ten minutes, causing him to cry out, and each time accompanied by the passage of mucus and blood.

10.30 a.m.—I saw him. He was very pale, with a pinched appearance. Pulse rapid and weak. Between the intervals of pain he lay exhausted. As soon as a pain came on he cried out and rolled about the bed. Each paroxysm of pain was followed by an evacuation of mucus and a little blood. On examining the abdomen it was quite flaccid. There was no distension. Palpation of the whole abdomen was allowed without any complaints until the hand came to the right iliac fossa, where a small elongated mass, apparently about three inches in length, could be felt. This was very tender to the touch.

Patient was immediately put under chloroform, and

the mass previously discovered could be still more distinctly palpated. Per rectum nothing could be felt.

Insufflation and massage were first tried, but without effect. Large enemata of hot water were next administered, but the tumour remained unaltered. The following operation was then performed:-

An incision three inches long was made over the seat of the swelling, and as soon as the abdomen was opened the cæcum was drawn out, and an intussusception discovered of the ileo-cælic variety. Dr. McGregor, who assisted me, held the small intestine close to the intussusception to steady it, and grasping the colon beyond the intussuscepted portion, I was able, by manipulation, with comparative ease to release about one foot of gut. To prevent recurrence, the mesentery of the intussusception was shortened by inserting a few fine silk sutures parallel with the gut, as advised by Senn. The abdominal incision was closed with three layers of silk sutures, and the patient put back to bed in twenty-five minutes, apparently little the worse for the operation.

After-progress and Treatment.—Patient was kept for the first twenty-four hours on raw beef juice and white wine whey. Small doses (III iij) of liq. morph. mur. were given every four hours. There was no sickness or diarrhoa after the operation. The bowels

acted naturally twice on the fourth day, and morphia was given to check a tendency to diarrhea.

The subsequent history was uneventful. The highest temperature was 99 6 degs on the evening of the operation. The dressings were first removed and the wound found healed on the tenth day.

REMARKS.

The four cases recorded illustrate four possible

terminations of intussusception.

Case I. is an example of recovery without operation, a result which statistics say occurs in 3 per cent. of cases, and one consequently as rare as it is for-

Case II. may be regarded as a typical example of the disease allowed to run its natural course, with the usual result—an agonising death. The pathological interest of the case lies in a point which, perhaps, does not appear sufficiently clear in the record. An invagination of the ileum into the excum at the ileo-cæcal valve had been the primary leison. Then the intussusception and the ascending colon were invaginated into the transverse and descending colon. sigmoid flexure, and rectum, so that a section through the mass at the rectum would have shown: First, the wall of the rectum; second, a layer of ascending colon; third, another layer of ascending colon near the cæcum; and fourth, the ileum. In other words, it was an intussusception of an intussusception.

Cases III. and IV. both illustrate the failure of injections. Case III. the disadvantages of postponed, and Case IV. the advantages of early, operation.

So far as I have had opportunities of judging of such cases, they should be regarded as more related to strangulated hernia than to intestinal obstruction. In both, intestinal obstruction, due to a mechanical cause, exists; in either, delay in the removal of the cause is equally serious. Both can only be treated properly by mechanical measures, and in both an accurate and early diagnosis is possible. The surgical rule for the treatment of irreducible and strangulated hernia is to give the patient chloroform at the earliest possible moment, to try gentle taxis, and, if this fails, to operate at once—without allowing the patient to recover from the anæsthetic This rule, it cannot be doubted, has been the means of saving many lives. A similar rule should have as beneficial results when applied to the treatment of intussuscep-

In Case IV. chloroform was administered with the understanding that injections were first to be tried, and, these failing, operation was to be at once proceeded with.

I believe that the mortality of cases operated upon for intussusception has been greater than that of cases operated upon for strangulated hernia, only because in the former, operation has been delayed, in the latter has been promptly performed. Why should the operation for intussusception be delayed? I can find no reason. When the symptoms are such as have been described—vomiting, paroxysmal pain, passage of blood-stained mucus, and tenesmus—careful examination of the abdomen and rectum are likely to lead to a correct diagnosis, and this should evolve definite action. Probably the bad reputation acquired by ordinary operations for intestinal obstruction, and the uncertainty of prognosis without operation in such cases, has had some influence in delaying the acceptance of prompt operative treatment for intussusception; but in an ordinary intestinal obstruction case the diagnosis of intestinal obstruction may not be arrived at for some days; the prognosis may remain uncertain; and then comes the difficulty of ascertaining and locating its cause; in the majority of cases operated upon a large opening has to be made in the middle line of the abdomen; a considerab amount of troublesome and dangerous work has to be done to find the cause, and, if that is found, there is frequently no possibility of dealing with it.

In intussusception, as in hernia, a tumour is felt. A small incision can be made over it, the lesion can be discovered without difficulty and reduced-in the early stages readily—without serious disturbance to

the patient's condition.

Without drawing further conclusions in parallel lines, as could easily be done, I would again emphasise the comparison between strangulated hernia and intussusception, to express my belief that, as in the treatment of hernia, taxis is gradually losing ground; so in intussusception, injections and such-like measures will in the future be less employed, for early operation in both I believe to be the safest and most satisfactory treatment.

NOTES ON THE PLAGUE. (a) COLLATED

By SIR CHARLES A. GORDON, K.C.B., M.D., Surgeon-General (retired), Hon. Physician to Her Majesty the Queen.

(Continued from page 399).

11. OTHER METHODS.

Mr. J. V. Ramasamy Naidu, of Madras, treated plague on the old successful plan by neem and olive oils. The "Baroda plague pills," largely believed in by the natives, consist of quinine 2 grs., camphor gr. 4, ipecacuanha gr. 4, carbolic acid minim 4. They were used by thousands as a preventive; from the date of their being so the disease began to decline and speedily disappeared Captain Wilkinson believed that patients treated did better than those untreated. Dr. Seymour used the following prescription which had effected 75 per cent. of recoveries against 21 where the patients were not so treated :-Acid carbolic liquid, 3 minims; quin. sulph, 5 grains; acid sulph dil., 10 minims; glycerine (?) minims; aqua to one ounce every four hours. Colonel Maconachie said that no treatment stopped the course of the disease. As already observed, inoculation was in certain instances supplemented by the administration of stimulants.

12. SEGREGATION.

Dr. Hossack stated that segregation was abandoned. The forcible removal of patients to hospital had practically ceased. He had not found cases recurring in one room, and thought that the abandonment of segregation had not produced bad results. Banerje said that the natives were opposed to isolation and segregation. Women would object to leave their homes for the short time necessary for disinfection, but they would prefer that to segregation. Mr. Winter that in the segregation camp for the Hurdwar Union very few cases of plague occurred, and the disease soon ceased. Colonel Crofts stated that measares of segregation and evacuation in the village of Khandraoni were successful. Mr. Giles: that during the epidemic at Kurrachee evacuation was the most effective measure; universal segregation was dangerous and unnecessary. At Bombay Major Roughton recommended the adoption of the system employed in London during the plague of 1665 as related by Defoe, of locking up the houses and confining the inhabitants inside unless the natives underwent segregation.

13. DISINFECTANTS.

The rules at inspection camps were elastic, and disinfection of goods was evaded. At Calcutta it was said that plague cultures had been found in the clothes supposed to have been rendered sterile by

⁽a) From reports principally in the Times and other papers.

disinfection. The natives were educated up to disinfection, and carried it out themselves. The disinfection measures of the authorities were insufficient in face of the opposition of the people. Dr. Banerjee said that disinfection was impossible owing to the nature of the dwellings. The inhabitants mixed indiscriminately. Only the highest classes disinfected their dwellings; the poorer were not used to taking proper steps for disinfection. A bustee could be disinfected as a whole, but not partially. The people objected to disinfection because they thought their goods would be destroyed.

Surgeon-General Harvey said that wholesale dis-infection was not thorough because of the lack of European supervision; the natives shirked it. Captain Clark advocated the use of disinfectants, and suggested that steam disinfectors should be provided. Captain Jenny, at Kurrachee said that disinfection of ships' cargoes had proved unsuccessful.

At Baroda, nitric peroxide was deemed the best disinfectant, as it destroyed both the smell and the infusoria of sewage. At Satana evidence went to show that chemical disinfectants had not proved successful.

14. SANITARY MEASURES.

At Calcutta Dr. Justice believed that plague did not spread because the native huts were better ventilated and lighted than those of Bombay. Dr. Bose considered that persons cooped up in ill-ventilated houses were generally infected; those living in the open air escaped. Dr. Hossack disagreed with Dr. Justice as the cause of plague not spreading being the better description of native huts. They were being gradually removed. Surgeon-General Harvey considered that evacuation was theoretically excellent, but in large towns impossible. Colonel Fullerton said that passengers and crews were subjected to observation before landing on the Baluchistan coast. Passengers by railway underwent medical inspection only at first. When plague spread to other localities besides Kurrachee a segregation camp was established at Sibi, and passengers were detained ten days. Captain Bingley said that municipal camps had been tried at Bombay but were not successful. A camp in his own district at Calcutta was very successful.

Colonel Thomson said that medical inspection of

railway passengers, segregation and disinfection gave to Agra a remarkable immunity from epidemic diseases generally. At Hurdwar evacuation was the chief measure adopted. Mr. Winter, that the measures taken were evacuation of infected blocks, segregation, burning of houses, disinfection of houses and property. These measures were completely successful. Colonel Adams, that cordons were placed in the infected area in Sirohi, the result astisfactory. Captain Grant said that in the Agra district the infected were sent into camps, and the epidemic Infected huts were burned; houses unroofed, floors burnt, walls limewashed. Captain James, of Lahore, had known a case where the people had returned to a house after the lapse of thirty-four days, before the house was disinfected, and a number of the family were attacked. The most satisfactory measure was evacuation.

Captain Wilkinson said that in the Punjaub the measures adopted were segregation of patients and their friends, evacuation, disinfection of boles and roofs, and whitewashing: removal of floors, of huts, and burning them. Mr. Giles, that during the first epidemic at Kurrachee only the ordinary measures were taken. It ceased in July, 1897. During the second epidemic the measures adopted were segregation, hospital treatment, and voluntary camps. Colonel McCloghry said that at Kurrachee the whole town proper was evacuated, and the result was successful. Mr. Kaka, that after voluntary camps were formed the plague declined. Mr. Giles believed the continuance of cases among people who fled to the date plantations to be due to the insanitary nature of the ground. In January, 1897, the inhabitants of Kurrachee were encouraged to leave. Seventy-five thousand went from the city then badly infected, but the people in the afflicted area were restricted from leaving.

In the Cutch district evacuation, disinfection of clothes with carbolic acid, of houses with quicklime were the measures employed. At Nasik and Melegaon evacuation took place, and the epidemic stopped. Partial evacuation was inefficient when the plague was indigenous, but successful when the disease was imported. At Ahmedabad the houses were fumigated with sulphur; the walls washed with lime. In Baroda registration of deaths, removal of sick to hospitals, isolation of contacts, disinfection, proper disposal of dead bodies, voluntary inoculation, and evacuation. Nasik town was successfully evacuated. At Daman the salt frontier force was successfully used as a cordon, and kept infection from British territory. The epidemic was of short duration, owing to evacuation measures. At Mazagon, after the population were removed into camp, few cases of plague occurred. In Kolalba district European supervision overcame the disease, i.e., its second epidemic. At Poonah and Kirkee, the measures adopted were the removal of the sick, the segregation of contacts, evacuation, disinfection, the establishment of a sanitary cordon, and inoculation. Satara there was immunity among those living in the open air, and among Europeans. Fresh air prevented the disease. There also the unroofing of infected houses was found to be the best measure. Kiln burning was neither theoretically nor practically sound. After evacuation no houses were re-occupied in less than four months. At Ashmednuggur, plague and cholera ceased after disinfection of the city.

To be concluded in our next.

Clinical Records.

ROYAL HOSPITAL, BELFAST.

Ulcer of the Esophagus. (a)

By Dr. J. A. LINDSAY, of Belfast.

I wish to bring before you a case of ulcer of the esophagus, resulting in abscess of the posterior mediastinum, rupture into the lung, emphysema of the face and neck, and death. The patient, a male, et. 59, was admitted to the Royal Hospital, Belfast, suffering from abdominal pain, distension, and collapse. A few hours before admission, as the result of drinking a bottle of stout, he had been seized with severe pain in the epigastrium, and had vomited. There was a history that the patient had suffered for some weeks from pains in the abdomen, to which he had not paid much attention. On admission to hospital he complained of pain in the epi-gastrium, and weakness. The abdomen was moderately distended, and tender on palpation in the epigastric and in both lumbar regions. There were signs of a large effusion into the right pleura. The temperature was 100 degs., the respirations hurried, and the urine contained much sugar and a little albumen. Towards midnight of the day of admission the patient's state began to change for the worse. For the first time a puffiness of the left eyelid was observed, which rapidly extended over the left side of the face and neck, and the upper portion of the left chest. This was found to be superficial emphysema. The pulse was now 120, weak and irregular, the respirations 56, and the patient much collapsed. The diagnosis presented great difficulties. The possibility of a gastric ulcer which had ruptured through the dia-

(a) Read before the Royal Academy of Medicine in Ireland March 10, 1839.

phragm into the lung was considered, but the history was, on the whole, against gastric ulcer. The abdominal pains had been vague, shifting in position and not severe, and there had been neither hæmatemesis nor melæna. The indications were held to be too obscure to justify operative interference. The patient gradually sank on the following day and died at 11 o'clock p.m., stant of the following tay and thet at 11 o check p.m., thirty - seven hours after drinking the bottle of stout, and twenty-three hours after the first appearance of emphysema of the face and neck. An autopsy was made twenty-two hours after death. Emphysema was found to be well marked in both media-stina, especially the left. The right pleural cavity contained 50 ozs. of serum, rather flocculent in character. There were also a few ounces in the left pleural cavity. Signs of acute pleurisy were well marked on both sides. Two inches above the cardiac orifice of the stomach there was an elongated ulcer, 1½ inches long, in the esophageal wall. In the lower part of its extent it in-volved only the mucous membrane. The edges of the ulcer were thickened but not indurated. There was no evidence of any malignant deposit around the ulcer or elsewhere in the esophagus, and no secondary deposits in any of the viscera. A sinus connected the ulcer with an abscess in the posterior mediastinum between the cesophagus and the aorta. This abscess had ruptured into the lung at its root, and air had extravasated along the deep fascia, and also along the superficial fascia of There was no communication between the abscess and the pleural cavity. The aorta was atheromatous, as were the arteries of the base of the brain. There was chronic thickening of the pia and arachnoid. general congestion of the meninges, and edema of the brain substance. The puncta cruenta were well marked. The kidneys were much congested and the liver fatty. The pancreas was normal. The view taken was that the ulcer in the esophagus was probably of syphilitic origin. The patient had suffered some years before from what he called "blood poisoning"—which may have been syphilis. No definitely syphilitic lesions were found at the autopsy, but the state of the brain lent some support to the theory of syphilis.

BRITISH GYNÆCOLOGICAL SOCIETY.
MEETING HELD THURSDAY, APRIL 13TH, 1899.

H. MACNAUGHTON-JONES, M.D., President, in the Chair.

ABDOMINAL CAUSES OF DEATH AFTER CŒLIOTOMY.

Dr. W. J. Smyly read a paper, which will be found in another column, introducing a discussion on this sub-

The President observed that the paper was one of great practical importance and interest. It touched on all those vital points in the post-operative period which made even the most experienced operator anxious, and the interest in them was universal, because no surgeon knew beforehand whether he might not have to face one or other of the complications mentioned. There were other accidents, to which Dr. Smyly had not referred, but which would, no doubt, be mentioned in the course of the discussion.

Professor JAPP SINCLAIR (Manchester) said that he had not heard a paper dealing better or more concisely with its subject than that of Dr. Smyly; and on all essential points he found himself in entire accord with the author. With regard to shock he had nothing to say to its nervous origin, as to which he did not feel very convinced; he took the view that hæmorrhage played a predominant part in its causation. All the cases of shock which he had seen had been due to hæmorrhage, the result in some cases of accident, in others of blundering. He therefore looked on shock and hæmorrhage as equivalent, with a very few exceptions such as cases of heart disease. One cause of death was a want of tone in 'the bowel, which in some cases was chronic, the result of chronic constipation; and he

always operated on such cases with great anxiety. These army's operation of such cases with great antiety. These patients might go on all right for a few days, then symptoms of intestinal paresis came on and the patient succumbed. Examination after death showed nothing to indicate ileus, pressure on the bowel, or any other form of intestinal obstruction; and before death there was no indication for re-opening. In one case he was told by the nurse that almost the whole of the contents of the bowel came away half-an-hour after death. Another cause of bowel trouble was pressure, such as that of a hæmatoma in the broad ligament. He had a case of this kind, and it was only by the exercise of great force, such as only extreme necessity would justify, that he was able to get a rectal tube past the swelling and the symptoms then subsided, and the patient got quite well. He agreed with Dr. Smyly's remarks about ileus, but would add that as regards prophylaxis, he thought they were often too late in giving aperients. When there was any doubt, peristaltic action could almost always be set up by calomel, which he gave on the day after opera-tion, in hourly grain doses. In cases where raw surfaces had to be left, through the separation of adhesions or removal of portions of peritoneum, he always liked to leave some saline solution in the peritoneal cavity; this allowed the bowel to float and diminished the risk of bowel adhesions. Of course, in this case they must not drain. With regard to peritoritis, he believed that there was a non-septic form, and in these cases purgation was successful; but he did not believe that purgation succeeded when the peritonitis was septic; on the contrary, it might make matters worse. As far as he knew, no micro-organism except the streptococcus led necessarily to a fatal result. His experience of anti-streptococcic serum coincided with that of Dr. Smyly; the serum might reduce temperature, but he had not seen a case where it had saved the patient's life. He thought that Dr. Smyly gave undue credit to Tait and Bantock in the advocacy of cleanliness; he remembered being very shocked at a description of the way in which Tait flushed out the peritoneum, teaching that it would do no harm to flush out with Birmingham tap-water. Judging from the agitation to secure purer water in that city, he thought the tap-water there was not above suspicion. Such teaching was not one of cleanliness, and was likely to encourage carelessness among young operators. He had just received a pamphlet advocating the flushing of the peritoneum with saline solution, as if it were a new thing; his impression was

that he had recommended this some twenty years ago.
Dr. WILLIAM WALTER (Manchester) thought Dr. Smyly was right in drawing attention to shock as in itself a cause of death. When he was a student, a sur-geon never did an ovariotomy without first asking a physician to test the condition of heart and kidneys; he thought this precaution was neglected now-a-days. Too often a patient came in one day and was operated upon on the next. Delay was especially necessary when a patient had been badly fed and came from unhealthy surroundings. He must confess to making a mistake sometimes in this matter, owing to the exigencies of hospital practice. The best way to prepare against the tendency to shock was to fortify the heart's action with strychnine, and to operate in a warm room, guarding against cooling of the intestines with warm compresses, &c. Perhaps the best thing of all was the Trendelenburg position; since this had been introduced patients seemed to bear difficult operations much better. It was often difficult to diagnose shock from internal hæmorrhage. In guarding against the latter, he thought they were sometimes not quite careful enough. For instance, if the pedicle had been cut too near the ligature, the surgeon was apt to think it might do, even if he did not feel quite satisfied about it; whereas he ought not to be above tying it again. He would remark in this connection that the Staffordshire knot tended, in his connection that the Stanfordshire knot tended, in his opinion, to cause hemorrhage, for it often cut through the tissues almost like a knife. Proper attention to the pedicle was one of the most important safeguards against hemorrhage. Another mistake was in having a transfixion needle with too large a point. This might lead to tearing of a vein and fatal hemorrhage. He had lost one patient in this way. He believed that

Digitized by Google

death might be due to violent emotion. Thus he had a case in which the patient had recovered so far as to be sitting up. She was told some bad news, and hæmorrhage coming on suddenly led to a fatal result. Hæmorrhage from adhesion sites was always difficult to deal with, especially as at the time of operation there might be no sign of it, and on the return of consciousness it might come on. When secondary hæmorrhage occurred he thought that, unless one were actually on the spot, it was almost impossible to save the patient. If it were necessary to reopen for hæmorrhage, he advocated the plan of opening the vagina instead of the abdomen, washing out with very hot water and packing with gauze. This procedure saved time, and was attended with less shock. In any case, the less one could do the better. By trying too much they might lose the patient. For septic peritonitis, reopening the abdomen did not answer, for the patient was seldom able to stand a second operation. He did not believe in opium and morphis in the treatment of peritonitis, for they only tended to increase the intestinal paralysis. He preferred calomel and salines given early. Dr. George Elder (Nottingham) observed that any

one experienced in abdominal work must always approach a case with some anxiety. He agreed with Dr. Walter that in some cases bad results might have been due to too great hurry in operating before the patient was fit to stand it. It was well to wait three or four days, and to employ the time in learning the patient's habits, in getting her accustomed to her surroundings, and in seeing to the condition of bowels and kidneys; he regarded the latter as most important. To illustrate the value of the patient's history, he might mention a case he saw 15 or 20 years ago. He performed ovariotomy, and after or 20 years ago. He performed ovariotomy, and after doing well for a few days the patient collapsed. The matron, a most competent woman, discovered that the patient had been in the habit of taking large doses of laudanum; whereupon the gave her a drachm at once, and the patient rallied and eventually got well, the laudanum being continued for several days. Shock was not so often seen at the present time because operations were done more quickly and under better conditions. He did not like to operate on any woman who had made up her mind that she was going to die. No doubt many deaths formerly put down to shock were really due to hæmorrhage. There was one symptom which he had not seen described, but which he believed to be pathognomonic of hæmorrhage — viz., intense pain, of a shooting character, uncontrolled by morphia. Dr. Walter had said that his experience of reopening the abdomen had been unfavourable, and he had compared the results with those of reopening for peritonitis. But he did not think that the cases were comparable; he had rarely seen a case in which the abdomen had been reopened for hæmorrhage, where the patient did not recover. As regards peritonitis, he believed that fatal cases were due to sepsis. He was surprised to hear Dr. Smyly give the credit of aseptic surgery to Bantock and Tait. He was himself an old pupil of Lister, and he felt sure that what they knew of asepsis was due entirely to the untiring efforts of Lister during the last twenty-five years. There was one kind of sepsis which no antiseptic precautions could get rid of, and which only time could render harmless, and that was the sepsis arising from operations for puerperal peritonitis or for the clearing out of a putrid placenta. He had lost two patients through operating too soon after such cases: one was an ovariotomy which he did four days after an operation for puerperal fever.

Mr. J. W. Taylor (Birmingham) said that they might gather from Dr. Smyly's paper that the cause of death after cœliotomy was in many cases shock; but he did not think that he had ever seen a death due directly to shock, though he had seen cases where death was due to sepsis, predisposed to by hæmorrhage and shock. As regards ileus, he thought the use of dry sponges might lead to it; for he had had more difficulty in getting the bowels open after the use of dry than after moist asepsis. The discussion seemed to have centred round the question of asepsis; he believed that the three chief factors in the production of sepsis were sponges, hands, and the breath of the operator. He

had had the opportunity of seeing work in Birmingham under conditions that could not be considered aseptic; and this experience had helped him to see which details were of more and which were of less value. He had not seen a death due to the use of tap-water; nor had he seen one attributable to clean instruments, even when these had not been boiled; but in the three factors he had mentioned he believed the chief danger lay. With regard to treatment, he agreed with what had been said as to the value of calomel; he always tried to get the bowels open by six o'clock on the morning following the day of operation; if they were not open them, he gave small doses of calomel. There was another way to combat sepsis in cases where the kidneys were acting badly, and that was by means of the hot air-bath; he believed he had seen this treatment save several cases. In watching two or three outbreaks of peritonitis, he had seen that the characters of the outbreaks varied; probably there were several kinds of peritonitis due to different kinds of micro-organisms; and they might hope for further light on the subject when they were able to distinguish not only between the clinical types, but also between the micro-organisms concerned. In conclusion, he expressed his thanks to Dr. Smyly for his valuable and interesting paper.

Dr. Heywood Smith said that a point which Dr. Smyly had omitted was the question of the idiosyncracy of the patient. There were some patients who were described as slow healers, and who tended to go to the bad; and it was well to keep such cases some days in hospital before operation. With regard to sepsis, he would observe that there were many different practices with regard to ligature material; he was sure catgut had caused inflammation in some cases. He agreed with Dr. Doyen's dictum, operer vite et bien, and as every time-saving detail was of importance, he thought that Greig Smith's forceps-needle was a useful thing; it was a fine forceps, passed through the tissues as a pedicleneedle; it was then opened, and the ligature could be

rapidly seized and drawn through.

Dr. Dudley Buxton said that there was one aspect of anæsthetics which bore upon the discussion, viz., the relation of chloroform to shock. The shock of operation was, to a great extent, caused or enhanced by the physical effect of chloroform, which was most marked in anemic persons, and in those who had lost much blood during operation; and the explanation of the action of chloroform under these conditions was to be found in the alteration of pressure of the abdominal contents after the abdomen had been opened. For the maintenance of intra-abdominal pressure the action of the recti and of the diaphragm was needed; and during collotomy this action could not be exerted. When, in addition, the action of the nerve centres was weakened by anæmia the effect of chloroform in lowering blood pressure through the filling of the "abdominal pool" was greatly enhanced. Consequently, the mere opening of the abdomen made the patient more liable to shock from chloroform than was the case in any other kind of operation. The Trendelenburg position minimised shock by assisting gravity in the prevention of cerebral anemia.

Another important point about chloroform was its iability to cause post-operative hemorrhage. Some operators preferred chloroform because they got less bleeding during the operation, but the lesser hemorrhage was due simply to the depressed state of the circulation, and as soon as the anæsthetic was eliminated from the system hæmorrhage was liable to come on. These two points came fitly within the scope of the discussion, but the general question of the choice of an anesthetic was too large to enter into then.

Dr. T. EASTES (Folkestone) mentioned two cases of pseudo-ileus. The first was a patient suffering from myoma and ovarian cyst. The latter was removed by ovariotomy, the myoma being left. After a few days symptoms of ileus came on. He opened the abdomen and put a tube into the colon, but she died, and he thought the death was due to the myoma acting as a ball-valve, and keeping up the obstruction. In the other case the obstructive symptoms were due to hæmatocele, and he carried out a much more active treat-

ment; thus, he stopped all feeding by the mouth, gave nutrient and aperient enemata, and small doses of calomel. The result was satisfactory, and he believed

that in such cases a similar plan should be adopted.

Dr. R. T. Smith believed that patients might die of simple shock. Thus he had a case of double ovariotomy; the operation presented no difficulty, but an hour after the patient's pulse was 160, and she died in two days. The autopsy showed no hæmorrhage nor other cause of death, and he believed that it was due to vasomotor paralysis. But she had also had a good deal of nervous disturbance. For the prevention of ileus calomel was good, begun early, but he thought it was even better to

give it three or four days before operation.

Mr. Charles Ryall said that there were cases where the shock was quite out of proportion to the time taken by the operation, especially operations involving the mesentery, and hysterectomy. There was always shock at the moment when the uterus was being severed. In the preventive treatment of shock, flushing the abdominal cavity was a good thing. For acute obstruction he held that the proper treatment was to open the bowel and relieve it of its contents, in just the same way as tracheotomy was done for respiratory obstruction. was in the habit of giving calomel in the evening of the day of operation and an enema next morning. If septic peritonitis came on, the treatment was that of an abscess: drugs were useless.

Dr. Smyly observed that he had no idea of detracting from Lord Lister's fame: antisepsis came first, asepsis later, and in consequence of antisepsis. But Mr. Tait first showed that antiseptics were not only useless, but injurious to fresh wounds; he also emphasised the importance of avoiding contamination of the operator's hands, and this teaching had led to the modern aseptic

methods.

The President said that he did not know when Mr. Tait first laid stress on the importance of clean hands, or showed that antiseptics might be toxic; but he was sure that when Lister first introduced the antiseptic treat-ment, 25 years ago, cleanliness was laid down as one of the most important points. Moreover, every modern aseptic operation included antisepsis at some time before or during the operation. He believed that death from shock was almost always due either to hæmorrhage or to operation on a patient whose condition was not good enough for operation. One of the most important points in an operation was the arrangement of the peritoneum and omentum. He had recently had a case of death after hysterectomy from peritonitis arising in the track of the wound, although every possible care was exercised: and so it was important that the possibility of this should be borne in mind. The possibility of auto-infection also should be remembered. Dr. Sinclair's remark that the streptococcus was the only harmful micro-organism was not in harmony with the views of bacteriologists, and he thought Mr. Taylor was right in saying that there were several kinds of pyogenic organisms. The question of the operator's breath was an important one; in Vienna, Chrobak and his assistants operated with a kind of facial maskon. The kind of case that he most dreaded operating on was not the patient who thought she was going to die. but rather the nervous woman who threw herself about after operation; to tie her down and to give her freedom both had drawbacks; in the former case the patient got worse, in the latter she might break open the wound. Kelly thought that the lesser evil was to give her freedom. In conclusion, he thanked Dr. Smyly for his valuable paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING RELD FRIDAY, MARCH 10TH, 1899.

The President, Dr. J. W. MOORE, in the Chair.

ULCER OF THE (ESOPHAGUS.

DR J. A. LINDSAY, of Belfast, read notes of a case of ulcer of the œsophagus, which will be found under "Clinical Records."

Dr. FINNY said he could not understand how mediastinal emphysema could reach the eyelids, though, of course, there were records of emphysema of the eyelids from rupture of the air passages.

Dr. HAYES related the case of a young man dying of

rapid general tuberculosis, who two days before death complained, after drinking some milk, of intense pains over the sternum. An autopsy showed the extravasation of milk surrounding the esophagus, which had two

ruptures about half-way down.

Dr. Coleman referred to the case of a boy who, after swallowing a large fish bone, developed not only pus, but also air in pericardium, due, no doubt, to the fish bone, ulcerating through the esophagus. He believed that the gas in the pericardium was due to decomposition, and this was also a possible explanation of the emphysema which was present in Dr. Lindsay's case.

The President suggested that the lesion was

syphilitic.
Dr. Lindsay, in reply, said that it was the condition of the vessels of the brain that had suggested to him its possibly syphilitic origin

TUBERCULOUS MENINGITIS (?)

Dr. LINDSAY also read notes of a case of probable tuberculous meningitis which terminated in recovery. The patient was a young lady, at. 19, seen in consultation with Dr. King Kerr, of Knock, Belfast. There was tubercle on both sides of the house, and patient's mother and younger sister are sufferers from phthisis at the present time. The patient had had tuberculous glands excised from the neck a few years ago. She had suffered from periodic headaches, but had been otherwise healthy. In November, 1898, she took an attack of ill-defined pleurisy, with some effusion in the right side. This pursued a slow course until December 3rd, when she first complained of headache. Next day the headache was more severe and vomiting set in. On December 5th the headache was severe and continuous. vomiting frequent, tongue thickly coated, temperature 101.5 degs., pulse 96, weak and regular, pupils sluggish, patient very restless, signs of fluid in the right pleural cavity. Next day the patient was delirious, tempera-101 degs. in the morning, and 102 degs. at night, tache cérébrale well-marked, pupils dilated and almost immo-bile, continuous vomiting, double optic neuritis. Late at night the patient became comatose and began to pass all evacuations involuntarily. The pulse remained frequent, weak and regular. The patient could swallow her milk, and sometimes showed signs of slight consciousness on being spoken to in a loud voice. This condition lasted from Tuesday, December 6th, to Friday, December 9th, when the coma began to abate. By Sunday, December 11th, the patient was much better, and thenceforward made an uninterrupted recovery. The treatment consisted in the continuous application of cold to the head by means of Leiter's tubes, and the administration of bromide and iodide of potash, with an occasional mercurial purge. The grounds for suggesting the possibility of the meningitis being tuberculous were— (1) the fact that mother and sister were sufferers from phthisis; (2) the presence at an earlier stage of tuberculous glands in the neck; (3) the existence of an ill-defined pleurisy, which may have been tuberculous.

Dr. Drury questioned the diagnosis of tuberculous

meningitis, and gave his reasons. He suggested that it was a case of rheumatic pleurisy with some rheumatic meningitis.

Dr. Finny also dissented from the diagnosis of tuberculous meningitis.

Dr. R. TRAVERS SMITH asked whether the choroid coat of the eye had been examined for the presence of tubercle.

The President thought as cases of tuberculous peritonitis could recover without operation so might tuberculous meningitis. He suggested that they should try the tuberculin test in these cases, and believed that both pleural effusion and the head symptoms were possibly due to the micro-organisms of pneumonia, which sometimes produced a very dangerous form of menin-

Pr. Lindsay, in reply, said that the President's suggestion of pneumonia had also occurred to him.

Tubercles were not found in the choroid, but the patient | was restless so that the examination of the eye was accomplished with difficulty.

NON-FEBRILE PNEUMONIA.

Dr. LINDSAY also read notes of a case of non-febrile pneumonia. The patient, a gentleman, et. 33, was seen in consultation with Dr. M'Kisack, of Belfast. There was a history of alcoholism. The patient first sought advice upon October 13th, 1828, for headache, sickness, abdominal pain, and malaise. The temperature was 98 8° pulse 80, respirations 20; no abnormal signs in the chest, tongue very foul. Next morning the patient felt better; the chest was examined with negative results; in the afternoon the patient sat for some time in the diningroom and talked with friends. About 9 o'clock p.m. it was noticed that his breathing was becoming hurried. He passed a restless night Next morning he was much worse, respirations 36, temperature in the mouth and in the groin 96.5°, well marked signs of consolidation of the right lower lobe-viz., dulness, bronchial breathing, and increased vocal fremitus; at 4 o'clock p.m. the temperature was 98° in the groin and 99° in the rectum, respirations 36, pulse 106 and very weak, patient much collapsed, but quite conscious. Crepitus was now audible over a considerable portion of the right lower lobe. The sputum was rusty. Towards evening the temperature for the first time began to rise, and at 8 o'clock p.m., it was 101°. Death took place at 9.30 o'clock, within twenty-four hours of the first advent of definite pulmonary symptoms. Alcohol, strychnine, carbonate of ammonia, digitalis and oxygen were administered, but without effect.

The President observed that there was nothing new He considered that the hypodermic in the apyrexia. administration of strychnine was one of the best remedies

in all the collapsed fevers.

Dr. Cosgrave mentioned a case of pneumonia in which the temperature remained subnormal throughout. He had tried hypodermics of strychnine, but they had had

Dr. LINDSAY, in reply, said he always gave strychnine in these cases.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD THURSDAY, MARCH 30TH, 1899.

DR. HUNT, Vice-President, in the Chair.

DR. ARTHUR HALL showed a case of linear ichthyosis

Dr. Sorley, a case of muscular atrophy from polyneuritis, following influenza.

Mr. ARCHIBALD CUFF exhibited and made remarks upon:—1. A case of hemi-hypertrophy. 2. A tumour

of the cerebellum.
Dr. Hunt, Dr. Arthur Hall, Dr. Hargreaves, Dr. Gwynne, Dr. Burgess, Dr. Keeling, Mr. Snell, Mr. Richard Favell, Dr. Martin, Mr. Sidney Barber, and Dr. Sinclair

White made remarks.

Mr. Simeon Snell introduced two patients. 1. Recurrent third nerve palsy, associated with migraine.

The patient was shown first before the Society in 1884, and the case is reported in the Transactions of the Ophthal. Society, 1885. The patient, a woman, is set. 23. The attacks of severe pain and sickness have recurred every three or four months, but recovery from the associated third nerve palsy has become increasingly imperfect. 2. Embolism of central artery of retina in a young woman, æt. 23.

Dr. MARTIN gave the notes of a

CASE OF CÆSARIAN SECTION.

The patient was a primipara, at. 23, a dwarf, and deformed. Her heighth was 3 feet 10 inches. She had a large square head, short arms, and thickening of the cartilages, and the ends of the long bones, especially at the wrists; the tibiæ were bowed. From measurements carefully taken before the patient left the hospital it was found that the distances were: between the crests of the ilium, 101 inches; between anterior superior spines, 10 inches; ant. post. diameter, 6 inches; inf. conjugate (with callipers), 1 inch; thickness of sacrum

(with callipers), 3f inches. She was admitted into the Jessop Hospital for Women at 2.30 a.m., April 13th, 1898, and was in labour at the time, The deformed condition of the pelvis was at once noted by the house surgeon, Mr. S. Barber, and the necessity for operation recognised. After consultation with the other members of the staff, Dr. Martin did a Cæsarian section successfully, the life of both mother and child being saved, the operation lasting thirty-five minutes. There was a smart dash of hemorrhage after the patient was put to bed; this seemed to be controlled by the subcutaneous injection of the 1-150th of a grain of citrate of ergotine. There was some bronchial trouble, and rise of temperature for four days after the operation, but both speedily subsided, and the patient made an excellent recovery, being discharged May 7th, 1898.

THE MEDICAL PRESS.

France.

FROM OUR OWN CORRESPONDENT.

Paris, April 21st, 1899.

DIFFUSE HYPERTROPHY OF THE BONES OF THE FACE. Ar the Académie de Médecine, M. C. Dentu read a paper on diffuse hypertrophy of the face and of the cranium, which he said was generally bilateral, but could be also limited to one group of bones. To well understand the nature of the affection it should be remarked that its evolution was marked by subscute or acute phases, which had, for consequence, the exaggerated development of certain portions of bone already abnormally developed generally. His personal observations lead him to formulate the following propositions:-The lesions are not always symmetrical; generally the superior maxillary was the centre of unilateral hypertrophy, but he had also seen the temporal bone attacked. On the other hand, the symmetry belonged sometimes to pediculation, having no relation with the diffused hypertrophy. Sometimes also the lesions commence within the cranium. Far from being constituted solely by osseous substance, the tissues could present to histological examination, fibrous and embryo plastic elements. The malady lasts generally several The prognosis is usually benign, but vears. the affection could abridge life by grave functional troubles of the mouth (difficulty in mastication of the nose (obstacle to respiration), the head (compression of the brain and irritation of the membranes). In his personal cases he observed pseudo-meningitis, convulsions, epileptiform seizures, delirium, and dementia.

Partial extirpation of the osseous masses gave good results in his hands. He considered, then, that in future diffused hypertrophy might be arrested by practising at the outset abrasion of the parts, combined with the application of the thermo-cautery.

TUBERCULOSIS OF THE TESTICLE.

M. Berger spoke on the treatment of tuberculosis of the testicle, and said that where the lesion was limited, castration should be performed, as frequently a definite cure was the result; where the tuberculosis was advanced, and the patient presented pulmonary lesions, an operation was useless.

PERUVIAN BALSAM AND SCABIES.

At the Société de Dermatologie, M. Hallopeau related two cases of death in children after the application of the treatment of scabies by balsam of Peru. He thought that these fatal results were due to impurities of the drug, but it was possible that the child presented as regards that agent a much greater susceptibility than an adult.

M Fournier said that he constantly employed pure balsam of Peru in the treatment of scabies in adults and children, and never met with an accident. Another speaker said that he had renounced the use of pure balsam on account of its too adhesive properties, in favour of a 30 per cent. mixture with vaseline.

TRYCOPHYTON TONSURANS.

Ringworm of the scalp is, as the majority of skin diseases, difficult to treat. All kinds of anti-parasitic remedies have been tried with variable success; iodine liniment, chrysophanic acid, acetic acid, sulphurous acid, corrosive sublimate, carbolic acid, &c. Recently M. Balzer, of the St. Louis Hospital, has employed strong solutions of lactic acid, and recommends it highly. After washing the parts with alcohol and ether, he applies a solution of lactic acid 3ss., and alcohol 3j., rubbing it in until redness is obtained. The pain resulting is not very sharp, and subsides in a quarter of an hour. The solution is applied twice a day. To complete the treatment, the patient is recommended to wash the parts with a sublimate solution (1-2,000). Out of nineteen cases thus treated fifteen were cured in less than three months, three others were improved, while one resisted the treatment.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 22nd, 1899.

At the Society for Innere Medizin Hr. Hirschlaff reported a

FATAL CASE OF LEUCEMIA.

A woman was admitted into hospital in September last. For some months past she had suffered from steadily increasing weakness. There was leucæmia, with enlarged deeply notched spleen. The patient had died the day previous to the meeting. Three weeks before, pleuritic exudation took place, after which her condition became very bad. On the day of her death she complained of difficulty of swallowing, from pain in her neck. Examination showed extreme swelling, of a snow white uvula, although no decoloration had been observed before. (The throat was examined daily in all cases of leucæmia.) The swelling increased rapidly, in an hour the left palatal arch was affected and then the tonsil. Two hours later extreme stridor came on and the patient died from suffocation. As regarded the blood the condition was one of myelogenous leucæmia. The proportion of white to red blood corpuseles was 1 to 6, there was great increase in the polynuclear cells and nucleated red blood corpuscles, the mononuclear cells were not very numerous, and there was neurophile cornification. The change in the medulla of the bones was considerable, it was a reddish grey, the spleen weighed 51 lbs., the liver was large, and all the lymphoid organs were much swollen. The microscopic preparation showed only medullary cells. The case appeared strongly to support Ehrlich's theory, according to which the spleen played only a secondary part in the elaboration of the blood, the first being played by the medulla of bones.

Hr. Litten would also draw attention to the latter point. The clinical features were rendered interesting

by the rapid tumour formation leading to suffocation, which was so rapid that there was not time for trachectomy. In an acute case he had seen an equally rapid formation on the hands, but in a chronic case like the one before them he had never observed such changes.

Hr. Benda did not agree with the previous speaker as to the nature of the swelling in the throat. It was cedema in a mucous surface changed by leucæmia. Such a rapid development of a tumour did not appear to him to be quite possible.

Hr. Litten agreed that there was cedem, but the principal change was thickening of the tissues.

Hr. Hirschlaff added an explanation of the condition of the blood that with the advance of the disease of the bone marrow, at last only the unripe cells, the mononuclear were carried into the blood current.

At the Surgical Congress Hr. Koing read a paper on the

HISTORY OF FREE BODIES IN JOINTS, in which he attributed them to a dissecting inflammation. He was not the first to account for their origin in this way, but lately he had been able to study them both clinically and ætiologically more sharply. During the last twenty years he had had seventy cases of free bodies in the joints, three in consequence of arthritis deformans, sixteen after injury; there were ten cases to exclude as the elbow or knee-joints were not the site of the bodies, there were then left thirty-six cases, to which the above ætiology did not apply. A number of the cases had had rheumatoid affections, that had also attacked other parts than those in which the free bodies were. Then there was pain and crackling in the joint, then certain movements could not be performed. He would not go further into the well-known symptoms peculiar to free bodies in the joints, but he would observe that their occurrence was generally preceded by injury. He then went on to describe the bodies themselves, and to mention various conditions that had led to their origination.

Hr. Kocher, Berne, read a paper on
THE CONDITIONS OF SUCCESSFUL OPERATION IN
EPILEPSY

He thought pessimism in regard to operation for epilepsy had been carried too far. From recent experience he had concluded that the method of operation practised had not been the right one. V. Bergmann had introduced an improvement by removing the cortical portion from which the epilepsy started. About 10 per cent. were cured in this way. Since the eighties the speaker had operated after a theory of his own, and had obtained six complete cures in traumatic epilepsy. He had collected 175 cases of operation, only calling those cures that remained well at the end of three years, although epilepsy sometimes returned even later than that. In this investigation he was able to determine that that treatment was successful that attacked the cause of the epilepsy direct. After extraction of foreign bodies from the skull, and especially from the brain, 88 per cent. of recoveries took place. In the latter cases, where the dura was incised, the results were the best. He assumed that an essential cause of the occurrence of attacks was tension, which was relieved by incision of the dura. Perhaps this reduction of tension was the factor in these cases that had been cured after incision of the cortical centre, and also in those cures in which the centre could not be determined by electricity.

In his successful cases the covering over the opening had remained soft, so that "giving" could take place on pressure, whilst in the unsuccessful ones, the covering had become bony or at least of tense connective tissue. If the principal factor of the attack was assumed to be a cicatrix or adhesions, operations should not be performed, as a cicatrix was always left by them. But these need not be feared. Aseptic soft cicatrices, even when they projected into the brain, almost never caused epilepsy. Guinea pigs could be made epileptic by a simple blow on the head, and in these cases the blood pressure was increased fourfold. If the animals were then operated on and a lateral ventricle opened, the epilepsy ceased. An ætiological connection between increased pressure and epilepsy had thus been experimentally proved. In this way cysts and collections of fluid of all kinds within the brain easily gave rise to epilepsy.

APRIL 26, 1899.

According to these views, we had first of all in our operation to remove all local irritation, such as foreign bodies, and then take measures for reducing local and general blood pressure within the calvarium. The dura when incised should not be sutured, but should rather be excised, and the defect should not be covered by bone. In penetrating wounds of the head, the damage was not caused by the opening, but by the firm closure of the skull.

Hr. V. Bergmann said it was yet to be determined what was the nature of epilepsy? and then there was the proposition that there was no epilepsy without spasmodic changes in the brain. This condition was congenital, and it would not be too much to say that in nine-tenths of the cases of epilepsy, whether traumatic or not, there was a hereditary tendency. If we took from the remaining tenth all the cases in which infective diseases were the cause, the remainder would be very small. Hereditary disposition could not be assumed when the attacks began after the 20th year. As to the cases operated on it was very difficult to determine whether they had a hereditary predisposition or not. There were two categories of causes of epilepsy-1st, the supposed epileptic change in the brain, which could be treated by operation, bromides, and section of the sympathetic. and 2nd, those where the disease was caused by localised peripheral injury, and here we must satisfy the indicatio causalis. If excision of the cortex did not always succeed, it was because general epileptic changes had already been set up in the brain. For fulfilment of the indicatio causalis operation should not be too long delayed. A definite judgment as to results of operation could only be given years after they had been performed.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, April 22nd, 1899.

DEATH FROM VASCULAR DEFICIENCY.

Under this title Pal has prepared a long article with experiments, to prove that death in many cases assigned to heart failure is principally due to vascular deficiency, and not to any heart impairment. The presence of a vascular tonus is generally admitted, while experiments on the vaso motor centres demonstrate the fact beyond dispute. To defend this argument we need only consult the writings of Le Gallois (1812), and

more recently, those of Goltz. When the lower portion of the cervical region is quite severed in a dog the animal does not die immediately, but the breathing will go on for some time quite spontaneously; the blood pressure gradually sicks; the arteries of the extremities become narrower, and the pulse constantly declines till it finally disappears, finally the animal sinks into a deep coma, and will probably die within 24 hours. The clinical diagnosis in such a case would be given as "heart enfeeblement," while the post-mortem bears witness that the cardiac muscle is in good condition, though greatly contracted, and containing little or no blood, while the bowel is hyperæmic.

Analogous conditions are met with in cases of hemorrhage, when the central nervous system is involved and cedema occurs. Examination of the heart during life does not reveal all changes in that organ, notwithstanding the presence of dangerous, morbid alterations, as in typhus or typhoid. Briefly stated, two conditions are present in these vascular cases: (a) Inadequacy of the heart itself; or (b) insufficiency of the supply to the heart.

His own experiments with phosphorus poisoning proved that in subacute poisoning cases the heart muscle was normal, and no degeneration present, while the vascular system was paralysed. The clinical area of the heart was small, the pulse good, but apparently the return from the vessels to the heart was deficient, as proved post-mortem.

Romberg, Bruhns, and Pässler have adduced similar testimony from experiments on animals with bacillus pyocyaneus, pneumococcus Friedlander, and the bacillus of diphtheria. In their conclusions they state that the vasomotor system must be considered in conjunction with the heart's enfeeblement.

Pal states that during the last two years he has had seven cases of poisoning from phosphorus in his wards. The post-mortem revealed a normal empty heart in four of these cases; two were not quite, though nearly empty; while one was acute poisoning, and not to be classed under the morbid effects of phosphorus changes. The two chronic cases with the heart partially filled with blood on post-mortem had been treated during life with injections of a suprarenal extract, which may account for the presence of the blood post-mortem.

The results obtained from these cases prove the existence of an enfeebled heart during life, out of all proportion to the physical signs; in many cases before death the cardiac area is decidedly less than normal, while the postmortem reveals an empty or nearly empty heart. These facts are not alone in our clinical investigations, but are analogous in many infectious diseases, as tuberculosis, typhoid, &c., as well as non-infectious, such as nephritis, pseudo-leucæmia, &c., which led to a conviction that we have a vascular death ("Gefästodes"), or death due to an impaired condition of the vessels concerned and not at all attributable to heart failure. This condition would be better described as vaso motor paralysis.

This subject has been further demonstrated on animals by drugs by Pässler, who first paralysed the vaso-motor system and subsequently by vascular stimulants stimulated the tonus. The suprarenal extract has the same power.

BALNEOLOGICAL ASSOCIATION.

The members of the Association, after a few weeks discussion, were invited by Lantin to visit his "Curanstalt," or hydropathic institution, which is one of the

finest in the monarchy. The surprised visitors were sumptuously entertained at a banquet which will long be remembered as that of the first Balneological Congress in Austria.

"PHYSICATS" EXAMINATION.

According to the recent Acts passed in January for the security of competent "physicats," the test examinations will commence this month in Vienna, followed during the year by the other universities. These examinations will consist of special chemistry, "pharmacognosia," and general hygiene.

Sanitary law is also compulsory. The examinations are written and oral.

ACCIDENT INSURANCE

Owing to the large number of accidents which the various insurance companies have dealt with since the Workmen's Compensation Act has come into force the Minister of Education has ordered that all universities teaching medicine shall devote two to three hours every week during a winter or summer session to the special study of such accidents as come under the compensation law, so that no medical practitioner will be able in future to plead ignorance of his responsibilities in this department of medicine. These additional classes must be given without any extra fee from the medical student.

The Operating Theatres.

WESTMINSTER HOSPITAL.

SUPRA-PUBIC LITHOTOMY.-Mr. DE SANTI operated on a boy, æt. 5, who had been admitted with symptoms of vesical calculus. On examination under chloroform with a sound a hard and large stone was detected free in the bladder. The boy had the usual symptoms of stone, but his mother stated he had only complained of them quite recently. The urine contained a little pus and blood. It was decided to do a supra pubic lithotomy. The patient having been anæsthetised and sounded again, the bladder was gently washed out with warm boracic lotion: then three ounces of the same lotion were injected and retained by a ligature round the penis. An incision two i nches long was next made in the mid-line well over the pubes, the fat covering the anterior part of the bladder exposed, some rather large veins hooked aside, and the anterior wall of the bladder defined. The peritoneal reflection was well seen, and was a little lower than normal the bladder was fixed with a sharp hook, and incised in. the middle line with a scalpel from above downwards. On introducing a finger into the bladder a pair of pressure forceps having been applied to each side of the viscus, the stone was felt quite loose at the base of the bladder; the calculus was very rough and large. The vesical incision had to be enlarged downwards for some distance, in order to allow of the extraction of the stone with a small pair of lithotomy forceps. The bladder was then explored to see if there were any other stones, and then gently irrigated with boracic lotion. The wound in the viscus was sutured with fine silk by Lembert's method, it was found impossible, however, to suture the lowermost part of the opening into it without unduly dragging on the bladder, so an india-rubber flanged tube was inserted into that part of the wound in the viscus, being brought out at the lowermost part of the akin wound. The upper part of the skin wound was

closed with silkworm gut, and collodion gauze dressin g applied with a peat pad over it. The stone removed weighed 500 grains, was slightly oval in shape, and measured 41 inches in its greatest circumference; it was extremely hard and tuberculated on its surface. Mr. de Santi said that the size of the stone, if for no other reason, contra-indicated such an operation as lateral lithotomy, it therefore became necessary to consider the operations of litholopaxy and supra-pubic lithotomy; he decided on the latter being the better method of operating in this case for three reasons: first, the age of the patient; secondly, the size of the stone; and thirdly, its extreme hardness. If litholopaxy had been the operation chosen, only a very small lithotrite could have been employed, and there would have been extreme difficulty with so small an instrument in crushing so hard a stone; moreover, there would have been considerable more risk of inflicting injury on the vesical mucous membrane. The operation of suprapubic lithotomy in such cases had given, he pointed out, in experienced hands extremely good results, and, with ordinary care there should be no risk of wounding the peritoneum. Where the condition of the bladder and urine permit of it complete closure, by Lembert's method, of the wound in the bladder was, he thought, the soundest treatment. In this case, on account of the rather low reflection of the peritoneum and the size of the stone, the incision into the bladder had to be prolonged downwards and the lower part of it could not well be sutured; in all cases, even when the bladder wound is completely closed with sutures, it is safer, he considered, to leave the lower angle of the skin wound open, and to keep a drainage tube in for three or four days.

WEST LONDON HOSPITAL.

INTRA-CEBEBRAL INJECTION FOR TETANUS. - Mr. BIDWELL operated on a man, æt. 35, who had been admitted suffering from acute tetanus. A fortnight before the patient had run a nail into his right foot. He had been under treatment outside the hospital, and the wound had healed. On the day before operation he could not open his mouth, and had twitchings of the right leg; he was, therefore, immediately brought up to the hospital, After admission 10 c.c. of anti-tetanic serum were injected hypodermically under the skin of the abdomen. On the morning of operation, however, the tetanus had increased, with marked opisthotonos, and the abdominal muscles were quite rigid, breathing being thoracic; it was therefore decided to inject the antitoxic serum into the cerebral hemispheres. The patient was put under chloroform, and the area of the wound in the foot freely dissected away, the scalp was then shaved and purified. The points at which the skull should be drilled were defined in the following way: -An imaginary line was taken over the head from one auditory meatus to the other, another line was taken from the base of the nose to the top of the head, crossing the first line at right angles, and a third line was carried from the outer angle of the orbit to where the first two lines crossed each other; the centre of this last line is the point where the skull should be drilled. This point was marked on the skin, and a small curved incision made just external to it, the pericranium elevated, and a hole drilled with an ordinary bradawl; the needle of the antitoxin syringe was then plunged downwards and backwards into the substance of the cerebrum, and 5 c.c. of antitoxic serum very slowly injected. This injection took about

15 minutes. The syringe was then withdrawn, and the skin flap fixed with a couple of horsehair sutures. An incision was next made at the same point on the opposite side, the bone drilled, and the antitoxin (5 c.c.) injected as before, this second injection taking 10 minutes. This wound was also closed and dressings applied. Mr. Bidwell said that when tetanus has once developed the toxin has already been fixed in the central nerve cells; these cells are not influenced by antitoxin injected hypodermically; but it has been proved that animals can be cured by intercerebral injections of antitoxin. It is well known he pointed out that hypodermic injections of antitoxin are quite satisfactory in early cases, but have proved very disappointing in more advanced ones. This method, he said, had been advocated by MM. Roux and Borrel, and about twenty cases had been treated in the neighbourhood of Paris by it with encouraging results. The first case treated in this country was by Major Semple, R.A.M.C., whose directions both for point of injection and slow method of injecting the fluid were followed in the case he (Mr. Bidwell) had just done. The reason for this slowness is to avoid breaking up the brain tissue, the object of the surgeon being to allow the antitoxin to soak in drop by drop. The object of the measurements is to select a spot where no injury can be done to any part of the motor area. He commented on the necessity of freely removing the area of the original wound, as at this point there is a colony of bacilli, from which fresh doses of toxin will be absorbed. He should continue the hypodermic injection of antitoxin daily until the stiffness had gone.

It is very satisfactory to state that the patient made an uninterrupted recovery, and left the hospital three weeks after operation.

Vital Statistics.

The deaths registered last week in thirty-six great towns of United Kingdom corresponded to an annual rate of 19.5 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year.

Birkenhead 17, Birmingham 24, Blackburn 18, Bolton 19, Bradford 17, Brighton 27, Bristol 17, Burnley 20, Cardiff 11, Croydon 14, Derby 19, Gateshead 21, Halifax 19, Huddersfield 21, Hull 19, Leeds 16, Leicester 17, Liverpool 24, London 18, Manchester 28, Newcastle-on-Tyne 17, Norwich 18, Nottingham 18, Oldham 24, Plymouth 19, Portsmouth 18, Preston 18, Salford 21, Sheffield 17, Sunderland 22, Swansea 18, West Ham 13, Wolverhampton 26. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, in Manchester; from scarlet fever, 1·1 in Halifax and in Bradford; from whooping-cough, 2·1 in Plymouth, and 2·3 in Birkenhead and in Burnley; and from diarrheea, 1·4 in Salford. In none of the large towns did the death rate from "fever," reach 1·0 per 1,000. The 59 deaths from diphtheria included 20 in London, 7 in Sheffield, 4 in West Ham, 4 in Liverpool, 3 in Portsmouth, and 3 in Leeds. Two deaths from small-pox were registered in Hull, but not one in any other town.

Mortality in Poreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Bombay 149, Madras 36, Paris 27, Brussels 17, Amsterdam 17, Rotterdam 24, The Hague 21, Copenhagen 20, Stockholm 23, Christiania 24, St. Petersburg 26, Moscow 25, Berlin 18, Hamburg 18, Dresden 21, Breslau 24, Munich 26, Vienna 25, Prague 29, Buda-Pesth 25, Trieste 30, Rome 20, Venice 37, Cairo 32, Alexandria 35, New York (including Brooklyn) 19, Philadelphia 21.

THE RADICAL CURE OF HERNIA.

THE habitual use of the term "radical cure of hernia" is probably largely responsible for the very prevalent belief that surgeons can be trusted to obviate a very disabling condition with but trifling risk to life; but, judging from a paper recently read before the Medical Society of London by Mr. Langton, the ultimate results are by no means all that could be desired or expected. The surgeon is but too apt here, as elsewhere, to consider his responsibility at an end when the wound has healed and the patient has been authorised to resume his ordinary avocation, but in such a matter as the cure of hernia it is obvious that the experiment has only begun when the patient leaves the surgeon's hands. It is of vital importance that we should know whether the permanence of the cure is such as to render it worth the patient's while to undergo the inconvenience of such an operation and the risks inseparable from a surgical intervention of this magnitude. The mortality attending the operation has steadily improved since 1880, until at the present time it is almost nil, though it must not be forgotton that the results are not equally good at all hospitals and in the hands of all surgeons. But the very freedom from danger effected by modern improvements in surgical technique may have created in the minds of practitioners a certain recklessness in advising recourse thereto, hence the importance of rendering available statistics which will show whether or not it is really a radical cure or merely an operation for the radical cure, two very different things. Unfortunately, such statistics are very difficult to obtain. Two years have been laid down as the minimum period at which it is possible to form a trustworthy opinion as to the permanence of the expected cure, and, in hospital

practice at any rate, it is almost impossible to keep one's patients under observation for this, and a fortiori for a longer, period. It appears, however, that during the last six years no less than 242 operated patients have applied to the City of London Truss Society for relief, from which it may be inferred that the total number of instances of the hernia recurring after operation in the metropolis must be considerable. It would be an interesting object lesson for surgeons to scan the list of patients thus applying for relief for this would enable them to form some idea of the success attending their intervention, and, incidentally, of the value of the particular procedure adopted by them Each surgeon has his own pet way of operating, and each, no doubt, flatters himself that his results leave little to be desired This is a delusion which it might be well to destroy, but we will not be cruel enough to advocate the publication, even among medical readers, of the list which Mr. Langton holds over them in terrorem. The paper gave rise to a very interesting debate in the course whereof various technical points were discussed, notably the frequency with which suppuration occurred in the wound and the age limits within which the operation might safely be advised. While some surgeons seldom or never witness suppuration as a complication it appears to be tolerably frequent in the hands of others. Doubtless, the age of the patients had something to do with this, for it must be vastly more difficult to obtain asepsis in the very young than in older patients. This, indeed, is a cogent argument against operation in very young subjects in the absence of urgent indications. Apart from this, suppuration is probably due in many instances to inadequate cleansing of the skin, a point which the modern surgeon might reasonably be expected to attend to. The operation, moreover, appears to be attended by small success in cases where the hernia is so large that it cannot be controlled by moderate pressure, a state which implies a large and patulous opening in the abdominal wall. Lastly the ultimate results appear to be greatly influenced by the condition of the peritoneum after operation. The existence of any fossæ or depressions must necessarily favour a recurrence of the infirmity, and surgeons understand this well enough to make every endeavour to leave the peritoneum tense and smooth, so much so indeed that the torsion of the sac resorted to for the purpose of obliterating any tendency to pouch-formation is occasionally carried so far as to drag in the bladder, a very disconcerting accident in truth. The outcome of the discussion is to leave a doubt in one's mind as to the permanent value of the so-called radical cure of hernia. The operation has, however, a recognised place in surgical therapeutics, and it cannot well be abandoned, but it behoves surgeons jealous of their reputation to study how best to obviate the insufficiencies of the procedures at present in vogue, so that practitioners may conscientiously recommend their patients to seek relief from an infirmity which entails very tangible risks and much discomfort.

MILITARY AND NAVAL SURGERY OF THE FUTURE.

THE civilised world has lately witnessed a movement in favour of peace that may well be regarded not only as the shadow of a coming event, but as one of the most notable occurrences of a notable century. The great cause of universal peace espoused by the Czar of Russia was prompted in the first place by M. Johann von Bloch, a Russian Councillor of State. In a ponderous treatise of six volumes von Bloch argues that the development of war will one day render the arbitration of the sword impossible, owing to the vast armaments, the enormous destruction of life, and the damage to commerce that must be involved. The main thesis of this epoch-making book is worked out with an elaborate detail that stamp of indefatigable energy and bears the thoroughness, and to no small extent accounts for the way in which the author has stirred up the mind of the nations. So far ar the medical profession is concerned the statements are full of interest. In the battle of the future there will be a terrific hail of artillery fire at a distance of 6,000 metres; while at 2,000 metres the bullets of the infantry will sweep the field. Already within the last thirty years the efficacy of rifles has been increased fourteen-fold, and there is no sign that the limit of destructiveness has yet been approached by the ingenuity of inventors. It seems clear that with modern arms there must be an area of at least a thousand metres between the opposing armies so swept by missiles that no man could live therein. Beyond that would come zone after zone of diminishing danger, with corresponding effects upon the human targets. The effect of the new nickel-coated, small-bore projectile is described as frightful, resembling that of an explosive bullet. It splits up bones into a mass of fragments, which tear through the body. It has a small wound of entry, and a great gaping wound of exit. It pierces three human bodies, and is stopped only by a fourth. It pulverises heart, liver, kidneys, and other internal organs, and tears muscles to shreds. At a distance of over 1,000 metres, it causes a radiated wound of entry. At 1,600 metres, it has still the power of causing dangerous, and sometimes comminuted, fractures. The natural result of all this terrific and deadly fire is that a great many more soldiers must be killed outright on the spot. Another inevitable rider is that it will be impossible for noncombatants to venture within the fatal zones, so that the wounded must lie untended during the time that the battle is waging. Delay of that kind in attending to casualties must mean a vast increase in the deathroll. Another point is that, in coming warfare, an enormously increased number of men will have to to be put in the field, which will mean that the present ambulance corps will have to be multiplied by at least tenfold. From an English reviewer's translation of Von Bloch's views we gather that "Owing to the longer range of modern weapons, ambulances must remain at a greater distance than ever from the field, and as future battles on a large

scale will certainly last longer, the wounded and dying may be obliged to remain for two or three days in the open without a drop of water or morsel of bread." In naval warfare, even under present conditions, it is impossible for the wounded to be immediately removed when a ship is engaged at close quarters, so terrific is the storm of missiles that sweep her decks. Out of all this sad desolation of human savagery issues the fixed idea of universal peace, one of the greatest conceptions that has ever seized upon the mind of man. Those who are the friends of peace have long preached an unpopular doctrine, but Von Bloch has suddenly opened to them a road to salvation. He has shown the absolute unwisdom of the nations of the earth devoting their accumulated cunning to the task of mutual extermination. He has done more for the advancement of the principle of international arbitration than any one man whose lot has been cast in this universe of unceasing upward stress and struggle towards the ideal perfection not less of the individual than of the community.

THE JUSTUS TEST FOR SYPHILIS.

To decide whether an ulceration of a given part of the body is syphilitic, tuberculous, or malignant is in some cases extremely difficult. An ulcer affecting the tongue, for example, may be either cancerous or syphilitic, and the external appearances of each disease being nearly similar in the early stages, the surgeon cannot at first be absolutely certain as to the differential diagnosis. however, an assistant in Schwimmer's clinique at Budapest, two or three years ago, designed a test which he claims will determine the diagnosis in doubtful cases of syphilis. The test depends upon the sensitiveness of the red blood corpuscles in syphilitic persons to the action of mercury administered by inunction, or by subcutaneous or intravenous injection. Justus holds that this sensitiveness is greater in syphilis than in any other disease, so much so that the administration of the drug is followed a few hours afterwards by a sudden fall in the percentage of hæmoglobin. In 300 cases of syphilis observed by Justus in which mercury was given, a sharp fall of 10 to 20 per cent. was recorded in the hæmoglobin, while among control cases, in which syphilis was not present, no such fall was noticed. The subject is fully discussed in an interesting paper by Drs. Cabot and Mertins, published in the Boston Medical and Surgical Journal for April 6th last, in which they record their own experience of the test. authors state that in the summer of 1898 they tried the test in the out-patient department of the Massachusetts General Hospital in 98 cases of undoubted syphilis, 4 cases suspected of being syphilitic, and 33 control cases of various other diseases, a total of 44 cases. From fifteen to forty grains of the unguentum hydrargyri were "inuncted" into each patient, with the result that all the syphilitic cases reacted strongly and characteristically, while in

33 control cases there was but one genuinely syphilitic In seven active positive reaction. cases the loss of hæmoglobin after one inunction averaged 21 per cent. In brief, the experiments of these two observers tended to confirm the conclusions at which Justus had arrived, with two excep tions. One was the case of a girl suffering from chlorosis. Despite the fact of the complete absence of syphilis in her, a typical positive reaction was obtained with a loss of 13 per cent. of hæmoglobin. The other was in a case of tertian ague, where a loss of 10 per cent. of hæmoglobin was noted. The latter condition, the authors believe, could be accounted for by the agueish attack occurring just after the administration of the mercury. With regard to the first case, however, the authors offer no explanation as to the cause of the loss of the hæmoglobin, nevertheless they express the opinion that so far as it goes the case certainly tends to diminish the value of the test which Justus has introduced. These experiments, however, are undoubtedly valuable, showing as they do that further investigation in the same direction might establish greater certainty as to the usefulness of the new test. That some test of the kind is needed goes without saying. If subsequent observers can prove that the Justus test is to be depended on, a distinct advance will have been made in the subject of syphilis.

Increase of Lunacy in Norfolk.

HERE as elsewhere, we hear of a steady increase of lunacy and a growing demand for additional accommodation. In Norfolk the demand seems to be more for female patients, and the County Council following the recommendations of the Committee of Visitors of the county asylum have decided to build new accommodation for males at the auxiliary asylum. The Committee of Visitors were guided to a decision by a report furnished by the medical superintendent, Dr. Thompson, who has gone into the question most thoroughly and considered not only causes of increase, but means of meeting the difficulties of the situation. He observes that the yearly increase is produced in several ways, but speaking generally it is the annual increase difference between the admissions on one hand and the deaths and discharges on the other. It is curious how unanimously superintendents of asylums write regarding causes of increase. Here again we have repeated an old tale of accumulation of senile and workhouse cases in asylums. There can be no question that patients are much too readily sent to asylums, and that their friends shunt them off whenever they become the least troublesome. Moreover, recovery rates cannot be so high when such flotsam and jetsam as senile cases, congenitally paralytics, and other incurable forms are accumulating and being sent to asylums. Moreover, as others have pointed out, the death-rate tends to diminish, owing to sanitary and other improved conditions of treatment, and here we

Essentiality of "Sanction" for an Irish Dispensary Election.

THE curious deadlock of the election of a Medical Officer of the Dundrum (Dublin) district has unexpectedly raised a question of vital interest to the Poor-law Medical Officers of Ireland. It will be recollected that, after a fierce contest between the only two possible competitors, one, who had held the neighbouring district for about twenty years, was elected by a majority of one vote. It then became known that such majority was secured by the sending of a bogus telegram to one of the voters hostile to the elected competitor, which telegram kept the voter away and turned the scale. A sworn investigation was held by the inspector of the L.G.B., and the facts were established beyond question, except that no serious attempt was made or evidence presented. to show that the elected officer had anything whatever to do with the telegram transaction or any privity to it at any time, which he indignantly denies. Under these circumstances the Local Government Board ordered a new election, but it departed from precedent inasmuch as it did not supply the guardians, as has always been done, with a precis of the facts or a statement of the reasons for invalidating the election, but confined itself to declaring that "irregularities" had occurred. The effect of this decision may be to deprive the Medical Officer of the position to which he was elected by a majority, because the constituency who are to elect on the next occasion are quite different in religion, politics, and personality from those who elected the last time, and we say that it is very hard on him that he should lose his appointment because of the offence of a third party with which it has not been shown that he was, in any way, cognizant of or responsible. The question thus arises whether the

Local Government Board has power to invalidate an election by the simple process of omitting to give its sanction thereto. Assuming that it has such power under ordinary circumstances, we do not see how it can justify the proceeding under the circumstances of this case, because, as a matter of fact, the gentleman elected has served the neighbouring district for about twenty years sans reproche. We do not, for a moment, dispute the moral right of the Local Government Board to bar the entrance into the service of a man who has disqualified himself by misconduct, but it is entirely another matter whether it can exclude a man admittedly suitable in all Needless to say that we speak in the respects. interests of justice, not having the faintest interest in either competitor.

Proposed Inquiry as to the Prevalence of Venereal Diseases.

Some time since we mentioned that a movement was being organised by a number of influential ladies who are devoted to philanthropic and rescue work among women, in the hope of inducing the Government to investigate by Royal Commission the prevalence of venereal diseases in the civil as well as the military population. Among other public bodies the organisation asked the help of the Irish College of Surgeons, and that College has responded by forwarding the following Memorial for presentation to Parliament, or to the Government authorities, as may seem best: -

The Memorial of the President and Council of the Royal College of Surgeons, sheweth-That your memorialists, having been brought into intimate relation to the treatment of venereal diseases not only in this country but elsewhere, and, being thus enabled to form a judgment as to the frequency of occurrence of such diseases in both the military and civil populations, feel it their duty to urge upon the Government the necessity for a thorough examination of the question by Royal Commission or otherwise, as may be thought best.

That your memorialists would find it difficult to

exaggerate the prevalence of these forms of disease in one or other form, and they testify from prolonged experience of both hospital and private practice that primary venereal disease is wide spread among the community, and that the dissemination of the secondary forms of the disease by these primary sources of infection is calamitous and is undermining the constitution of the nation and weakening the working capacity of thousands of innocent indialanhiv

That your memorialists, for these reasons, urge upon the Government the necessity for a thorough investigation of the subject, being fully confident that evidence can be produced by the medical profession which will convince the Government of the necessity of seeking a remedy.

We are quite certain that the great majority of our readers will sympathise with the purpose of this organisation, and with the view expressed by the Irish College, and will desire every success for the effort which these humane ladies are making.

THE Marchioness of Zetland opened, last week, the Victoria Hospital, in commemoration of the Diamond Jubilee, at Richmond, Yorkshire.

Nurses and Nostrums.

FROM time to time the fact is brought forcibly home to medical men that nurses have it in their power to work an almost endless amount of mischief among patients. With the ordinary indiscreet woman who would never learn her craft from a hundred years of training and experience we are all familiar. She tells the languid invalid with ghastly detail of all the fatal cases she has attended, she pours forth the history of her own woes, or she laughs, weeps, is lively, restless, active, still, present, absent, assertive, elusive, colourless, sharp, abrupt, decisive, inquisitive, reticent, all in the wrong places. particularly michievous minister in mind was rather she who poses as an authority on physic and matters medical, she who always knows more than the medical attendant, and is ready with an opinion upon any surgical or medical treatment, no matter how complicated or technical. Like all half-trained minds, she yearns for the specific cure, and not infrequently surrenders her belief to the blandishments of the quack medicine vendors' smoothly-worded That would not so much matter if assurances. things rested there, but, unhappily, as often as not she goes on to recommend her favourite nostrums to patients under her charge, who naturally place more trust in the advice of a trained nurse than they would in that of an ordinary layman. This evil is no shadowy one; but it may happily be believed that it is confined to a comparatively small section of a sisterhood that in its higher aspects both deserves and earns the thanks of mankind. This much may be said for their excuse, namely, that patent medicines are not unknown within the walls of our great hospitals.

The Doctor in the Witness Box.

An action was tried last week in the County Fermanagh Assizes before Chief Baron Palles, which turns a good deal on a matter of medical evidence. Mr. Thompson, a Fellow of the Irish College of Surgeons and Surgeon to the Omagh Infirmary, sued a solicitor for defamation by words spoken at an The defamatory speech repre-Orange meeting. sented that Mr. Thompson, having offered himself as a Unionist candidate for the representation of the county, and having failed, tried to "hedge" with the Nationalists, for the next election, by the evidence he gave at the trial of certain persons for the murder of a man named Funston. It seemed to be admitted that this simple murder issue was, by the religious rancour of the locality, converted into a politico-religious wrangle all the Orangemen being for the conviction of the accused and all the Nationalists for their acquittal. Be this as it may, the evidence of two or three medical practitioners who had made post-mortem examination being that the man was undoubtedly beaten to death, and that of Dr. Thompson, that he lay down and died on the roadside from natural causes, the accused were acquitted, and the defendant in this suit appears to have suggested that Mr. Thompson's evidence was influenced by his anxiety to please the Nationalist party upon whom he was supposed to be dependendent at the next election. The trial resulted

in a verdict for Dr. Thompson for two separate sums of £25. Wherever the merits of this case may be, it is, manifestly, a fact disgraceful for all concerned that a murder should be made the subject of political wire-pulling, either to convict innocent men or to protect murderers.

THE MEDICAL PRESS.

The Prevalence of Tuberculosis among Cattle.

THE announcement made some time since that thirty-six out of forty cows belonging to the Royal herd at Windsor proved to be suffering from tuberculosis on the application of the tuberculin test, the results being subsequently confirmed by post-morteni examination, is very startling, and brings us face to face with some very grave problems. It is evident that sanitation alone cannot be trusted to avert contamination, and we are told that the only effectual way of keeping herds free from this disease is to rigorously test each animal before allowing it to associate with its fellows. It has been computed that probably a third of all the adult animals in the country are more or less affected with tuberculosis, a proportion which must for the time being paralyse any effort to eradicate it from our midst. Fortunately there is no reason to suppose that the milk and flesh of cows suffering from localised tuberculosis are necessarily infective, but as it is a progressive disease it is obviously impossible to lay down any hard and fast limit, for the localised tuberculosis of to-day may become generalised to-morrow, or the disease may spread to parts, such as the udders, under circumstances which would confer infective properties on the milk and, later, on the flesh of such animals. Now that we are in possession of a means of ascertaining for certain whether an animal has latent tuberculosis it will be possible to exercise more effectual control in the matter of segregation or isolation, but in the meantime it becomes imperative to warn the public of the ever present danger of consuming uncooked milk.

Magisterial View of the New Inebriates' Act.

A HOMELESS woman, of ill repute, was last week brought up at the North London Police Court on a charge of being drunk and disorderly. It was given in evidence that she had been convicted of drunkenness five times already during the present year, and an application was made by the Court Missionary that the prisoner's consent should be asked to her being placed in a home under the provisions of the recently-enacted Act of Parliament. Mr. Fordham, the magistrate, however, held that the prisoner was not the sort of habitual drunkard contemplated by the Act. In vain the missionary pointed out that she was comparatively young and might, after a suitable period of detention, stand a chance of reformation. The magistrate laid it down that, in his opinion, the Act only applied to respectable women who had fallen victims to the craving for drink. But these so-called respectable women who are chronic inebriates, usually indulge their craving in the privacy of their homes. They do not blazon forth their ignominy by getting drunk in

public-houses and proclaiming the fact in the public thoroughfare, hence they are not likely to incur the repeated conviction which an over-scrupulous legislature has made an indispensable condition of compulsory treatment. Mr. Fordham's view, if generally acted upon, would inevitably stultify an Act which is generally recognised to be of a most beneficent character. So serious is this decision that, either by question in Parliament or by appeal to a higher court, immediate steps should be taken to have it rectified, or otherwise all the labour which this Act entailed will have been wasted, and no progress will have been accomplished in the reform of this large and distressing class of social delinquents.

No Fees.

Our legislators have not yet consented to remedy the anomaly of refusing fees to medical men for giving evidence at inquests when the subject of the inquiry has died in hospital. We have frequently insisted on the unreasonableness of this provision, which is as unjust as it is contrary to public policy, but at an inquest held last week by the Coroner for East Middlesex, the absurdity of the rule was made even more glaring. Dr. Tomlin was called in to attend an epileptic girl who had been seriously burned, and, in view of the gravity of the injuries he had her removed to the neighbouring cottage hospital, where she died in spite of every Dr. Tomlin was, of course, called upon to give evidence at the inquest, yet, on the ground that the patient had died in the hospital, his fee was disallowed. We should not have supposed that the rule would have applied in such a case, the witness not being the resident medical officer of the institution, but the coroner held that it did, and so Dr. Tomlin had to go without his fee. Why medical men, alone among members of the learned professions, should be constrained to render so many gratuitous services to Society and to the State, it would be a difficult task to explain, and it behoves them as a body to take steps to have all such anomalies redressed.

" Trailing Skirts."

A CORRESPONDENT to a morning contemporary resuscitates the objections to the fashionable "clinging and trailing skirts." Nothing, of course, could be conceived more unhygienic and uncleanly than this form of apparel. Not only do women thus become the means by which much gratuitous street sweeping is done, but worse than all their clothing gathers up, during the process, a large and varied assortment of infective abominations, which are ultimately conveyed into houses and distributed in the form of dust. From this point of view a visitor with a trailing skirt is a distinct source of danger to a household; quite possibly the infection of measles, for example, and other zymotic diseases, has thus frequently been conveyed. In this connection mention may be made of the fact that it is so usual to think only of the apparent channels of the transmission of such infection that other possible means are quite

overlooked or ignored. To suppose, however, that the fashion-mongers will ever pay any attention to what is hygienic and what is not, in their designs for dresses, is contrary to the experience of centuries. Unfortunately a "fashion" is only designed with a view to its commercial success, and this explains how it is that women have to take everything as it comes in this regard, however much they may have to suffer in consequence.

Failure of a Manchester Malpraxis Action.

THE Medical Defence Union has to add another to its long list of distinguished successes in the protection of members. The plaintiff in the action, heard last week in Manchester, was a coachman past middle age. In the course of his work he was thrown from the box of a carriage, and sustained a bad compound comminuted fracture of the forearm. His injury was treated at the Stockport Infirmary, where the house surgeon described it as the worst fractured forearm he had ever seen. Shortly afterwards he passed under the care of Dr. Gunn, of Droylsden, from whom he ultimately claimed damages for improper treatment According to the evidence of well-known hospital surgeons who had seen the arm in question, the issue of the injury was doubtful from the first. while the normal plastic operations could not be attempted from the nature of the case, and on account of the age of the patient. A radiogram figured prominently in the course of the evidence. Without hearing the address of counsel for the defence, the jury at once gave a verdict for the defendant, Dr. Gunn. As the plaintiff was unable to pay the costs of the trial, the whole of the large outlay involved in the defence would have fallen upon Dr. Gunn had he not belonged to the Defence Union. As unjustifiable "speculative" actions of this kind hang potentially over the head of every practitioner, the moral is clear, namely, to join the Association that will help them in the hour of need.

A Stupid Canard.

Some really astonishing "facts" find their way into the newspapers, and, perhaps, the most absurd thing of the kind which has come under our notice is the statement that the late Mr. Gladstone possessed a membrana nictitans in each eye, which he frequently made use of to paralyse his opponents in argument. It would be just as true to say that the present Prime Minister is able to make his opponents squirm by the aid of his vermiform appendix. How any editor could have allowed himself to be gulled by such nonsense entirely surpasses our comprehension. Every educated person should know that the membrana nictitans is only found in birds and certain mammalia. At all events, we should have imagined that, to any one of ordinary intelligence, the impossibility of any such anatomical peculiarity as that claimed for Mr. Gladstone would have been apparent at once. However, such is the gullibility of many persons that, although the statement has been absolutely contradicted, quite possibly in years to come the public will again be told that the late Mr-Gladstone had remarkable eyes, which were especially distinguished by having a nictitating membrane

Retribution.

MRS. LONGSHORE POTTS the soi-disant Yankee M.D. who has been touring this country as a lecturer on indecent subjects to women who call themselves ladies, and who has practised extensively on the vile bodies of such persons, has, we are gratified to note, been mulcted in £175 and full costs, at a trial last week in Manchester, for damage inflicted by her on a foolish, young unmarried woman. This person not only went to the lecture, but brought her sister with her, and visited the quack next day at her own house, where she was examined and frightened out of her life by being threatened with nameless evils if she did not submit to the adaptation of one of Mrs. Potts' pessaries for which, though valued at 2s.9d., she was charged £5 10s. From it she suffered so much injury that she had to go to several doctors, all of whom concurred that she had never suffered from the alleged disease, and she then brought this action We do not suppose that quacks can be prevented from trading on the erotic sensibilities of certain women, but the worst of this woman's trade is that she has been enabled to carry it on successfully because a considerable number of well-known public men, including the Bishops of Manchester, Landaff, and other places, the Lord Mayor of Manchester, an ex-Lord Mayor of Dublin, and many others lent her their names. Her ruse is an extremely clever one. Before she opens her campaign in a certain district, her agent makes a tour with her sham diploma (we have ascertained that it is not recognisable by any official authority even in America) and other documents. He calls on Bishops and other leading people, most of whom never heard of this woman in their lives, but he does not ask them to testify anything but the fact that they have seen the said documents, which statement Mrs. Longshore Potts circulates in such form as to lead the public to believe that these important individuals know her and guarantee her honesty and respectability. astounding that responsible public officials should allow themselves and their public status to be dragged through the mire at the tail of a female whose lack of medical qualification is the least of her disabilities.

The Public and Lock Hospitals.

THEORETICALLY, no doubt, the object which contributors to hospital maintenance funds have in view, is the relief of the deserving and suffering poor, though, in truth, the latter quality is the only recognised claim to medical relief. In practice, however, the great charitable public holds aloof from institutions which are, of their nature, destined to the treatment of persons guilty of the heinous offence of incontinence. It follows that hospitals for the treatment of venereal cases have always received niggardly and altogether inadequate support; and, in respect of lying-in charities, their benefits are largely restricted to women duly provided with

'marriage lines." This inopportune intrusion of Mrs. Grundy into the domain of medical charity is much to be regretted in view of the wide-spread misery and disease accruing to innocent persons from the prevalence of contagious diseases conveyed by sexual infection. The idea, no doubt, is that this very prevalence acts as a deterrent to the weakkneed and potentially incontinent, and if only the guilty suffered we should be content to leave them to their fate. Everyday experience, howevers shows but too painfully to what a great extent the innocent suffers not for, but with, the guilty. When we consider the important part which marital gonorrhœa plays in the production of tubal mischief, and the wholesale damage to generations as yet unborn caused by parental syphilis, we cannot but feel that the innocent are unjustly and unwisely made to pay the penalty for the misdeeds of others. If the public cannot be persuaded to support Lock Hospitals, the duty of providing treatment should be discharged, as in other countries, by the municipalities, especially as our general hospitals are not accessible to patients suffering from the primary disease, however grievously Why sexual misconduct should be so affected. severely dealt with while the victims of alcoholic abuse. for example, are treated with indulgence, it is not easy to explain.

Reading in Bed.

SHOULD the average man read in bed? is a query that is certain to be put from time to time to the medical adviser. A little inquiry shows that, as usual, there is semething to be said on both sides of the question. Some medical men advocate the practice as a treatment for insomnia, while others condemn it. Life is so rapid nowadays that many folk have no opportunity of seeking solace from books in their hurried passage through the hours of the working day. In such a case it is not unthinkable that a short course of some standard author taken in bed might act as a composing sedative, and lead up through easy stages of drowsiness to the deeper and fuller calm of sleep. But the book must be well chosen, avoiding all extremes of wit, melodrama, comedy, tragedy, or philosophy. It must be like a good supper, neither too heavy nor too stimulating. What is the other side of the question? Many worthy people condemn utterly and outerly the practice of reading in bed, and we think that on the whole most physicians will be found on their side. Bed was made for sleep, and healthy persons should as far as possible keep ordinary pursuits and recreations away from the bedroom, just as they take their Under conditions of moderate meals elsewhere. healthfulness a man should fall asleep soon after he assumes the horizontal posture, with a view of knitting up "the ravelled sleeve of care."

THE Council of the British Medical Association has voted, for the third time, a sum of £100 to the Jenner Society towards the expenses of the work of that society.

The Centenary of the Royal College of Surgeons, England.

THE committee appointed by the Council of the Royal College of Surgeons of England to consider the advisability of commemorating the centenary of the College have recommended that the occasion should be celebrated upon some date between March 22nd and June 30th next year. They also regard it as of cardinal importance to the success of the undertaking that power should be granted the Council to confer of honorary fellowship. The Council, however, have been advised that before this can be done a supplemental charter will have to be obtained, and accordingly the legal advisers of the college have been instructed to draft the necessary petition and charter-It has been determined to call a meeting of the "body corporate" for the purpose of submitting the question of applying for power to confer honorary diplomas to their consideration. But no date for this meeting has yet been fixed. If the charter be subsequently agreed to and obtained, we presume that the first Honorary Fellow who will be elected will be the Prince of Wales.

The Election of Examiners in the Royal College of Surgeons, Ireland

THESE elections will take place on next Tuesday, May 2nd, and the list of competitors has closed. The chief contest will arise in connection with the surgical subject. Professor Stoker and Mr. Glasgow Patteson, the outgoing examiners, offer themselves again, and in addition, Mr. Conway Dwyer, surgeon to Jervis Street Hospital; Mr. MacFeely, Mr. Pratt, also of Jervis Street; and Mr. Edward Taylor, surgeon to Sir Patrick Dun's. For the anatomy examinerships Professors Bermingham and Fraser seek re-election, and Mr. MacFeely also offers himself. For the physiology and pathology subjects there will be practically no change in the court. For the Midwifery examinership, held by Mr. Alfred Smith, there will be three additional candidates-Professor Kidd, Mr. Hearn, and Mr. Stevens, of Jervis Street Hospital. For the ophthalmology subject Mr. Benson will take, as the colleague of Mr. Maxwell, the place vacated by Mr. Story. For the courts in sanitary science and in dentistry and in preliminary education there will be no material change.

Dublin Appointments.

WE understand that, upon the resignation by Mr. Harrison Scott, surgeon to the Adelaide Hospital, Dublin, of his position as chief medical officer to Guinness's brewery, Mr. Lumsden, visiting physician to Mercer's Hospital, who has heretofore served as Dr. Scott's assistant, has succeeded to the full responsibility of the department. We learn, also, that Dr. Scott has resigned the office of medical officer to the Bank of Ireland, but no day has yet been fixed for the election. There are about ten competitors in the field, the names of Dr. Gordon, who has been acting as locum tenens, Dr. Lennon, Dr. Brunskill, and Dr. Henry Oulton being prominently

mentioned. These appointments are both of them rather attractive, for, though they entail a good deal of work and punctual attendance to business, they are fairly well paid, and they afford young men an excellent lead into private practice.

The Health of the City of London.

It is a bitter irony that in the city of London where wealth is accumulated beyond the dreams of avarice the death-rate for the last month was equal to 29.3 per 1,000 of the population, a population so small morever that there were only forty-one births which were more than counterbalanced by sixty-three deaths. The rookeries of this limited territory will hold their own with any, and however well the city may be administered in other respects the sanitation of the dwellings of the poor is evidently not a subject which commends itself to the serious consideration of its pampered corporation.

The daily press, in discussing Dr. Bra's alleged discovery of the parasite of cancer, has, with few exceptions, made a hopeless mess of the technical terms employed by this observer. We are told, for instance, that the parasite in question is a "fungas," an "assomycus," and "alga," and much of the same kind. The result in respect of the education of the public is not perhaps all that might be desired, though even if the terms had been given correctly the average reader would probably not have been much "forrarder."

An outbreak of small-pox has occurred at Hull, some fifteen cases having so far been admitted to hospital. There have only been three serious cases, all in unvaccinated persons. The inhabitants are hastening to avail themselves of the protection afforded by revaccination. It is "hoped" that the measures taken to circumscribe the spread of the disease will save the town from the loss which even a mild epidemic necessarily entails.

PERSONAL.

Mr. Lawson Tait will be one of the speakers at the meeting of the London Anti-Vivisection Society at the St. James's Hall on the 26th inst.

Mr. H. G. Howse, F.R.C.S. of Guy's Hospital, has been chosen the Bradshawe Lecturer for the ensuing collegiate year at the Royal College of Surgeons, Eng-

MADAME TERMOSHOFF, a medical graduate of the University of St. Petersburg, has taken up her abode at the Court of the Ameer in order to attend the inmates of his harem at the special request of his Majesty.

Mr. Frederic H. Madden, who for the last ten years has held the Secretaryship of the Medical School at St. Mary's Hospital, Paddington, has been appointed Secretary to the Asylum for the Education of Deaf and Dumb Children.

MR. THOS. F. CHAVASSE, of Birmingham, and Mr. F. S

Dennis, of New York, both members of the Royal College of Surgeons, England, were elected last week Fellows of the College under Section 5 of the Charter of 15 Victoria relating to members of twenty years' standing.

LORD LISTER was among the large number of friends assembled in the Mersey, on Saturday, to bid adieu to the new Governor-General of Lagos, Sir Wm Macgregor, M.D. It may be mentioned in connection with this event that His Excellency was a former pupil of Lord

SUBGEON-GENERAL J. A. MARSTON, M.D., C.B., has been selected to fill the vacancy of Honorary Surgeon to the Queen, in succession to Deputy Inspector-General Lee, deceased. Dr. Marston entered the Army as Assistant Surgeon in 1854 during the Crimean War; was present at the battle of Tel-el-Kebir in 1882, was mentioned in de-patches, and promoted Deputy Surgeon. General.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

GLASGOW UNIVERSITY -- Last week the Graduation Ceremony took place before a very large audience. The Earl of Stair, Chancellor of the University, presided, who referred in very feeling language to the loss the University has sustained in the death of the late Principal Caird, Professor Coats, and Dr. King, remarking that the University was fortunate in having secured such able successors in Professor Muir and Sir James The students on this occasion, in response to the request of their representatives, acted like reasonable beings, giving vent to their exuberance in a rational manner, so that the ceremony passed off most pleasantly for all concerned. It is needless to say that when Dr. James Finlayson came up for his honorary degree the applause was of the heartiest description. We wish him many years in the enjoyment of his distinction. It is pleasing to state that the Principal was listened to during his address with marked attention and decorum, which differed so markedly from the treatment accorded to him when he made his first appearance, when, on account of the turbulence and childishness of the students, he left the hall with his lecture undelivered. Legacies to the University of £450, £1,650, £3,064, £1,000, £500, and £18,000, for the foundation of scholarships and bursaries, were announced, and the proceedings closed with a hearty vote of thanks.

GLASGOW UNIVERSITY LORD RECTORSHIP.—The University Court has decided that the election of the Lord Rector shall take place on October 28th ensuing. this arrangement, namely, the first Saturday of the winter session, the authorities hope that the shouting and excitement consequent on the election will have ceased, and are anxious that the classes should be disturbed as little as possible. Up to the present there are no rumours of retirement on either side, and both parties have settled down with the determination to work for their side, each convinced that their candidate will be

returned.

Liberpool.

FROM OUR OWN CORRESPONDENT.]

OPENING OF THE NEW WARD AND LABORA-TORIES FOR TROPICAL DISEASES IN LIVERPOOL.

This new development of an important department of medicine reached a further stage on Saturday last, when the new ward for the reception of patients suffering from malarial and other tropical diseases, and the laboratory fitted up for scientific inquiry into their ætiology and

pathology were formally opened by Lord Lister in the presence of the Lord Mayor and a large number of distinguished visitors and leading citizens of Liverpool. Among the guests invited for the occasion there were present, inter alia, Professor Michael Foster, Professor Haffkine, Sir J. Crichton Browne, Sir Charles Cameron (Dublin), and Dr. Moore (Dublin). The ward for the reception of the cases contains twelve beds, which were already filled by patients from almost every quarter of the globe, including China, India, United States of America, Russian Finland, and Ireland. The ward, which is a handsome one, is on the top floor of the hospital building, and has a large window looking to the west, a view from it which is very extensive, and equally attractive, ombraces the magnificent river Morsey, the pride of Liverpool, and naturally of all Liverpudlians, carrying as it does on its bosom the vessels of all nations; beyond the beautiful Wirral peninsula with its crowning wooded ridge of Bidston and Stourton, and beyond this again the mountains of Wales with old Moelfama overtopping all. By the bye, a low raised platform at the west end of the ward would enable those patients who are able to sit up to lounge in their easy seats, and with their eyes take in all the beauty of the landscape before

The proceedings, which were very brief, were commenced by a short speech by Mr. Adamson, the President of the Hospital, in which he sketched the inception of the scheme and its unfolding. He said that within the past few years 460 cases of tropical disease had passed through the hospital, as many as 19 having been admitted in one day in the year 1877. He alluded to the great service rendered to the cause by Mr. A. L. Jones, who had taken the subject to heart, and done much to bring about the present issues.

He then introduced Lord Lister, asking him to declare

the ward now open.

Lord Lister said he held it to be a peculiar privilege to be invited to open the ward and laboratory. It was a distinct advantage to patients to be treated in teaching institutions There was better supervision, and when a number of eyes were looking on, and when criticism was abundant, there was less likelihood of the work being of a slipshod character than when there was no school attached. He bestowed a high eulogium on Major Ross, of the Indian Medical Service, whose services have been acquired in connection with the new school. He said his work in that special department of medicine had been of the highest importance, and had received professional recognition in France, Germany, and everywhere. He then declared the ward and laboratory open, with the wish expressed that the widest hopes of the founders would be amply fulfilled, one in which every friend of humanity will join.

MEDICAL SOCIETY OF LONDON.

Ar the meeting of the Society on Monday evening last, Mr. Betham Robinson read a paper on some complicated cases of appendicitis in which the abscess in relation to the appendix was attended later by suppuration in the neighbourhood of the liver. He remarked that this infection of the peritoneum was very liable to spread along the ascending colon when the adhesions were defective, aided possibly by the recumbent position and the natural curve of the lumbar region. He showed that the pus collected in the right hypochondrium in the space between the inferior space of the liver, the upper part of the right kidney, and the hepatic flexure of the colon, with a possible extension over the anterior and superior surfaces to form a sub-diaphragmatic collection, and he related four cases illustrating this sequence of events.

Mr. Battle referred to three cases of supposed subdiaphragmatic suppuration, remarking that these collections tracked up along the surface of the bowel and not in the cellular tissue.

Dr. Hanley mentioned a case of localised peritonitis in the upper part of the abdomen, which ultimately proved to have started from a cæcal abscess.

Mr. Macadam Eccles related a case of suppuration in the right iliac fossa, which was opened, but a subsequent

incision had to be made in the loin to evacuate another (intra-peritoneal) collection, a complication which he suggested might be forestalled by making a counterincision in the loin in the first instance.

Mr. W. Armstrong (Buxton) read a paper on the effects of the free nitrogen contained in the Buxton water on the excretion of uric acid and urea, and on the flow of urine.

Dr. Bain read a paper on "The Relative Excretion of the Nitrogenous Waste Products in a Case of Liver Abscess."

Dr. Luff confirmed the statement as to the diminished excretion of uric acid early in gout, and agreed that under certain circumstances free nitrogen might produce active effects.

Parliamentary Aews.

THE UNIVERSITY DEGREES BILL has been "blocked" by General Laurie, who announces his intention, on the second reading, of moving an amendment to the effect that the House declines to place a stigma on foreign or colonial universities by enacting that any graduate or holder of a degree of such university shall be required to add to his name the derivation thereof, while graduates in the United Kingdom are exempted from such requirements. This seems likely to prevent any further progress being made with the Bill during the present session.

THE MIDWIVES BILL, after several postponements, was adjourned till yesterday (Tuesday) when Mr. Weir was announced to move the following motion: "That no measure dealing with the question of midwifery can be considered as satisfactory which does not provide for female medical practitioners to have equal representation with men on the General Midwives Board which it

is proposed to appoint under the Bill."

THE PUBLIC HEATH ACTS AMENDMENT BILL WAS read second time on Wednesday, and was referred to a Select Committee.

THE LUNACY BILL, introduced by the Lord Charcellor in the House of Lords, was read a second time early last week without discussion. It embodies the clause for the temporary treatment of insanity suggested by the Medico-Psychological Association. It has since been discussed in a committee of the House, and Clauses 1 to 20 were agreed to. In reference to Clause 21 enjoining on County Councils the duty of granting superannuation allowances to officers and servants having charge of lunatics, the Marquis of Ripon announced his intention of opposing the clause whereupon the Lord Chancellor agreed to omit it. Clause 22 (grant of allowance or gratuity in case of injury) was also omitted. The remainder of the Clauses passed through committee, and the Bill was reported to the House.

THE ALDERSHOT SEWAGE FARM. - In the course of the discussion on the Army Estimates, Mr. Jeffreys moved to reduce the vote by £100 as a protest against the conversion of the sewage farm at Aldershot into a dairy farm for the supply of milk to the troops. A number of wellknown Service members took part in the discussion, and, after a little pressure by Sir H. Campbell-Bannerman, Mr. Powell Williams stated that if the report of the expert advisers of the War Office should cast any suspicion or doubt upon this milk supply it would be discontinued and the farm would be put to some other use. The inquiry, he added, would take place at once.

ARMY MEDICAL SERVICE. On the vote of £305,800 for the medical establishment of the Army, Dr. Clark asked whether sufficient candidates for the Army Medical Service were now forthcoming, and Mr. Powell Williams replied that there were now two candidates for every vacancy. Colonel Welby urged the War Office to consider the expediency of attaching a senior medical officer to every regiment in the country, and other members raised once again the question of the nursing arrangements for the troops at Cairo and Alexandria after the battle of Omdurman. Captain Norton, being dissatisfied with the Ministerial explanation on this subject, moved to reduce this vote, but this amendment was negatived on a division.

Obituarn.

SIR WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

THE profession has sustained a great loss in the death of Sir William Roberts, which took place last week at his residence in Manchester Square. This distinguished his residence in Manchester Square. This distinguished physician was born at Mynddygop, Anglesey, on March nysician was born at mynddygop, Anglessy, on march 18th, 1830; he was, therefore, at the time of his death in his sixty-ninth year. Having received his education at Mill Hill School, he entered at University College Hospital where he passed through the ordinary medical course, becoming a member of the Royal College of Surgeons and a Licentiate of the Apothecaries Society in 1853. In the following year he graduated at the University of London, taking the degree of M.D. Shortly afterwards he was elected to the post of house-surgeon at the Manchester Royal Infirmary, and less than two years later, at the age of twenty-five, he was appointed a physician to the infirmary. This post he held for thirty years, during which period he made for himself a great reputation as a sound, practical teacher of clinical medicine. In the Victoria University he was the first to hold the post of Professor of Medicine. In 1885 the honour of knighthood was conferred upon him in recognition of the position to which he had attained as a distinguished provincial physician. Sir William's connection with the Royal College of Physicians was especially noteworthy. He obtained his Fellowship thereof in 1866, and soon afterwards he was selected to deliver the Goulstonian lectures; again, in 1880, he deliver the Goustonian lectures; again, in 1889, he delivered the Lumleian lectures before the college, on the subject of "The Digestive Ferments and Artificially Digested Food;" and in 1892 he was appointed Croonian lecturer, giving a course of three lectures on the "Chemistry and Therapeutics of Uric Acid, Gravel, and Gout." Furthemore, in 1897, he was invited by the College to give the Harveian oration, in which he discussed "Science and Modern Civilisation." From the subject matter of the former lectures the profession 8041 subject matter of the former lectures the profession soon gathered that Sir William had made himself a specialist in dietetics, and there is no doubt that the good work which he did in this direction added greatly to his reputation. But his college, in addition to conferring upon him the honour of the various lectureships, also recognised his worth in other ways. He was appointed to the Council of the College in 1882, and in 1889-1890 he was elected one of the censors. In 1877 Sir William received the honour of election to the Fellowship of the Royal Society, while in 1879 the University of Edinburgh awarded him the Cameron Prize in recognition of his work upon the subject of digestion. In addition to other public posts he was elected the representative of the University of London on the General Medical Council, in succession to Sir Samuel Wilks, who retired on being appointed President of the Royal College of Physicians. appointed President of the Royal College of Physicians. Up to 1889 Sir William enjoyed a large and lucrative practice as a consulting physician in Manchester; in the course of that year, however, he decided to leave that city and come to London. Socially his genuine geniality made him many friends, both within the profession and outside of it. As a hobby he was exceedingly fond of botany, and in the pursuit of this he made interesting collections of various plants. Again, one of his pastimes was angling, and this he had great facilities for enjoying at his country seat in North Wales. In his long and busy life Sir William found time not only to enrich his profession with original work, but also to break away from his professional labours and indulge in pursuits which some of the wisest and best of men have made famous by the passion which they evinced for them.

MR. JABEZ HOGG, M.R.C.S., F.R M.S.

The death of this distinguished member of our profession was so sudden and unexpected that not many hours previously a member of our staff, who was an old and intimate friend, received a letter from him, written in his usual cheerful strain. Now he is no more. A painless death has closed a laborious and useful life at

the ripe age of 82, and we who have been fellow workers with him, and the readers of this journal likewise, who have from time to time perused his thoughtful and painstaking articles, both signed and editorial, will join mith that wider circle of microscopists all over the English-speaking world in the pious ejaculation, "Requiescat in pace." Mr. Hogg, before he retired some few years, was engaged chiefly in ophthalmic practice, and several books and papers on the subject emanated from his pen. For many years he occupied the post of surgeon to the Royal Westminster Ophthalmic Hospital, of which he was consulting surgeon at the mic Hospital, of which he was consulting surgeon at the time of his death. He was a vice-president of the Medical Society of London, and corresponding member of many foreign learned societies. But it is principally in connection with microscopy that his name was known; he was one of the founders of the Medical Microscopical Society, its first president, and a Fellow of the Royal Microscopical Society. But a few months since he had the privilege of passing through the Press the 15th revised edition of his work on "The Microscope: its History, Construction, and Application," a work of upwards of 700 pages with 900 illustrations. No work on the subject has we believe ever attained to such popularity, and we received a letter from him at the time testifying to the great pleasure it had given him. On Saturday last, we understand, he was busily occupied with his autographs, of which he was a well-known collector. On Sunday, without apparently anything ailing, heart failure took him quietly away to his eternal rest.

DR. WM. ALEX. CARTE.

NEWS reaches us while at press of the sudden death of Dr. Wm. A. Carte, Medical Superintendent of the Royal Hospital, Kilmainham. Previous to the occupation of his present post he was Surgeon-Major in the Grenadier Guards, Surgeon to the Coldstream Guards, and Surgeon to the Royal Hibernian Military School. He was exceedingly popular in medical circles, and will be much missed.

MEDICAL AID ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir.—I may be allowed to say, in answer to the query of "Another General Practitioner," that I am prepared to do my best to convince the General Medical Council, the British Medical Association, and other medical bodies of the necessity for taking effective steps to put an end to the medical aid work of the industrial insurance companies. I would suggest that any practitioner who possesses accurate information respecting the mode of working of these association should write either to the Registrar of the General Medical Council or to one of the direct representatives of that body. It may be of interest to "Another General Practitioner" to know that the following resolution will be proposed at the next quarterly meeting of the Manchester Medical

"The attention of the Medical Guild having been called to the methods pursued by certain industrial insurance companies, which combine medical aid work with ordinary life insurances, hereby expresses the opinion that it is inimical alike to the public weal and to the interest of the medical profession for practi-tioners to give their services to such companies in the furtherance of medical aid. The Guild is of opinion that the serious attention of the General Medical Council should be given to the matter."

As a committee of the General Medical Council is now sitting to discuss the question at issue, members may rest assured that these communications will receive full consideration.

· I am, Sir, yours truly, T. GARRETT HORDER.

Cardiff, April 22, 1899.

CONSUMPTIVE PATIENTS IN SOUTH AFRICA-A CAUTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Siz -There is a growing practice among medical men in this country of recommending consumptive patients to go to Natal and other parts of South Africa, and under certain conditions the advice is good, but there have been cases in which that advice has been followed by lamentable consequences.

In those cases where the disease is only threatened, or has become but slightly developed, and there is a reasonable prospect of recovery. provided that the patients have sufficient means of their own for their support, let them go to South Africa by all means but not otherwise.

The facts should be known that, as regards Natal (and the same may be said of other parts of South Africa) there is no provision for the treatment of consumptives otherwise than in the hospitals; that the expenses in cases of sickness are greatly in excess of the expenses in Great Britain, and that the private benevolence of the small European community is apt to be overstrained.

It is, therefore, extremely undesirable that invalids in the last stage of consumption should be sent out there to

die, or to be sent back in a dying condition.

I write this letter by desire of the Government of Natal, in the hope that by its publication in your columns medical men in this country may realise the position more clearly.

> I have the honour to be, Sir, Your obedient servant, WALTER PEACE, Agent-General for Natal.

Natal Government Agency, 26, Victoria Street, London, S.W., April 20th, 1899.

"REMODELLING OF POOR-LAW DISTRICTS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Kindly permit me through the medium of your paper to advise all medical officers, from whose districts one or more divisions are being taken in regulating the county boundaries, to at once write to the Local Government Board impressing on them the justice of so arranging the compensation that the present holders of such districts shall not suffer any diminution of salary. It seems only fair that such reduced salary for reduced work should commence with the successors of the present occupants of these posts.

I am, Sir, yours truly, F. C. FITZGERALD.

Newtownbutter, April 17th, 1899.

REGISTRATION OF COLONIAL DEGREES.

To the Editor of THE MEDICAL PRESS AND CIRCUL AR.

SIR,—A paragraph, in the report of the proceedings of the Executive Committee of the General Medical Council on February 27th last, under the heading "Colonial Degrees," deserves the attention of all colonial practitioners and also of all those interested in the higher education of women.

education or women.

In 1897 Calcutta University conferred its M.B.

Degree on a woman graduate, who was then awarded the "Elgin" Scholarship, on condition that she obtained a registerable British qualification. Finding that a registerable British qualification. Finding that women are not yet admitted to the Fellowship of the Royal Colleges of England and Scotland, she passed the examination of the Royal College of Surgeons. Ireland, and received the Diploma of Fellow in May, 1898. Application was made to the Registrar of the General Medical Council, who registered the M.B. Degree, but refused to register the Fellowship Diploma on the grounds that "A colonial qualification, can be added to a name on the General Register, as an additional qualification, but British qualifications cannot be so added

to names on the Colonial List," this is the opinion of Mr. Muir Mackenzie.

Part 2, section 14, of the 1886 Act states that the provisions of the Medical Act, 1858, shall apply in the case of colonial practitioners when registered under the Act of 1886.

This lady was registered under the Act of 1886, and therefore appears entitled to have an additional qualification added to her name on the Colonial Register under section 30 of the 1858 Act. As the non-registration of this Fellowship diploma debars the holder from appointments to which she legitimately aspires, and the Registrar informs me that similar applications have been refused on previous occasions, I have applied to the Privy Council for a direction to the General Medical Council, so that the question may be definitely decided, though, as it affects many colonial students, I should have preferred the application to have been made by the Irish College of Surgeons or the Scottish Association for the Medical Education of Women.

I am, Sir, yours truly,

CHARLES FREDERICK KNIGHT, M.D. Edinburgh, April 20th, 1899.

Laboratory Aotes.

BELLADONNA PLASTERS, B.P.

WE have received from Messrs. William Mather, Limited, of Manchester, several samples of Belladonna Plasters prepared by this firm, which we have examined, in all cases with satisfactory results. The method employed for estimating the alkaloids (which according to the B.P. 1898, must be 5 per cent. of the plaster mass), was that of C. E. Smith, as given in the Analyst of August, 1898, page 214. The plasters were found to contain 48 per cent. of alkaloid, which corresponds closely to the B.P. requirement.

There have lately been a number of prosecutious under the Foed and Drugs Acts, and as there are undoubtedly many plasters offered which do not come up to the requirements of the *Brit. Pharm.*, physicians would be wise in warning their patients to insist on purchasing only such plasters as are guaranteed to be of B.P. Strength.

EUCALYPTUS GLOBULUS OIL.

WE have duly examined the sample of eucalyptus globulus oil, "Platypus Brand," prepared by the Tasmanian Eucalyptus Oil Company, 138, Leadenhall Street, London. It possesses a pleasing aromatic odour, and is of a slight yellow colour, and on examination gave the following figures:—

Sp. gr. at 15.5 per cent., '9194; Optical rotation (100 mm, tube) +1.5°; Eucalyptol, 63.8 per cent.; Phetlandrene, absent; Alcohol solubility number, 410; Residue, 0.2 per cent.; Acidity, none.

The eucalyptol was estimated by the phosphoric acid method, and the residue by heating 10 grams. over a water bath until the weight was constant. These figures show that this oil more than satisfies the requirements of the tests given for eucalyptus oil in the latest edition of the British Pharmacopæia.

It will be probably within the knowledge of our readers that a large quantity of the eucalyptus oil of commerce does not come up to the requirements of the B.P., which, though they may be too stringent in the case of oils sold for other than medicinal purposes, should certainly be fulfilled by all oils offered for sale for such use, and the various prosecutions that have recently taken place under the Food and Drugs Act show that the question of the purity of this oil is attracting the general notice of public analysts.

Literary Aotes and Cossip.

A VERY handy little book is published by Messrs. John Wright and Co., of Bristol, labelled "Private Formulæ with Poselogical Tables." It comprises a number of blank pages with thumb index, wherein the practitioner can jot down such formulæ as he considers worthy of that distinction. A poselogical index, antidote chart, &c., serve to complete this "waistcoat pocket remembrancer."

"The Health Resorts of Europe," by Dr. Th. Linn, is described as a medical guide to the mineral springs, &c., of the Continent, but if so it was hardly necessary for the author to explain that amenorrhose signifies "stoppage of menses," or dysmenorrhose "difficult and painful menstruation." It gives useful information as to the therapeutic properties of the various waters, &c., and on the means and cost of travelling thither.

THE "Medical Officers' of Schools Association" has been well advised in reissuing, in book form, their valuable "Code of Rules for the Prevention of Infectious and Contagious Diseases in Schools" (J and A. Churchill), a copy whereof should be in the hands of everyone in any way responsible for the sanitary supervision of schools and similar institutions. The present is the fourth edition, and advantage has been taken of the opportunity to revise and complete the already ornate but practical instructions, the outcome of collective expert experience.

The "Year-book of Treatment" for 1899 (London: Cassell and Company, Limited) is characterised by Dr. Barton Fanning's article on the Open-air Treatment of Phthisis. Of the remaining articles we can only say that they are fully equal to those which for the past fourteen years have been familiar to the medical profession; and have built up the reputation of the Year-book as a convenient, useful, and trustworthy summary of the year's work in medicine and surgery.

The hon. sec. of the forthcoming International Otological Congress, to be held in London in August, saks us to announce that Baron Léon de Lenval, of Nice, has given 3,000 francs to found a "Lenval Prize," the interest on which sum will be awarded at each meeting of the Congress to the author, who evinces the most marked progress on the practical treatment of deafness. Prospective essayists are requested to apply to Mr. Cresswell Baber, F.E.C.S., 46 Brunswick Square, Brighton.

Volume IV. of the Edinburgh Medical Journal, edited by G. A. Gibson, M.D., F.R.C.P.Ed. (Edinburgh: Young J. Pentland) is now before us. The new series of our contemporary is fairly on its way, and from the excellence of the material in this, the fourth volume, the large staff of able writers associated with it, the many excellent illustrations, we have no doubt of the success that awaits it. Of the thirty-seven original articles in the journal there is not one which may not be read with interest and profit. We are glad to see the Scotch Medical School so worthly represented.

The first number of the Manchester Medical Chronicle of the new series has just appeared. New editors, new publishers, and new dress have not, however, modernised the general substance. The current number is particularly noteworthy for its numerous topographical errors. It is reassuring to read that "no attempt will be made to deal with medical politics or subjects of ephemeral or merely local interest; the journal will be conducted from a scientific standpoint." We hope that the standard of this journal will not be lowered, but that it will continue to be a trustworthy chronicle of medical progress.

THE latest issue of the "Archives Internationales de la Pharmacodynamie" is devoted to a very valuable and interesting article by Prof. T. R. Fraser and Dr. Joseph

Digitized by Google

Tillie, late lecturer on Experimental Pharmacology in the University of Edinburgh, on acokanthera Schimperi, a new heart tonic, allied in action to digitalis and strophanthus. Dr. Fraser, as is well known, has for some months past been away in India in connection with the Plague Commission, but he has certainly not neglected his pharmacological work, for the present paper is quite up to his old standard, and is a credit to the Edinburgh school. We do not know whether Dr. Tillie at present holds any official appointment, but he ought to be heard of again.

PART II. of "Aids to Materia-Medica," by Dr. W. Murrell, is devoted to drugs of vegetable origin. It, to quote the preface, consists of a considerable basis of materia-medica with a certain amount of pharmacology, as an adjuvant or auxiliary, and a dash of therapeutics as a corrective. This little volume contains all that the student could possibly be expected to know of the sub-ject, and the information is conveyed in an agreeable and convincing manner. As the subject is one that calls for much "grinding," the student can carry it about in his pocket, and dip into it as and when an opportunity presents itself.

*** "The Nursing Profession: How and Where to Train" Edited by Sir Henry Burdett, K.C.B. (London: The Scientific Press, Limited.) This is an encyclopædic guide-book for all those who are ambitious to become trained nurses, and a directory for those who have passed through that tedious ordeal. Home and foreign training hospitals and infirmaries are gazetted, described and indexed, and much useful information is given concerning preliminary training, monthly, fever, village, mental, and private nursing which will be appreciated by those for whom the book is designed.

"Norms on Surgery for Nurses," by Joseph Bell, M.D., F.R.C.S.Edin. (Edinburgh: Oliver and Boyd), as a convenient little volume is already too well known to require any examination at our hands. The rapid sale of previous editions is the best possible proof that the author has supplied a want by its preparation. In the present issue "the author has again thoroughly revised the work and added an appendix treating of the important and interesting question raised as to the Relation of the Trained Nurse to the Profession and the Public. We have no doubt whatever that it will maintain the well-deserved popularity of its predecessors.

DE. EDWARD BLAKE has done a literary tour de force in writing close upon forty pages on "The Study of the Hand for Indications of Local and General Disease" (Glaisher, London). We learn that "artistic persons usually have slender and mobile fingers," and, further, that "musical people have sensitive hands." If so, then the exceptions we have come across must be regarded as proving the rule. It must be useful to know what etiological indications we may draw from particular appearances, but when carried to the bitter end utility is obvious. For less instance. are told that petechiæ on the dorsum of the hand might be due "to the bite of a flea, to senility, scurvy, rickets, gonorhea, syphilis, small-pox, scarlatina, septicæmia, malignant endocarditis, pyæmia, jaundice, cancer, typhus, measles, albuminuria, and Hodgkins' disease, as well as many toxic agents." If a practitioner comes across petechæ on the back of the hand, we should advise him to consult a specialist, who will proceed to the diagnosis by elimination. On the whole, the monograph is disappointing, for it gives either too much or too little. It falls short of a scientific treatise, and it is too diffuse for practical clinical purposes.

Medical Rews.

French Hospital and Dispensary.

THE thirty-first anniversary dinner in aid of the funds of this institution is announced to take place at the Hotel Cecil on May 6th, when the chair will be taken by his

Excellency the French Ambassador supported by the Lord Mayor and the Sherifis of London.

Charitable Indulgence.

Some misguided testator not long since bequeathed his fortune, amounting to £11,000, to the London Homeopathic Hospital, leaving a near relative totally unprovided for. Under the circumstances the managers of this institution have decided, as an act of grace, to pay this relative £50 yearly so long as it is duly applied for, and is needed, though care is taken to repudiate any legal claims on the part of the disinherited

The Proposed Manchester Asylum for Epileptics.

A DEPUTATION from the Corporation of Liverpool recently waited upon Mr. Chaplin at the Local Government Board, to protest against the sale of the Anderton Park Estate to the Corporation of Manchester for the purpose of an asylum for epileptics, on the ground that the water supply from the Rivington watershed might thereby be contaminated. The Liverpool people are willing to take over the bargain at a reasonable price in order to obviate this contingency. The matter is to receive due consideration.

PASS LISTS.

University of Durham.-Faculty of Medicine.

At the examination held during April, for the degree of Bachelor in Medicine (first examination), the following candidates have satisfied the examiners:

Chemistry with Chemical Physics (Old Regulations). Herbert Lovis Noel-Cox, St. Thomas's Hospital.

1.—Elementary Anatomy and Biology, Chemistry, and Physics (New Regulations). Honours - First-Class

Charles Harold Crass, College of Medicine, Newcastle-upon-Tyn .

S. S. Esq.—Accidents will sometimes happen in the best regulated families, especially when authors write illegibly and proof readers are careless. We are obliged to you for calling attention to the vagaries of the printer's imp, the which we deprecate.

M. R.—You should join the Medical Defence Union and then you would have little to fear from threats of this kind, assuming, of course, that the allegations are inspired by mere malevolence and have no serious basis.

THE MEDICAL PRESS IN AUSTRIA.

THE MEDICAL PRESS IN AUSTRIA.

ONE of the vexatious restrictions on the circulation of class journals in Austria has been the sur-tax levied on each copy delivered to subscribers in any part of that Empire. Our own journal, as well as our contemporaries, has suffered for years past in this connection, the reason for which, with our ideas of a free press, seems past comprehension Fortunately, we have "a friend at Court" who has taken a kindly interest in this journal, and through his intervention we had the pleasure of receiving an official announcement last week from Vienna, stating that in future The MEDICAL PRESS AND CIRCULAR would pass as a privileged journal throughout the Empire, without any tax or restriction of any kind. We beg to tender our correspondent our most sincere thanks for his efforts on our behalf.

DR. S. J. J.—We thank you for the marked copy of the local

DR. S. J. J.—We thank you for the marked copy of the local aper you have sent. We have dealt with the matter in the current paper you have sent. sane.

PERPLEXED. - When in doubt as to the propriety of a certain step it is safer to abstain. Your plan, without being absolutely objectionable, lies on the border land. It is not enough to conform to the letter of the code which requires to be construed conscientiously, in other words, your object should be how to apply it, and not how best to evade it.

MATRON.—A medical man is not liable under such circumstances.

PACE.—Small lumps of charcoal placed inside a coffin by the side of the body will effectually prevent any unpleasantness arising from the decomposition processes.

OMEGA.—There can be no possible objection to the course which our correspondent proposes to take.

Meetings of the Societies and Lectures.

WEDNESDAY, APRIL 26TH.

HUNTERIAN SOCIETY.—8.30 p.m. Paper:—Dr. B. Harris: On the Influence of Ozone on certain Micro-organisms. Dr. T. G. Lyon will show a New Method of Ventilation by a working model.

THURSDAY, APRIL 27TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20 Hanover Square, W.).-4.30 p.m. Informal Exhibition of Cases. 5 p.m. Ordinary Meeting.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W).-9 p.m. Sir Hermann Weber: The Climates of England Compared with those of the Continent. Followed by a Conversazione

FRIDAY, APRIL 28TH.

FRIDAY, APRIL 28TH.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Clinical Evening. The following cases will be shown:—Mr. W. Turner: A Case of Achondroplasia. Mr. S. Boyd: Solution of Continuity of both Femora. Mr. A. E. Barker: Revolver Shot of the Brain through the Hard Palate, Discovery of the Bullet on the Corpus Callosum by Roentgen Rays, Removal on 69th day through the Vertex, Recovery. (To be illustrated by demonstration of lantern slides). Mr. E. W. Roughton: Tumour of the Upper Jaw. Mr. Pearce Gould: Spontaneous Cure of Recurrent Carcinoma of the Breast. Dr. A. Morison: (1) A Case of Unilateral Hypertrophy of the Accessory Muscles of Respiration; (2) A Case of False Accentuation of the Second Sound of the Heart. Mr. M. Biggs: A New Splint for Fractured Clavicle. Mr. S. Boyd and Dr. Bond: A Case after Excision of the Posterior Half of the Tongue and Epiglottis. Dr. Batty Shaw: Injury to the Roots of both Brachial. Plesuses in an Infant. Dr. N. Dalton: Pulsus Paradoxus. Dr. B. Thorne: A Case of Aortic Disease with a Musical Bruit to which "Competence" has been restored by Baths and Exercise. Mr. W. G. Spencer: A Patient after Excision of a Meningo-Myelocele, with a Skiagraph of the Condition before Operation. Mr. Battle: A Case after Removal of a Tumour of the Frontal Bone (read at meeting in March). Patients will be in attendance at 8 p.m.

BRITISH LARYSOLOGICAL, REINOLOGICAL, AND OTOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square,).—3 p.m. Cases will be shown by Dr. Dundas Grant, Dr. Milligan, Mr. Lennox Browne, Mr. Wyatt Wingrave, and others.

MONDAY, MAY 18T.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 p.m. Mr. C. B. Keetley, F.R.C.S., on "Limitation of the Gape after Operations on the Cheek and Jawa." Mr. Mayo Collier, M.S., F.R.C.S., on "Deformities of the Upper Jaw, Teeth and Palate, due to Nasal Obstruction.

- Bacancies.

Birmingham.—Assistant Resident Medical Officer at the Workhouse Infirmary. Salary £100 per annum, with spartments, rations (no alcoholic liquors), and attendance. Apply to the Clerk to the Guardians, Edmund Street.

Cheltenham General Hospital.—Assistant House Surgeon, unmarried. Salary £30 per annum, with board, lodging, and

washing.
Chorlton Union.—Senior and Junior Resident Medical Officers for Chorlton Union.—Senior and Junior Resident Medical Officers for the Workhouse Hospitals. Salary, senior appointment, £130 per annun, junior, £120 per annun, with apartments and attendance (but not rations) in the Workhouse. Applications to the Clerk, Chorlton Union Offices, Manchester. County Asylum, Shrewsbury.—Junior Assistant Medical Officer, Salary commencing at £130 per annum, with board, lodging, and washing (no liquors).

Fisherton Asylum, Salisbury.—Assistant Medical Officer. Salary commencing at £100 per annum, with board, lodging, and washing, Apply to Dr. Finch, The Asylum, Salisbury.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary £90 per annum, furnished apartments, board, coals, gas, and attendance.

Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments in the hospital.

unmarried. Centary Excepts and the control of the c and lodging in the Hospital.

Appointments.

Arnold, E. G. E. M.B., B.S.Durh., M.R.C.P.Lond., Senior Assistant Medical Officer to the Workhouse, Toxeth Park, Liverpool. Eyre, J. W. H., M.D.Durh., D.P.H.Camb., Bacteriologist to the Charing Cross Hospital, London, and Lecturer on Bacteriology in the Medical School.

JOHNSTON, T. L., L.B.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Senior Medical Officer for the Bracebridge Asylum, Lincoln. Morgan, D. N., L.B.C.P.Lond., M.B.C.S., Medical Officer to the Tonyrefail and Gilfach Sanitary District of the Pontypridd

Union.

Newsholme, A., M.D.Lond., F.R.C.P., M.R.C.S., President of the Incorporated Society of Medical Officers of Health.

Norman, F., M.D.Brux., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Eighth District of the Parish of St. Mary, Lambeth.

Norwell, J. S., B.Sc.Edin., M.B.Edin., Assistant Surgeon to the Perth Royal Infirmary.

Pearce, G. H., L.R.C.P., L.R.C.S Ed., Medical Officer and Public Vaccinator to the Fourth District of the Barnsley Union.

Reed, J. Arthur, M.B., Ch.B.Vict., Assistant House and Visiting Surgeon to the Stockport Infirmary.

Shapland John, M.A., M.B., B.S.Durh., Medical Officer to the Exmouth Dispensary.

Spencer, E. M., M.D.Toronto, L.B.C.P., L.R.C.S.Ed., Medical Officer to the Penarth Sanitary District of the Cardiff Union.

Births.

BUBNETT.—On April 19th, at 20 The Drive, Hove, Brighton, the wife of James Compton Burnett, M.D., of a daughter.

Johnston.—On April 19th, at 95 London Road, Reading, the wife of David Richmond Johnston, B.A., L.R.C.P., of a daughter.

PERARSE. On April 17th, at Ripley, Surrey, the wife of F. Edward Pearse, M.R.C.S., L.R.C.P., of a daughter.

WALLER.—On April 16th, at London Road, Stroud, the wife of A. W. Waller, M.R.C.S., L.B.C.P., of a daughter.

WHITE.—On April 22nd, at Westlands, 280 Upper Richmond Road, Putney, the wife of E. F. White, F.R.C.S., of a son.

Marriages.

LEY-MANDELL.—On April 19th, at St. Cuthbert's Church, Haydon Bridge, Carlisle, J. G. Ernest Colby, M.A., M.B.Oxon, F.R.C.S. Eng., of Malton, Yerkshire, eldest son of Wm. Taylor Colby, M.D., of Malton, to Grace Adela, third daughter of the Rev. J. H. Mandell, M.A., viear of the parish.

ANCOCK—SWEET ESCOTT.—On April 19th, at the Parish Church, Leigh, Worcester, William Ilbert Hancock, F.R.C.S. Eng., of Wiveliscombéj Somerset, to Margaret Hay Sweet-Escott, daughter of the Rev. W. Sweet-Escott, rector of the parish. ULI—WILLIAMS.—On April 18th, at Kilsby, E. H. Churton Pauli, M.R.C.S., of the Albyns, Bristol, to Clara Penelope Turville, second daughter of Dr. Williams, Guilsboro', Northampton. ARCE—SUTCLIFFE.—On April 20th, at St. John's Church, Barnsley, George Harper Pearce, L.R.C.P., L.R.C S.Edin., L.F.P.S.Glasg., to Nora, third daughter of the late H. S. Sutcliffe, Esq., of Barnsley.

To Nora, third daughter of the late H. S. Satchie, Esq., of Barnsley.

Reith—Machin.—On April 20th, at the Parish Church, Erdington, Williamson Rust Reith, M.A. M.D., Erdington, second son of Alexander Reith, M.D., Aberdeen, to Helen Constance, elder daughter of Edmund Spooner Machin, M.R.C.S., Erdington.

Beaths.

COTION.—On April 18th, at 7 Rupert Street, Hampstead, Wm. Mitchell Cotton, M.R.C.S., L.R.C.P., aged 38.

FRAZER.—On April 18th, at his residence, 20 Harcourt Street, William Frazer, F.R.C.S.I., M.R.I.A., after a long illness.

Hogg.—On April 23rd, at his residence, 102 Palace Gardens Terrace, Kensington, Jabez Hogg, M.B.C.S., in the 83rd year of his age. Kidd.—On March 20th, at Dinapore, India, Henry Alexander Kidd, M.D., late Civil Surgeon of Mandla, C.P., aged 70, of pneumonia.

MEDCALF.—On April 15th, at Church Road, Hove, Ernest Sexton Medcalf, M.R.C.S., Medical Officer of Health, Borough of Hove, aged 48.

BAYER'S

PHARMACEUTICAL SPECIALITIES.

A NEW intestinal Astringent containing 87 per cent. Tannin and 13 per cent. Hexamethylene Tetramin. A brown non-hygroscopic powder, insoluble in water weak acids, and alcohol, but dissolves slowly in diluted solution of soda and alkali. It passes through the stomach entirely unchanged, decomposition commencing only in the intestines.

THE active principle of the Thyroid Gland, combined with sugar of milk in such proportions that one part of Iodothyrine is equivalent to one part of the freeh gland. Iodothyrine contains an exactly known quantity of Iodine and always produces uniform results. Is permanent and not liable to decomposition. In this it is distinguished from all Thyroid preparations at present on the market.

THE new silver compound for the treatment of Gonorrhoea. Most strongly recommended as an antiseptic wound-healer, and as a general substitute for Nitrate of Silver. Contains 8 per cent. of silver; is easily soluble in hot or cold water; absolutely non-irritating, and possesses a better penetrating effect than any other silver preparation.

A perfect substitute for Iodoform, Odourless and non-toxic. Five
times lighter than iodoform. Nonirritating, and does not produce a rash.
Adheres closely to mucous surfaces. Of
great value in burns, its soothing and
antiseptic action rendering it specially
serviceable in such cases. A 3 per cent.
ointment is recommended.

TANNOPINE

(Hexamethylene Tetramin Tannin).

IODOTHYRINE

PROTARGOL (Proteinate of Silver.)

EUROPHEN

(Isobutylorthocresoliodide).

Has an excellent effect, without secondary phenomena, in all the various kinds of enteritis when given in doses of to 8 grains for children, and 16 grains, 2 to 4 times daily, for adults.

Has given especially good results in cases of tuberculous inflammation of the bowels, in cases of non-tuberculous, subacute, and chronic intestinal inflammation, and also in cases of typhoid.

Has been used with marked success in Myxœdema, Goitre, Cachexia, following extirpation of the Thyroid, Tetanus, Obesity, Acromegaly, some skin diseases—such as Psoriasis and Eczema—and some forms of mental affections. The commencing dose is 5 grains daily, to be gradually increased, according to results obtained. Prepared also in Tablets, each containing 5 grains.

PROFESSOE NEISSEE declares that Protargol is the best, the safest, and the quickest remedy he has yet employed in the treatment of Gonorrhosa. Protargol possesses high bacterioidal properties, and is therefore excellent for the treatment of wounds. Has been used with the greatest possible success in Ocular Therapeutics. The usual strength of the solution for injections is ½ to 2 per cent.

Put up in bougie form by Messrs. R. Sumner & Co., Lord Street, Liverpool, and R. Manson, 75, Fortess Road, London, N.W.

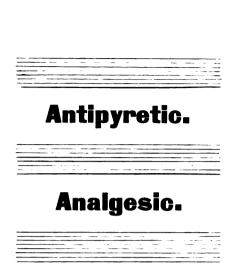

PRINCIPALLY useful in venereal diseases; in this direction it accomplishes more than any remedy hitherto tried. In cases of scrofulous, syphilitic, and varicose ulcerations a 5 per cent. ointment will befound most advantageous. May be used either pure or combined with equal parts of boric acid.

Trional, Tannigen, Salophen, Lycetol, Creosotal, Duotal, Heroin, Aristol, Tetronal, Analgen, Losophan, Somatose, Iron Somatose, Milk Somatose, Phenacetine-Bayer, Sulfonal-Bayer, Piperazine-Payer, Salol-Bayer.

Samples and Literature may be had on application to the Wholesale Depot for all Bayer's Pharmaceutical Specialities.

MALFORMATIONS OF THE KIDNEY AND DISPLACEMENTS WITHOUT MOBILITY,

WITH ILLUSTRATIVE CASES AND SPECIMENS.

By DAVID NEWMAN, M.D., F.F.P.S., Surgeon, Boyal Infirmary, Glasgow.

Anomalies of the kidney have until recently been looked upon simply as pathological or anatomical curiosities; but now that many of the diseases of the kidney come to be placed under the surgeon for treatment by operation, all departures from the normal, whether in respect of number, form, size, or situation, must be considered of moment to those who have frequently to operate upon the renal organs. The amount of literature on the subject published within the last ten years is a testimony to this.

Since early times anomalies in size, situation, and form of the kidney have been recorded, but very often only as curiosities, and little attention was given by the authors to points of detail. Recently, however, the records of cases have been carefully given, and much interest has been shown in the subject from the surgical, as well as from the pathological, standpoint.

Vesalius, Spigelius, Duretus, Valsalva, and Sylvaticus were about the earliest authors to describe the anomalies we are about to consider; since their time many hundreds of cases have been recorded, so that now we have a considerable basis to work upon.

We shall not endeavour to reconcile the various classifications of malpositions and malformations of the kidney which have been advanced from time to

If we simply study the cases recorded it will be found that they group themselves together, and may be naturally classified under the following heads:—

- A. DISPLACEMENTS WITHOUT MOBILITY: I. Congenital displacement without deformity; II. Congenital displacement with deformity; III. Acquired displacements.
- B. Malformations of the Kidney: I. Variations in number: (1) Supernumerary Kidney; (2) Single Kidney, (a) Congenital absence of one Kidney, (b) Atrophy of one Kidney; (3) Absence of both Kidneys. II. Variations in form and size: (1) General variations in form, lobulation, &c.; (2) Hypertrophy of one Kidney; (3) Fusion of two Kidneys; (a) Horse-shoe Kidney, (b) Sigmoid Kidney. (c) Disc. shaped Kidney.
- moid Kidney, (c) Disc-shaped Kidney.

 C. Variations in Pelvis, Ureters, and Blood-vessels.
- A. DISPLACEMENTS WITHOUT MOBILITY: I. Congenital displacement without deformity of the organ is by no means uncommon.

Perhaps no organs in the body vary more in their position than do the kidneys. Their relative disfrom the spine, and their position in relation to

other organs, is observed to vary considerably. For instance, without any evident cause one kidney may be found close up to the spleen, almost touching the diaphragm and the vertebral column, while the other organ is situated considerably below the crest of the ilium, and removed some distance from the spine. From observations which I made regarding this point, it seems clear that malposition of the kidney within certain limits is of frequent occurrence, and may exist without causing any disturbance. In 1,000 post-mortem examinations, 24 instances occurred where the position of one or both kidneys might be described as abnormal. In nine of these cases there was also malposition of the suprarenal capsule. Malposition of the kidney does not therefore necessarily

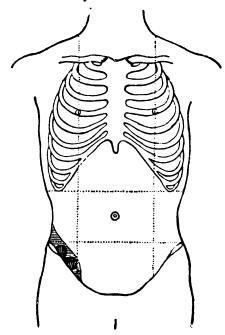

Fig. 1.

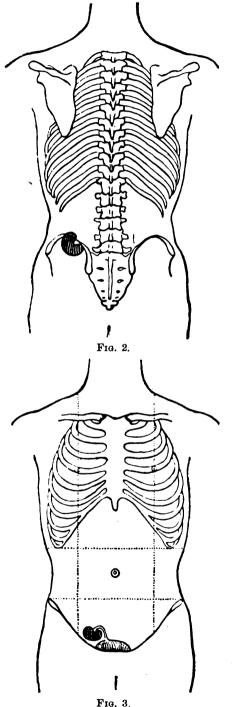

involve an alteration in the position of the suprarenal capsule, although the intimate anatomical relationship which exists between them might lead one to expect that any condition causing the kidney to occupy an anomalous position would also cause a disturbance of the corresponding suprarenal body.

CASE 1.—Fixed displacement of the right kidney above Poupart's ligament simulating a perityphlitic abscess.—Operation. (a)

The patient was admitted to the Glasgow Royal Infirmary on November 2nd, 1894, complaining of pain in the right iliac region. In September, 1890, he began to complain of pain in the lower dorsal region, but although the pain continued with more or less persistence, he continued at his work till the winter of 1893. It then became so severe that he went to bed and remained there for over a month.

(a) This case is published in detail in the Scottisk Medical and Surgical Journal, Vol. I., No. 1, p. 53.

He first felt pain in the abdomen about this time, and for six months after this he could walk about only with the aid of two sticks; the swelling in the abdomen he noticed about seven months before his admission. There was a slight fulness of the abdomen in the right iliac and lower lumbar regions, and a rounded swelling was felt passing upwards and

backwards. It appeared to be fluctuant. The dulness on percussion did not exactly coincide with the opinion formed of the size of the swelling as made out by palpation; it was obtained over an area of about two inches in breadth running parallel with Poupart's ligament. The swelling was cut down upon, and as soon as the muscles were cut through

the sense of fluctuation was lost. The incision was then enlarged, when the swelling was found to have a rounded outline with a distinct hilum towards the inner and upper aspect, and being semi-elastic but firm, immediately suggested a displaced kidney (Fig. 1).

A very thick adipose capsule was dissected through and the kidney exposed. It was quite immobile. There was no enlargement or hydronephrosis. The condition of the ureter could not be made out. The wound healed in a few days, after which the sense of fluctuation was again as deceptive as on admission.

CASE 2.—Left kidney displaced downwards and forwards in a patient upon whom lumbar colotomy was performed.

The patient was admitted to Sandyford Nursing Home early in 1897, suffering from malignant disease of the rectum, and it was resolved to perform a lumbar colotomy.

On making an incision from the lower border and tip of the last rib on the left side to a point half an inch behind the centre of the crest of the ilium, the upper border of the left kidney presented itself at the lowermost limit of the incision. When first felt by the finger in the wound, some doubt was entertained as to the nature of the hard mass; but by drawing aside the surrounding adipose tissue, the renal cortex was easily recognised. The kidney, as far as could be made out, was normal in size and form, except that

the surface was slightly lobulated (Fig. 2).

CASE 3.—Right kidney displaced downwards and rotated on its antero-posterior axis, shortened ureter

entering upper aspect of bladder.

The patient was admitted to the Glasgow Royal Infirmary in September, 1887, and died from severe abdominal injury with rupture of the liver and spleen.

At the post-mortem examination the right kidney was found to be displaced and firmly fixed, the pelvis of the kidney looked upwards, inwards, and forwards, while the convex aspect of the organ rested upon the brim of the pelvis. The kidney was normal in shape and size, and the vessels were natural in their distribution, with the exception that both the renal artery and vein were elongated, while the right ureter was shortened and entered the bladder close to the upper aspect of that viscus. The left kidney, with its vessels and ureter, was strictly normal (Fig. 3).

In the three cases above described, where the kidneys occupied abnormal positions, the fixed misplacements were not associated with any deformity of the organs.

II. CONGENITAL DISPLACEMENT WITH DEFORMITY.

The alteration in the form of the kidney seems in some instances to depend upon the situation occupied by it, as for example in a case described by M. Aubé where the left kidney was found between the common iliac arteries, close to their origin from the aorta. Pacoud narrates another, in which a kidney was found situated in the pelvis between the rectum and bladder, and somewhat similar instances have been described by Drouin, Bellini, Andral, Bonet, and others.

In my own cases, and in those referred to by these observers, alteration in form of the displaced organ undoubtedly to some extent depended on the situation occupied by it. For example in M. Aubé's case the kidney was flattened, and its anterior surface divided into three parts by two depressions formed by the passage of the two arteries. As a general rule, malpositions of the kidney are associated, particularly when the displacement is congenital, with some deviation from the normal in regard to the position of the large intestine and peritoneum, and, not uncommonly, the distribution and number of the bloodvessels, and the course and length of the ureters are found to be abnormal. Roberts states that in twentyone cases of congenital malposition of the kidney, which he was able to collect and compare, the abnormality was in every instance confined to one kidney; and the left kidney was much more commonly affected than the right (left 15, right 6). Most frequently the kidney was found lying obliquely on the sacro-iliac synchondrosis. In some cases the organ was fixed beside the uterus, or transversely between the rectum and the bladder, or across the prominence of the sacrum.

As a rule the displaced organ has its long axis vertical or slightly oblique, but it may also occupy, as illustrated by a case published by Carshaw (a), a transverse position. In this case the left kidney was found lying on the fourth and fifth lumbar vertebræ, and the long diameter was transversely from right to left, three inches. The kidney The kidney

Fig. 4.

was divided into two lobes by a fissure runanterior surface ning on the ${f almost}$ vertically. The ureter was double, one branch coming from each lobe, but these united while still in the hilum of the kidney. Two arteries supplied the kidney, one from the aorta and a second from the right common iliac, and corresponding with each artery there was a vein.

These congenital displacements will be more fully described under malformations of the kidney. At present we may give the following cases in illustra-

tion of the subject:-CASE 4.—Right kidney at the brim of the pelvis, anomalous distribution of bloodvessels, and deformity of the kidney. (b)

The right kidney was found lying on the brim of

(a) Glasgow Medical Journal, Vol. XXXI., p, 381.
 (b) Royal Infirmary Museum, Series VII., No. 2.

the pelvis. The anterior aspect of the organ is convex, the posterior surface slightly concave. The front of the organ is marked by a deep groove extending from its upper to its lower extremity. This groove is, roughly speaking, Y-shaped, the right limb of the Y being longer and deeper than the left. At the upper limit of the former an artery extensive belief and deeper than the left. enters the kidney directly from the aorta, and before entering the substance of the organ it divides into two branches of equal size. In the centre of the groove, where the two limbs of the Y join, the pelvis of the kidney is seen, and the ureter passes directly down from it. From the kidney, close to the uppermost limit of the pelvis, a large vein passes directly to the vena cava. The posterior aspect of the kidney is flat or slightly concave and is penetrated by two vessels, one a vein which passes from the kidney up its lowermost margin to the common iliac vein, and the other an artery, which arises from the common iliac artery, and penetrates the kidney at the union of the lower and middle thirds.

CASE 5.—Malposition of both kidneys, one to the right of the promontory of the sacrum, the other in the iliac fossa. Right kidney small and with no hilum. (a)

In this case the kidney was found to be situated about half an inch to the right of promontory of the sacrum, and the left kidney was discovered in the left iliac fossa two inches to the left of the sacro-iliac synchondrosis. The right kidney was small in size and so altered in shape that there was no hilum, and the ureter passed from the lower aspect of the organ. The parenchyma of the kidney was normal in appearance, and the arteries, two in number, came off from the aorta about one inch above its bifurcation. The left kidney was normal in every respect except its position. There was no evident cause for the abnormality; the other abdominal organs were practically normal, and there was no indication of inflammatory or other mischief within the abdomen.

CASE 6.—Right kidney flat, oval in form and situated at the brim of the pelvis, supplied with two arteries; one ureter from its anterior aspect. (b)

In this case the right kidney was situated at the brim of the pelvis, half in the cavity, and half out. The preparation was removed from the body of a man, æt. 61, who died of erysipelas in the Royal

Infirmary

The right kidney forms a flat oval body about the normal size. It is marked by three grooves on its anterior aspect which correspond to the line of the entrance of the blood-vessels and exit of the ureter. The organ is supplied by two arteries which pass off from the aorta in the middle line in front, just above the bifurcation. These vessels pass slightly to the right, and enter the kidney on its anterior aspect, about one-third from the upper border. The arteries lie each in a separate groove as they pass along the upper third of the kidney, and the grooves demarcate a triangular piece of the organ. The right renal vein passes to the vena cava about one inch above the level of the bifurcation of the aorta, and the vein passes from the kidney along the same groove as the arteries enter it; the ureter also arises from the anterior aspect and passes down in front and has a somewhat tortuous course to the bladder, as if it were too long for the distance to be traversed. The right suprarenal capsule is in its normal position close to the liver. The right kidney was firmly fixed in its abnormal position. No other irregularities were discovered in the vessels. The inferior mesenteric artery came off just above the bifurcation of the aorta (Fig. 5).

The left kidney was normal in size and in its relations, but it showed a distinct tendency to lobu-

 (b) Royal Infirmary Museum, Series VII., No. 1.

lation. The anterior aspect of the organ being marked by three distinct transverse grooves.

Two specimens, very similar to the above, will be found in the Western Infirmary Museum, and they

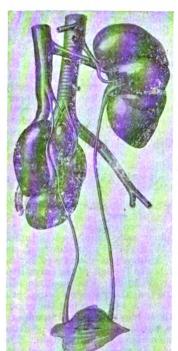

Fig. 5.

are described in a recent paper by Dr. L. R. Sutherland and Dr. G. H. Edington. (a)

In the first case the right kidney, which was found lying at the brim of the pelvis, is greatly altered in form and in rela-The postions. terior surface is flattened, showing a groove accommodating the right common iliac The artery. anterior surface shows four prominent lobules surrounding the hilum, from which the pelvis springs; the ureter is nor-mal. Two veins emerge, one on either side of the hilum, the left passes upwards in front of the aorta to empty into the left renal vein,

while the right empties directly into the inferior vena cava. The right kidney is supplied by two arteries which arise separately from the anterior aspect of the aorta, and

pass in grooves to the upper part of the hilum (Fig. 6). In the second case the right kidney was found at the level of the bifurcation of the aorta, and to the right of that vessel. In this case also the hilum is situated anteriorly; and the bloodvessels, three in number, arise directly from the aorta. The veins unite to form a common trunk, which empties into the vena cava above the junction of the common iliac veins.

The pelvis is bifid, and the two limbs pass from the kidney at different levels, the left one being the higher. The ureter comes from the lowermost limit of the united pelvis. It passes downwards and inwards, lying in a shallow groove on the anterior surface of the lower lobe (Fig. 7).

These remarkable cases of malposition of the kidney seldom give rise to serious symptoms, and generally escape observation during life.

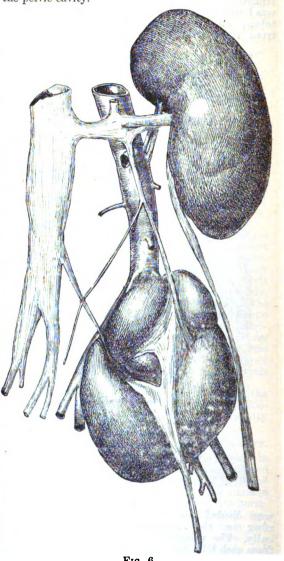

Cases, however, have been recorded where the misplaced kidney has been mistaken for an abdominal tumour, or, in the female, has from its position in the pelvis become a serious obstacle to parturition.

III.—Acquired Displacement of the Kidney.

Besides being liable to congenital malposition the kidney may be displaced upwards, downwards, or laterally from the enlargement of other organs, such as the liver, spleen, suprarenal capsule, or pancreas, or from the pressure of tumours near them. When the right kidney is depressed by an enlarged livernot an uncommon accident—it is most usually rotated on its short axis, the hilum is turned downwards, and the upper portion of the kidney is more depressed.

(a) Glasgow Medical Journal, February, 1898.

Rayer mentions an instance where the right kidney was forced down by an enlarged suprarenal body, and cites a case of Hohl's where the kidney, situated deeply to the inner side of the psoas muscle, offered an obstruction to parturition by retarding the passage of the child's head; Laennec also describes a case in which the right kidney was pressed downwards to the opposite iliac crest by a greatly enlarged liver, and Morris mentions an instance where the left kidney was depressed on to the brim of the pelvis by a large cyst in its lower part, which contained a pint of yellow fluid. The cyst had dragged the kidney down, and itself occupied the greater part of the pelvic cavity.

F1G. 6.

Case 7 .- Acquired displacement of the right kidney by a perinephric abscess.

In a case of perinephric abscess upon which I operated in 1890, on opening the abscess by a lumbar incision, after the pus was evacuated, great difficulty was experienced in finding the kidney. By enlarging the incision upwards, the kidney was discovered with its convexity looking upwards, and lying close to the diaphragm, while the pelvis was turned downwards. The kidney was quite danield of adipose tissue so that its contour could denuded of adipose tissue, so that its contour could be easily made out, the organ was firmly fixed in its abnormal position, probably by inflammatory

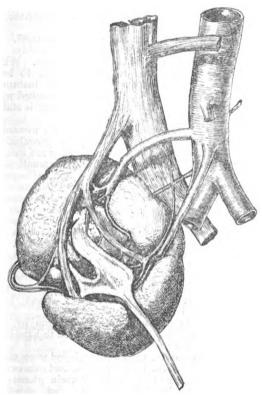

adhesions, and, as far as could be discovered by examination with the finger, the upper border of the kidney was resting on the vertebræ, while the renal bloodvessels and ureters must have been elongated.

Many similar cases have been recorded where the kidneys have been displaced in one direction or another and anchored by their vessels and ureter. The displacements naturally cause rotation of the organ in its short axis.

Probably the most important fixed displacements, either congenital or acquired are those where the kidney comes to occupy the cavity of the pelvis, or where the organ is placed in such a position as readily to be

mistaken for an abdominal tumour.

When the kidney had been displaced and occupies the cavity of the pelvis, the swelling may possibly be made out by a rectal or vaginal examination, but in

F1G. 7.

all cases the diagnosis is extremely difficult, as in many instances the organ is not only displaced but also malformed, so that the normal reniform outline is lost as a guide in diagnosis. When, however, the normal shape is maintained it is an important aid to the diagnostician, and when superadded to the presence of a reniform swelling in an abnormal situation there is a loss of the usual fulness and resistance in the loin, a suspicion of misplacement of the kidney may be aroused.

Fixed malpositions of the kidney have seldom been diagnosed, as they almost never give rise to symptoms or even to inconvenience during life. Up to the present time most of these anomalies have been discovered after death, but now that operations upon the kidney are of frequent occurrence, the clinical aspect of the subject is likely to be more fully

recognised.

(To be continued.)

Dr. VIDAL, of Perigeux, has been awarded, by the Paris Society of Biology, its annual prize, for essay on the influence of chloroform on nutrition.

ON THE PLAGUE. NOTES

COLLATED

By SIR CHARLES A. GORDON, K.C.B., M.D., Surgeon-General (retired), Hon. Physician to Her Majesty the Queen.

(Concluded.)

15. STAMPING OUT.

ALTHOUGH there was no epidemic, Dr. Hossack denied the inference that the measures adopted were sufficient. He believed that there was a factor in the environment of Calcutta inimical to the spread of the plague. The form of the factor was unknown. At Bombay, Major Boughton was of opinion that so long as overcrowding increased, and subsoil water and bad drains existed, the disease would never be exterminated. At Belgaum plague died out spontaneously in September, although the place was neither disinfected nor evacuated. In the latter days of March, 1899, the statement was made with reference to the Indian epidemic that as yet the efforts to stamp out the plague have not met with the success due to the devotion of the officials.

16. NATIVE OPINION.

Dr. Bose stated that in the northern portion of Calcutta only could disinfection be carried out, elsewhere it was impossible, being repugnant to the people, who looked upon it as injurious to health. The natives objected to inoculation. He induced a few men to be inoculated; they were looked down upon by members of their caste. Both Mahomedans and Hindoos objected to corpse inspection, even in the case of males.

Dr. Hossack said that the people gave false informa-tion regarding plague, or refused it. The people had the greatest abhorrence of the plague measures and officials. This sentiment was mixed with a considerable amount of political feeling. The native doctors with Indian degrees rendered no assistance, but resisted the action of officials and concealed cases. Dr. Banerjee thought that native doctors did render assistance. But he admitted that there was some

difficulty in getting information.

Surgeon General Harvey said that the natives objected to inoculation because mutton was used in the preparation of the fluid. The principal necessity in inoculation was to overcome the prejudices of the natives with regard to European medicines. Mr. Winter said that in the Hurdwar towns the natives preferred corpse inspection to segregation. Colonel Adams stated that segregation and detention were less objectionable to natives than disinfection by chemicals or house visitation. Captain Grant said that in the Agra district all treatment was refused by the natives who feared poison, the people concealing cases owing to their aversion to going into camp. Lieutenant Niblock, at Kurrachee, said the removing of patients to hospital frightened them, and sometimes reduced their chances of recovery 50 per cent.

At Kolaba there was some resistance to the plague measures in the first epidemic; there was none during the second. No objection was made to corpse inspection.

SUMMARY AND CONCLUSIONS.

In the preceding articles an endeavour has been made to collect and arrange such information regarding the plague in India as appears in the columns of the Times and other newspapers. From the summary so presented the following conclusions appear to be justified, namely

1. Plague in India, 1896-99, is said by some reporters to be a recurrence of Mahamari or Pati plague, by others not to be so. The forms and degrees of the present epidemic vary, in some instances mani-

festing characters of malignant endemic fevers; in others, of influenza. Cases of plague are stated to have been, in certain instances, recorded under other headings, statistics being thus vitiated.

2. On the one hand, the disease is described as being endemic; on the other, as imported. Endeavours were made by some reporters to connect the disease with particular geological formations and

with the vicinity of rivers.

said are to 3. Attacks of plague most frequently at night. By some reporters males are said to be more liable to them than females; the most general age from twenty to forty; by others that sex and age make no dif-ference. In certain instances herdsmen are said to have been relatively exempt; Hindoos to have suffered more than Mahomedans; in others, Mahomedans more than Hindoos, and native Christians to a great extent. According to other reports, the incidence of the disease is equal among all races.

4. Outbreaks of plague occur at different places in each month of the year; thus there is no relative

seasonal difference in that respect.

5. A recognised expert gave his opinion that a patient does not die of plague because he has bacilli in his blood, or recover because of their absence. Thus the presence or absence of such organisms becomes without value for purposes of prognosis. The germ said to be special to the malady is declared to be incapable of living in sewers; light to be unfavourable to it. Certain observers found bacilli in all cases examined; certain others failed to find them in In some instances where they existed they were variable and degenerate in size and shape.

6. The spread of plague was assigned respectively to clothes, goods, human agency, including travellers by road, rail, and sea; to windborne germs, to germs entering by abrasions, to grain, to animals, including fleas. Other reporters were unable to find the original source of infection, or relation of infected cases to each other. In Calcutta some native men employed in post-mortem rooms became affected, but neither nurses nor other ward attendants, nor friends visiting patients. Of persons living in the same house some

remained exempt, while others were affected.
7. The possible transmission of plague by means

of water or milk is not alluded to.

8. Diffusion of the epidemic was by some reporters assigned to rats; they observed also that in certain places monkeys and squirrels, in addition to those animals were contemporaneously affected. In one instance, dead rats were absent during an epidemic, their influence was accordingly doubted. In another, rats were the only victims, human beings not being affected. At one place mentioned, squirrels and cats suffered, the latter animal believed to have transmitted plague to man. Fleas, as transmitters of infection, have been already mentioned.

9. Several kinds of anti-plague liquids are said to have been used the mode of preparing one only is given so far. In various examples of that liquid impurities, including pathogenic organisms were found. Another such liquid is described as useless. Experience gained on unimals was not always verified on man. It was proposed to treat cases in hospitals by means of serum, and by ordinary methods respectively, also, to mix and average serums from different houses. So far, then, mistrust in the utility

of the several liquids in use is implied.

10. Opinions of reporters differ in respect to the protective and curative properties respectively, assigned to inoculation against plague. Adverting to success claimed for that method the statement occurs that no one can say whether persons inoculated would otherwise have been attacked. Some Some reporters stated that the method reduced mortality by tion, must as in the past, be subdued before or pari plague. Others that it did not confer immunity to passu, whilst we attack the bacterial cause of them

the extent supposed, that the results from it were negative, that in pneumonic cases it failed, that in some instances plague occurred in persons inoculated, while those uninoculated remained unaffected. certain places inoculation was supplemented by stimulants and by other means. In certain other places other means were found satisfactory to the exclusion of inoculation. The practice was but a makeshift, it could not take its place among the great sanitary laws.

11. Among methods of treatment mentioned were neem (melia azadarichta) and olive oils, red iodide ot mercury, Baroda pills, and alcoholic stimulants, &c. On the one hand, the statement occurs that patients treated did better than those untreated. On the other, that no curative agents were beneficial, that no On the

treatment stopped the disease.

12. In some instances segregation of patients was said to be successful. In others it was described as

a mistake, and had to be abandoned.

13. Disinfection by various means was used. In some instances they were reported on favourably. In others they were impossible, or were evaded. When employed, they were said to be inefficient, to have been opposed by the people. In some instances inhabitants of houses disinfected were attacked with plague on returning to them. The practice is stated to have been abandoned.

14 It is said that in combating plague, measures of sanitation should be placed before inoculation. Superior sanitary conditions of Europeans are said to have preserved them from attack. Evacuation of infected places where practicable resulted in decrease of the disease in those places (by reason of diminished numbers to be attacked). In large cities the measure was impracticable. Municipal camps had varying degrees of success. In Bombay, and certain other places, epidemic plague recurred on several occasions after all sanitary measures had been applied. A British regiment became affected notwithstanding its superior advantages in that respect. In various instances the sanitary methods employed resulted in the people concerned being left houseless for the time being. In others, the epidemic ceased, irrespective of such measures.

15. All efforts to stamp out the plague by the several methods described are considered to have been

ineffectual for the purpose.

16. Protests against methods employed were made by the people concerned, in the Press, and otherwise; armed demonstrations occurred in certain places; in others, the people left infected towns, their object to avoid those methods. Some of the demonstrations thus alluded to were, in the first instance, connected with the bearing of measures in question on usages of religion and caste; there is reason to believe that to these political opinions became superadded.

NOTE ON PROTARGOL IN URETHRITIS. By JAMES MACMUNN, M.R.C.S., L.R.C.P.Lond.

In reading the criticisms of other surgeons on the employment of this drug I find that although they often particularise their mode of treatment they fail to dwell on some important considerations, and on accessories to treatment by injection, without which

no drug can have fair play.

Chief among these are the stage and degree of inflammation present, and the mode of injecting.

Guided by this recent literature a novice would have no qualms in applying this new remedy in the presence of the most severe inflammation attacking any part of the urethra. This would be a great mis-take, even with protargol. Inflammation and irrita-

by rest, aperients, and certain internal means and external applications. I cannot help alluding to the good effects of lead lotion constantly applied in penile urethritis and rectal douches in deep urethritis.

Then, as to injections, these are best carried out by a special aseptic syringe made for me years ago by Messrs. Arnold and Sons. With it the patient cannot hurt himself, and its peculiarly-shaped nozzle allows of the prolonged retention of the solution,

owing to the way it plugs the meatus.

I have found protargol most excellent, not only in anterior, but also in deep urethritis. Nitrate of silver was, up till lately, the almost indispensable salt for the latter, but its property of combining with albumen, and in this way actually forming protection shields for the deep-seated gonococcus, greatly detracted from its value. Now happily we possess a drug of superlative value devoid of such effects.

In urethritis I begin with ‡ per cent. solution. deep chronic urethritis I often instil a 5 per cent.

solution.

THE ATTENUATION OF SYPHILIS IN PORTUGAL IN 1812.

By GEORGE OGILVIE, B.Sc., MB.Edin., M.R.C.P. Lond.,

Physician to the Hospital for Epilepsy and Paralysis, Regent's Park, London.

Dr. John A. Shaw-Mackenzie's peace of mind has of late been repeatedly disturbed by several of my papers having been—to use his own words—"prominently noticed," and having received "considerable support" in the leading medical journals of this country. Much as I regret the discomfort which this has caused him, I cannot but feel gratified by the fact which has given

A notice in the Lancet of January, 1898, on a paper of mine drew forth his first letter; a leading article in the British Medical Journal for November, 1898, on "Syphilis in the Army," was promptly followed by a lengthy letter from Dr. Shaw-Mackenzie's pen; and now the short notice which appeared last January in the MEDICAL PRESS AND CIRCULAR on the same subject has again aroused him to action. This time his reply (vide MEDICAL PRESS AND CIRCULAR, February 22, March 1) occupies not less than eleven columns. Of course, it is impossible to fully answer an attack so formidable by its length, within the space which could be allotted to me for the purpose; but I would like to draw attention to a few inconsistencies in his remarks. I should have done so before had I not had to ask Professor Neumann, of Vienna. for some information on a certain point which I shall have to refer to later on. Hence the delay.

Dr. Shaw-Mackenzie's attempt to "represent the work of Fergusson in its proper light" is a Quixotic adventure He is fighting for a chimera, viz., the attenuation of syphilis in Portugal in 1812, which cannot be substantiated by a single fact, which is not sustained by a single writer of competence, and which has been repudiated by Fergusson himself. Among the numerous surgeons, the evidence of whom I have collected, there is not one who, from his own personal experience, reports attenuation. Dr. Shaw-Mackenzie, with an air of profound erudition, says:—"But he (Dr. Ogilvie) does not mention Hennen, an equally prominent Peninsular surgeon, who, while subscribing to the non-mercurial treatment, thinks it 'proper to direct attention to the opinion of those who held,' like Fergusson and others previously, that syphilis has 'undergone great previously, that syphilis has 'undergone great changes in its nature since the end of the fifteenth century.'" What is there in this quotation worth mantioning? Hence it was the control of the worth mentioning? Hennen does not report his own experience, he only directs attention to the opinions of others, and these opinions only refer to changes in the nature of syphilis as compared with the disease at the end of the fifteenth century. But the question with Fergusson Abolitionismus," he thus expresses himself: "Only those was not whether syphilis in Portugal in 1812 was milder who form their opinions in a most perfunctory manner

than syphilis in the fifteenth century, but whether Portuguese syphilis in 1812 was milder than English syphilis in 1812. As a result of Fergusson's personal experience in Portugal it certainly appeared to be so, but his experience was not of a kind to decide the question. Later on, when he thoroughly realised that the severe character of English syphilis was due to aggravation by "murderous and unnecessary courses of mercury, then the inevitable conclusion he arrived at was that the comparatively milder character of Portuguese syphilis could not be attributed to attenuation. This is sypnins could not be attributed to attenuation. This is the reason why Fergusson's later paper "makes no mention of attenuation." Dr. Shaw-Mackenzie's prophetic suggestion that "six years later, even had he lived, Fergusson again might have had reason to revert to his original opinion" can hardly be taken seriously. But the fact remains that Fergusson, whom Dr. Shaw-Mackenzie so relightly defends against himself totally Mackenzie so gallantly defends against himself, totally abandoned his self-attenuation theory of syphilis, finding that there was not a tittle of evidence to support it.

It has been somewhat of a surprise to me to read that "in proof of the truth of Fergusson's views the similarity of the aggravated form of disease among British troops invalided home from India was originally adduced" by Dr. Shaw-Mackenzie. Until he quotes chapter and verse I am bound to consider this statement the production of a daring imagination, a fiction, "all carved from the carver's brain." I have only to add that when this "similarity" was first pointed out by me it was not done in "proof of the truth of Fergusson's views." This could not have been done seriously and

reasonably by any one.

Of Dr. Shaw-Mackenzie's exegetical abilities I will give only one example, which is at the same time amusing and characteristic. In his text-book on syphilis Professor Neumann on two occasions states that he is not in a position to corroborate Fergusson's statement about the particularly benign character of syphilis in Portugal, while in his historical introduction to the same book he declares, that syphilis is particularly benign in Portugal, and that therefore he is in opposition to Fergusson who "pointed out the malignancy of syphilis in Portugal." This latter statement, I said, was evidently a slip of the memory on Neumann's part. On this point Dr. Shaw-Mackenzie, however, becomes very suggestive and deep, or rather abstruse. He says: "Among 'the well-known facts of Fergusson,' his notice of the 'very severe' disease in Lisbon among the Portuguese is referred to. Professor Neumann's later opposition to the 'malignancy(?) of syphilis in Portugal' is, probably, not 'evidently a slip of the memory excusable in so bulky a work,' as Dr. Ogilvie thinks, but founded on the statements of Fergusson, corroborated by Guthrie." I therefore wrote to Professor Neumann and asked him for an explanation. He has kindly replied that the statement in the historical introduction to his book is due to a misprint, which at the time my letter arrived had already been corrected for the second edition of his work. Risum teneatis, amici?-Rideret Fergusson. What a curious malady it must have been that he observed in 1812, this "very mild," "very severe," "attenuated," "malignant" syphilis "among the Portuguese."

If Dr. Shaw-Mackenzie is not altogether successful in the interpretation of the authors he quotes, he is still more unfortunate in the choice of his authorities. Formerly it was Aitkin's misstatements which were produced as final and crushing "testimony." Of late Dr. Shaw-Mackenzie's piece de resistance has been a com-Shaw-Mackenzie's piece as resistants in the munication made by Professor Tarnowsky, of St. Petersburg, at the last International Congress of Dermatology, while in the "majority" of relating to thirty cases of syphilis, in the "majority" of which both parents and children had acquired syphilis. Elsewhere I have shown that these observations do not in the least prove the attenuating influence of syphilis. Perhaps Dr. Shaw-Mackenzie would have hesitated to place himself under Professor Tarnowsky's protection if he had known the, by no means flattering opinion in which this author holds the adherents of the attenuation theory of syphilis. In his book, "Prostitution and Abolitionismus," he thus expresses himself: "Only those or who are utterly ignorant of medicine, can at the present day speak of attenuation of syphilis as a pathological process." Herbert Spencer once said that, "without going the length of Mr. Carlyle, and defining the people as twenty-seven millions mostly fools, one will yet confess that they are but very sparely gifted with wisdom. In the same way, "without going the length," of Professor Tarowsky, "one will yet confess," that those who, like Dr. Shaw-Mackenzie, proclaim that "the question of hereditary immunity and attenuation is absolute fact," are "but very sparely gifted," with discernment and knowledge.

Sed hac hactenus! In conclusion, I have one practical suggestion to make to Dr. Shaw-Mackenzie in exchange for the many theoretical ones contained in his paper. In my first paper I had by mistake spelt Fergusson's name with one "s" only. Heu misero mihi! But: solamen miveris socios habuisse malorum. The same mistake is made by Dr. Aitken, Mr. Hutchinson, and, not last but first, by Mr. Henry Lee. Whenever Dr. Shaw-Mackenzie quotes from my first paper he makes it a point to place an alarming "sic," in brackets after "Ferguson" while he does nothing of the kind when he has to quote the same mistake from other writers. If this mode of procedure is not exactly fair, there is a certain air of juvenility about it which renders it quite pardonable.

Dr. Shaw-Mackenzie tells us that "not long before his lamented decease" Mr. Lee "gave him permission to make use of or even alter any of his writings." This is certainly a most extraordinary testamentary deposition on the part of an author of original thought and personal experience. Should Dr. Mackenzie ever make use of this right it would be advisable not only to correct the spelling of "Ferguson's" name, but also to "alter" the conclusions drawn by Mr. Lee—and religiously espoused by Dr. Shaw-Mackenzie — for they were "obviously founded upon imperfect knowledge" of Ferguson's work.

Clinical Records.

WESTMINSTER HOSPITAL. Hysteria or Hemiplegia? Under the care of Dr. MURRELL.

AMELIA B., æt. 22, unmarried, was sent up from the country as a case of supposed hysteria, for which she had been extensively blistered in the ovarian regions. Three months ago, whilst in her usual health, she suddenly lost power all down the right side, and was insensible for several days. On regaining consciousness she spoke indistinctly, and was unable to move the right arm or leg. She gradually improved and little by little the power of movement in the limbs returned. On admission it was noted that she presented none of the ordinary indications of hysteria. The right arm and leg were distinctly weaker than the left, although the paralysis was nowhere absolute. Her gait was hemiplegic, and she dragged her right foot slightly in walking. Her right arm and foot were warmer and moister than on the healthy side. The right knee-jerk was more on the healthy side. The right knee-jerk was more marked than the left, there was ankle clonus on the right side only, and the right plantar reflex was exaggerated. There was right-sided hemi-anasthesia of the face, trunk, and limbs. The patient had no idea that her sight was affected, but she was blind in the right half of both visual fields, the hemiopia being absolute. The optic discs, the pupils, and the external ocular move-ments were normal. There was no heart mischief, and there was no albumen in the urine. Menstruation had entirely ceased since the attack. The family history was good, with the exception that one brother and one sister were deaf and dumb. The patient had had no previous attack or seizure of any kind.

Remarks by Dr. Murrell.—To overlook a gross lesion of the nervous system and to attribute the symptoms to hysteria, is as bad a mistake as can be made. In this case there is not a single symptom pointing to the existence of hysteria. The disease is organic and not functional. In every case of organic brain disease

there are two questions which have to be discussed—

1. What is its situation? 2. What is its nature?

The position of the lesion is determined by the objective

symptoms, and all that is required for its localisation is a practical acquaintance with the anatomy and physiology of the nervous system. The nervous system the anatomy and is a combination of an immense number of units called "neurones," each composed of a cell-body, of proto-plasmic processes or "dendrites," and of the axis-cylinder process or "axone." A voluntary motor impulse starting from the brain cortex must pass through at least two neurones before it can reach the muscles, and we accordingly speak of the motor tract as being composed of two segments, an upper and a lower. The upper neuron extends from the motor cortex down through the corona radiata, internal capsule, and pyramidal tract to the dendrons in the anterior horns of the spinal cord on the opposite side. The lower neuron commences at the anterior cornual cells, and extends through the anterior nerve root along the motor nerve into the motor end organ and the muscles. The upper neuron exerts a restraining influence on the lower, and checks the overflow of nerve energy which proceeds from the lower neuron and produces their "tone." If one part of a neuron is injured the whole neuron suffers. If, for example, the cortical cell is injured the axis-cylinder process or axon also suffers and undergoes degeneration. In the same way if a motor nerve is injured the functions of the cortical nerve cell are impaired. If the upper neuron is damaged it can no longer exert its restraining influence on the lower neuron, so that the tone of the muscles is raised and we have exaggeration of the deep reflexes. If the lower neuron is injured the corresponding muscle fibres lose their tone and undergo degeneration.

Lesions of the motor tract may be divided into two great groups, those of the upper neuron and those of the lower neuron. A lesion of the motor tract, whether of the upper or the lower neuron, will produce motor paralysis, but the type of the paralysis differs in the two

cases.

Motor paralysis due to a lesion in the upper neuron is characterised by:—1. Motor rigidity. 2. Increased deep reflexes. 3. Absence of muscular atrophy. 4. Normal electrical reactions.

Motor paralysis, due to a lesion in the lower neuron, is characterised by:—1. Flaccidity of the muscles. 2. Diminished deep reflexes 3. Muscular atrophy. 4.

Electrical phenomena of degeneration.

Applying these considerations to the case now before us we have no difficulty in determining the site of the lesion. Absolute hemianopia, slight hemianæsthesia, and slight hemiplegia, all on the right side, point to a lesion of the left internal capsule, the knee-shaped band of white matter which is bounded on its outer side by the lenticular nucleus, and on its inner side by the optic thalamus and caudate nucleus. The lesion is probably far back where the fibres of the optic radiation are found behind the sensory tract.

The determination of the pathological nature of the lesion is a much more difficult matter, and in the elucidation of this problem we must be guided to a very great extent by the history of the case. A sudden onset indicates a vascular lesion, while a gradual onset points to an inflammatory condition or to a new growth. Our patient was attacked quite suddenly so that we have no hesitation in saying that the lesion was connected with some disturbance of the blood supply. The common vascular lesions are (1) Embolism. (2) Thrombosis, and (3) Hæmorrhage.

In embolism we have:—1. An absolutely sudden onset. 2. No unconsciousness. 3. A mitral murmur. In this case there was the sudden onset, but the other indications were absent, so that we may put embolism out of court.

In thrombosis we have:—1. A gradual onset. 2. Unconsciousness rare. 3. Arterial disease such as atheroma or endarteritis of syphilitic origin. 4. Blood pressure at time of seizure low; may occur during sleep.

In this case the onset was sudden, and unconsciousness was of profound duration, so that this cause may be eliminated.

In cerebral hæmorrhage we have:—1. Onset less

sudden than in embolism. 2. Unconsciousness. Arterial degeneration probably associated with Bright's 4. Blood pressure at the time of seizure, high;

often following excitement or exertion.

The onset was This fits in closely with our case. certainly sudden, how sudden we do not know. There was prolonged unconsciousness, and there was probably high arterial tension due to the absence of the menstrual function. Cerebral hæmorrhage, it is true, is not very common in young women, but many such cases are recorded, and it has even been noted in children. From a consideration of all these circumstances I think we are justified in concluding that the patient was suffering not from hysteria, but from hæmorrhage into the left internal capsule.

She has continued to improve during her short stay in the hospital, but as she was sent in simply for diagnosis and not for treatment we do not think it necessary to

keep her long.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD FRIDAY, APRIL 28TH, 1899.

The President, Mr. Langton, F.R.C.S., in the Chair.

CLINICAL EVENING.

CASE OF ACHONDROPLASIA.

Mr. Turner showed a girl, æt. 10, who looked considerably younger, with no history of syphilis, born of young parents, with two sisters, aged respectively seven and three, in good health, she was only three feet high. The diaphyses of the bones were very short, and had not increased in length part passu with the increase of growth of the epiphyses. The three year old sister was three inches taller than the patient. The clavicle, for instance, was as long as the humerus.

Dr. A. GARROD observed that the case was similar to one which he had shown to the Society last year.

Mr. BARWELL said the lordosis was analogous to that occurring in congenital dislocation (so-called) of the hip, and the result was probably due to an affection of the upper part of the femur, which caused the patient to throw the buttock and tuber ischii backwards.

SOLUTION OF CONTINUITY OF BOTH FEMORA.

Mr. STANLEY BOYD showed a patient, æt. 18, in whom two years ago, after much difficulty in walking, both femora gave way and who had become unable to walk or stand. When admitted to hospital there was a remarkable deformity of both thighs which persisted. Since shown at the last meeting he had applied extension with marked improvement, especially in respect of the left limb. He showed on the screen skiagrams of the lad, which showed the characteristic deformities of rickets, but the shadow of the solution of continuity in the bones was almost as dark as that of the bones themselves.

Mr. W. G. Spencer thought this was an example of one of the general diseases of the skeleton which did not fall into any definite category, and which might be described as intermediate between rickets and osteomalacia.

Mr. Charters Symons referred to a case by Mr. Davies-Colley, reported in the "Transactions" of the Patho-logical Society, Vol. 35, which he said was almost exactly similar. Both femora and both tibiæ were broken, and the child also developed large masses of soft bony tissue in connection with the jaw, ribs, and pelvis. The child died at the age of 15 from paraplegia caused by yielding of the spine and pressure on the cord. It was diagnosed as osteomalacia.

Mr. Barwell suggested that there was something inflammatory about the lesions. There was great pain on the slightest movement of the limbs, and he commented on the fact that the substance uniting the fragments was as dark in the skiagram as the bone itself. He did not consider that the case referred to by Mr. Symons was at all comparable.

REVOLVER SHOT OF THE BRAIN THROUGH THE HARD PALATE. OPERATION.

Mr. A. BARKER showed a man who had fired two shots of a revolver into the mouth and then, despairing, had given himself up to the police. There was free hæmorrhage but no loss of consciousness. Twelve hours after there was no trace of any nerve lesion except a slight drooping of the right eyelid. Eighteen days later he began to vomit frequently, and on the twenty-eighth day it was noted that the left side was growing weak, which by the thirty-second day had become complete. There was marked optic neuritis most pronounced on the right side. Some improvement occurred and in a few weeks he was able to walk about. A skiagram was obtained which showed the position of the two balls. He had several epileptic attacks, and after experiments on brains in the post-mortem room he localised one of the bullets, and trephined over the region, and ultimately succeeded in removing it on the sixty-ninth day. recovering from the operation the patient was completely paralysed, but motion returned first in the leg and then in the arm, feet, and hands. Then it was noticed that his trunk muscles were quite paralysed on one side as shown in screen projections. He had since steadily improved, but as there was optic neuritis Mr. Barker pointed out that the prognosis was doubtful.

The President agreed that surgeons were well advised not to interfere in these cases, seeing that very often the bullet gave rise to no symptoms at all, and he referred to three cases in which no operation had been

found necessary.

Mr. Gould asked whether the author thought it was the removal of the bullet or the relief of tension that had brought about the amelioration in this case.

Mr. BARKER admitted that there was considerable tension, but thought that as the symptoms were on the mend the existence of optic neuritis rendered it likely that the bullet was causing irritation. He asked whether in the cases referred to by the President skiagraphic or other evidence had been forthcoming of the presence of the bullets in the brain.

The President said that in one case a skiagram had been made. His three cases were all in Germans.

Mr. BARKER added that his patient was a Russian.

TUMOUR OF THE UPPER JAW.

Mr. E. W. Roughton showed a man, æt. 39, who two years ago first noticed a swelling on the upper jaw just below the left eye, which had since gradually increased in size. There was a swelling of uniform hardness mainly occupying the left superior maxillary bone, also the nasal bone, and the malar bone. The alveolar process was much thickened, and the arch of the hard palate was much depressed. From the nose it was seen that the floor of the nose was depressed on one side showing that it was a bony growth infiltrating not only the superior maxilla, but also the adjacent bones. He had removed a portion of the growth, which on section prived to consist of delicate trabeculæ of bone with spindle and round cells, and some multinucleated giant cells. It might, he said, be leontiasis or a soft growing sarcoma.

SPONTANEOUS CURE OF RECURRENT CARCINOMA OF THE BREAST.

Mr. A. Pearce Gould showed a woman who had already been shown to the Society in November, 1897. She was single, and æt. 49. In 1888 she received a blow on the left breast which was followed by a lump, which, in 1890 was removed, and on microscopical examination was diagnosed as scirrhus. In 1892 she returned with recurrence in the left axilla which was excised, and in 1894 recurrence had again taken place, and on this occasion there was a lump in the right breast. These were excised in December. In 1895 she returned with another recurrence in the scar and also the lump in the other breast, and enlarged glands in the corresponding axilla. also complained of shortness of breath, and her condition was looked upon as incurable, and she was admitted to the Cancer Ward of the Middlesex Hospital. There were then numerous nodules around the scar and elsewhere, and dulness at the base of the right lung. In March, 1896, she was unable to lie down in bed and there was a large lump in the right thigh bone. Nothing was done, but in June, 1896, she had lost her dyspnæa and the nodules had disappeared. The swelling in the thigh had diminished and was no longer painful. He had shown her in November, 1897, when the scars alone were visible, and he showed her again to prove that the improvement was not ephemeral. Mr. Gould mentioned that the patient had menstruated the last time in January, 1895, and the improvement had been manifested many months later, viz., between March and June, 1896. He commented on the fact that no credit could be given to any treatment, for she had had none, and the improvement had taken place in the cancer wards of the hospital devoted to cancerous patients for the last fifty years.

Mr. CLEMENT LUCAS asked whether Mr. Gould himself

Mr. CLEMENT LUCAS asked whether Mr. Gould himself had made any microscopical examination of the growths. He mentioned that he had tried oöphorectomy in one case, but the growth in the breast had doubled in size within the six weeks following the operation, and he had subsequently removed it.

Mr. Gould said he had not made any sections while the patient was under his care, and he had no explanation to suggest of the subsidence of the growths.

UNILATERAL HYPERTROPHY OF THE ACCESSORY MUSCLES OF RESPIRATION.

Dr. A. Morison showed a woman, æt. 35, with unilateral hypertrophy of the accessory muscles of respiration viz. the trapezius, sterno cleido-mastoid, and scaleni.

A NEW SPLINT FOR FRACTURED CLAVICLE.

Dr. Mouat-Biggs showed a man wearing his splint for fractured clavicle, which he had had in use for this injury for the last fifteen years. He claimed for it that it afforded complete immobility of the fractured bone, with much less discomfort than the usual appliance.

EXCISION OF THE POSTERIOR HALF OF THE TONGUE AND EPIGLOTTIS.

Mr. Stanley Boyd showed a patient (with specimen) who, when seen, presented an epitheliomatous rumour, involving the posterior half of the tongue and the epiglottis. The growth reached nearly back to the spine. He removed it by opening the pharynx and removing a portion of the hyoid bone, the tumour reaching down to the thyroid cartilage. The removal of the tumour left a cavity which he closed by a purse-string suture, and the patient was able to swallow on the fifteenth day. Some recurrence had taken place low down in the neck where the glands were not readily accessible, and this he had removed. The patient had since gained in weight, and the tongue looked fairly normal, but there was some narrowing of the pharynx.

INJURY TO THE ROOTS OF THE BRACHIAL FLEXUS IN AN INFANT.

Dr. Batty-Shaw showed an infant, 13 months of age, in whom, consequent on violence exerted at birth on the left arm, impairment of motion had resulted in the corresponding limb. Sensation was not affected.

PULSUS PARADOXUS.

Dr. Norman Dalton showed a man, age 48, with no history of rheumatic fever, syphilis or alcohol, who had râles and coarse friction over the lower two-thirds of the left lung, but no dulness. There was marked retraction of the apex beat, which extended from the ensiform cartilage to two inches below the nipple. There was also typical pulsus paradoxus, but no other signs of adherent pericarcium, or of chronic mediestinal cellulitis. The heart sounds were normal, and the heart action strong. As no tuberculous bacilli could be found, he suggested that there was probably chronic interstitial pneumonia, with pleuritic adhesions in the lower part of the left lung, with probably much fibrous tissue between the heart muscle and the chest wall and diaphragm, and a certain amount of pericardial adhesion, though not enough to embarrass the heart.

A CASE OF AORTIC DISEASE WITH MUSICAL BRUIT REMEDIED BY BATHS AND EXERCISE.

Dr. Bezlet Thorne skowed a man, æt. 45, without marked hypertrophy of the heart and no increase of cardiac impulse. After an effort he had become breathless, and had developed a musical bruit and he had become

incapacitated for work. Under treatment by baths and graduated exercise be had gained in health, though the exaggerated cardiac duiness remained unaltered, and he was about to resume work as a timekeeper.

EXCISION OF A MENINGOCELE (WITH SKIAGRAM).

Mr. W. G. Spencer showed an infant who, when seven months old, was operated upon for spinal bifids, and he showed a skiagram of the cavity. Previous to the operation the child had never been seen to use its lower limbs at all, but since, it kicked about like a normal child. He had opened the sac and dissected out the cauda equina, &c, bringing together the walls of the sac by a double row of sutures, and keeping the child in such a position that the wound was the highest part. No untoward symptoms had followed and no cerebro-spinal fluid had escaped through the wound.

OSSIFICATION OF THE TENDO-ACHILLIS.

Mr. WILMOTT EVANS showed an elderly man who presented a hard tumour in the left tendo-Achillis, which in skiagram appeared to be calcified if not ossified. There was a history of two injuries twelve and eight years ago, but the condition was not noticed until twelve months ago.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, MARCH 17th, 1899.

Dr. W. J. SMYLY, in the Chair.

Drs. Purefor, Glenn, and A. Srith inaugurated a discussion on the action of the General Council of the Academy in refusing the recommendation of the Obstetrical Section to print and circulate among the members the reports of the Rotunda Hospital, and after some further discussion it was resolved "That the Council be asked to reconsider their decision, and that in future hospital reports of sufficient interest be printed and circulated among the Fellows of the Academy."

SPECIMENS OF MYOMA UTERI.

Dr. Alfred Smith exhibited three myomatous uteri removed by retro-peritoneal hysterectomy. 1. The first specimen was a large soft myoma which had been removed five days previously. The patient had given birth to two children, and after the birth of the younger came down to the size of a three months' uterus. The tumour, which was considerably @dematous, and blocked up the pelvis completely, extended well into the broad ligament. 2. The second specimen was a small fibroid, which he removed on account of the constant trouble which it gave to the patient during micturition. On cutting through the pedicle there was no hemorrhage, and he found that there was only one uterine artery developed to any extent, and that was on the left side. The absence of an uterine artery on the right side was the chief point of interest in this specimen. 3. The third specimen which he had removed a fortnight ago was large, and appeared to him before operation as sub-peritoneal and pedunculated. On operating, however, he found a second pedicle intimately adherent to the promontory of the sacrum, and this gave him considerable trouble until he found out the condition. He then attempted to perform a myomectomy. He put a clamp round the cervix in the ordinary way in order to suppress hæmorrhage from it, and then proceeded to amputate the large tumour which he exhibited. On loosening the ligature, however, there was hæmorrhage everywhere. He tied several arteries, but notwithstanding this he could not arrest the hæmorrhage, so that he was obliged to perform hysterectomy. The patient did remarkably well.

Dr. Purerov said that Dr. Smith's failure to find the uterine artery on one side was another illustration of the variations in size which one often observed in different cases in the uterine vessels. It was very difficult to forecast what the bebaviour of a fibroid would be. There were some harder than others, and the rate of growth

in these cases was comparatively slow. The difficulty Dr. Smith had in controlling the hæmorrhage in the case of myomectomy showed that one ought to be prepared for an emergency, even in the case of a tumour with a small pedicle. He suggested that tying the ovarian arteries might have had some effect in checking the hæmorrhage in this case.

Dr. SMYLY suggested that the small tumour might

have been removed per vaginam.

Dr. Smith, replying, said there seemed to be a growing opinion that operation should be the treatment in the case of fibromata. He looked upon these cases as strong arguments in favour of operative treatment. The uncertainty of the prognosis was another point in favour of operation. As regards the shock of removal of the uterus by the retro-peritoneal method, his experience was that patients suffered more pain and distress after removal of the tubes and ovaries only, than when they removed the tumour and the uterus down to the level of the cervix. With reference to Dr. Smyly's suggestion, the reason he removed the tumour from above was on account of the long pedicle attached to it making this

The Section then adjourned.

LIVERPOOL MEDICAL SOCIETY. MEETING HELD THURSDAY, APRIL 13th, 1899.

DR. MACFIE CAMPBELL, President, in the Chair.

DR. FRANK H. BARENDT showed a patient, male, æt. 13, with prurigo erox. The history, general appearance, and the distribution of the eruption agreed with Hebra's account of the disease in every particular. The "eczematisation" of the skin due to incessant scratching with prurigo efflorescences glimmering through, and in the vicinity of this secondry eruption, was most marked on the shins and forearms. The thighs, buttocks, and arms, with the exception of the internal aspects displayed red ridges and configured area of thickened integument decked with fine asbestos-like powder. The "prurigo buboes" were well marked in the inguinal and axillary regions, and the integument when free from rash, was harsh to the touch. The expression of the patient was miserable, he rarely passed a night without scratching, and owing to the disease which began in infancy, had been unable to attend school or associate with other children. The father had recently died of phthisis, and the patient constantly suffered from pulmonary trouble. The family history shed no light on this incurable affection. Treatment was only palliative, and at present he was using B. naphthol (gr. v. benzoated lard 3) ointment, a dusting powder of equal parts of talc, starch, and oxide of zinc, and olive oil to be used in the place of soap and water.

Mr. Rushton Parker showed a man, æt. 48, upon whom he had performed pylorectomy on January 16th, 1899. Stomach troubles had existed five or six years, and recently pain after food, and vomiting had reduced him to emaciation. No tumour was to be felt, but a diagnosis of carcinoma was assumed provisionally. At the operation a hard tumour was found in the posterior wall near the pylorus. The mucous membrane was thickened, but not ulcerated, and although the growth was doubtful, and not strongly suggestive of carcinoma, excision seemed the only practical way of dealing with it, especially as the local circumstances were favourable; accessibility, and absence of lymph or glandular infection. The duodenum was attached to the stomach by continuous silk stitches, one set for the mucous membrane and the other for the peritoneum, and the remaining gap in the stomach was closed by attaching its sides in the same position. The patient made a good recovery, and in a few weeks' time was able to eat ordinary food. The growth showed no evidence of carcinoma, but was evidently of syphilitic origin, as evinced by small gummata and arterities and cellular incomplete the conditions. infiltration. On April 13th he was in good health and free from stomach affection, but had not yet returned to his heavy work of boiler-making.

Mr. RUSHTON PARKER also showed a young man, æt.

21, upon whom he had performed pyloroplasty on January 23rd, 1899. There had been a history of dyspepsia for five years and a condition of dilated stomach, but no symptom suggesting gastric ulcer. At the operation the pylorus was narrowed to } in. diameter outside. This was laid open, and a small circular ulcer found just inside the stomach. Pyloroplasty was per-formed over a Mayo Robson's decalcified bone bobbin, and the diameter of the pylorus increased to 1½ inches outside; he made a simple, uneventful recovery. For three weeks the patient was fed on milk as in the treatment of gastric ulcer; after that he ate fish, and in a month or five weeks' time ordinary meat diet; and later resumed his occupation as carter on a farm. On April 13th he was in good health, plump and well, but still a little weak, he said, on his legs.

Dr. Grossman described a method which he has employed for localising foreign bodies in the eye by means of X-rays. In contradistinction to Mr. N. Davidson's stereoscopic method (British Medical Journal, Jan 1st. 1898), he utilises the movements of the eye for obtaining the parallax of the shadow of the foreign body, the Crookes' tube, the patient's head, and the sensitive plate retaining the same position in two successive exposures. It may be necessary, under certain circumstances, to make two pairs of exposures in order to obtain both the vertical and horizontal parallax. The author claims for this method that it is simpler than the stereoscopic method, and that a path can be chosen for the X-rays

which offers the least amount of bony opacity.

Mr. R. W. Murray exhibited a child upon whom he had operated for general suppurative peritonitis associated with a gangrenous appendix. The patient, a boy of nine years, was first seen by Mr. Murray during last September. He had been seriously ill for five days with abdominal pain, constipation and continuous vomiting. The abdomen was much distended, tender, and tympanitic. On opening the abdomen the intestines were found bathed in pus, and bubbles of gas came from the right iliac fossa. The median incision was enlarged, the intestines turned out of the abdominal cavity, and the appendix, which was seen to be gangre-nous and perforated, excised. The abdomen was then well washed with warm boracic lotion, the distended intestines, after being cleansed, were with some difficulty returned, and the wound closed, except the lower part, where a drain was inserted leading to the stump of the appendix. After an anxious convalescence the child ultimately made a good recovery.

Drs. and Messrs. Humphreys, Parker, N. T. Thomas,

Raw, Barr, Grünbaum, and E. T. Davies took part in the

discussion.

Mr. MURRAY replied.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 29th, 1899.

Following Dr. Kocher's paper on epilepsy, at the Surgical Congress, was one by von Bergmann, on

PORENCEPHALY,

at which the patient was shown, and which the speaker said bore out Kocher's theory as to epilepsy. There was a cyst formation in the head which often led to epilepsy. This was the traumatic form of the disease, but not all cases were of that nature. The clinical features of the disease were quite typical, there were localised paralyses with contractions, and arrest of growth in the paralysed extremities in childhood, there were epileptiform attacks; the patients were imbecile, or at least their intelligence was defective. The case shown was one of traumatic porencephaly, from a fracture of the skull caused by pressure of the forceps at birth. There was a cyst in the skull, but apparently no meningocele. During the epileptic attacks, and when the head was

sharply flexed, however, the open space became tense, and the skin thrust forward. According to Köning, when such defects were covered with bone, a cure was effected. This had been attempted after extirpation of the cyst, and as the margins of the defect was very thin, like the skull bone of a child, a bone flap had been taken from the tabula vitreca and pushed over the defective spot. Thecovering-in was not successful, however, until after several operations, as the space had a length of 14 c.m. and a maximum width of 8 c.m. The first operation was at the beginning of April, 1898, and the last on July 11th. A small part still remained uncovered, the requirements of Kocher as regarded "ventilation" were therefore fulfilled. The epilepsy had ceased. The child (shown) displayed shortening of the left upper and lower extremities, left-sided club foot, and spastic position of the As the cyst communicated with a lateral ventricle drainage had been kept up for a long time. The anatomical features of this porencephaly were constant. The speaker showed a preparation from a child of 7 who had died of collapse after operation, but had not suffered either from fits or paralysis, though there was a very large tumour. When operation was to be undertaken, he urged that Kocher's procedure should be followed, although it could not be diagnosed with certainty whether intracranial pressure was always increased or not The most important indication was always causal, and the treatment should always be carried out before an epileptic condition of the brain had become established.

GUN SHOT INJURY OF THE BRAIN.

Mr. Arthur Barker, of London, read a case of "Gunshot Wound of the Brain, Removal of the Bullet by Trepanation with Recovery," which was followed by Krönlein, of Zurich, on "Gunshot Injury of the Brain.' The interest of the latter case lay in the destruction that had been wrought, the suicide having taken his life with a Swiss ordnance rifle of 7.5 c.m. calibre. There were gaping wounds in the skull, the bone being much shattered, but with the dura still connected, the interior of the skull was perfectly empty, but the brain blown completely out. This was found almost uninjured, lying on the ground about two feet away from the body. almost as if it had been taken out by a skilled hand. No trace of the passage of a projectile could be found in the brain. There was only slight tearing at the root of the brain running along the base. cerebellum was torn away from the cerebrum, and lay five foot farther away. How had the concentra-There could be only a hypotion taken place? thesis regarding it, viz., that the blowing out of the brain was the result of hydraulic pressure. In another case of shooting with the same arm, when the shot took effect on the margin of the left upper alveolus, the left eye was torn out. The shot had an external opening opposite in the upper part of the temple. That the shot passed through the brain, therefore, there could not be the slightest doubt, but the patient did not lose consciousness even for a moment, and he was now in a condition of undisturbed convalescence.

Hr. Lauenstein, Hamburg, could confirm Kocher's statements as to the useful effect of removing brain pressure in epilepsy. A man, æt. 20, had suffered for seven or eight years from frequent attacks (latterly almost daily) of epilepsy, starting from the left motor cortical centre. The patient was then blind, and the lef

arm paralysed. Operation was performed, but no tumour or cyst was found. The dura was now replaced and the periosteum lightly laid over it. After the operation the fits ceased and also the blindness, and the hemiplegia was much improved. The defect, as Kocher had recommended, was not completely covered in with bone, a space being left for relief of intracranial pressure.

Hr. v. Bergmann showed a patient who, in 1895, was shot in the right temple. He remained unconscious for fourteen days, and then had left-sided paralysis; two months later, epilepsy came on. The bullet could not be found on trepanning. In 1897, symptoms of abscess came on, and the pus was evacuated. The defect in the skull was covered with periosteum; but two fistulæ still remained. The epilepsy had entirely ceased. The bullet lay in the antrum of Highmore, and not in the brain.

Hr. v. Bech, Carlsruhe, reported eight cases of traumatic epilepsy, partly treated by himself, and partly by Czerny, in the Heidelberg Klinik. Three, in which no care was taken to cover the defect with bone, had completely recovered. The others were cases that had suffered from epilepsy from childhood from osteophytic formations within the skull. In these a bony covering was attempted. So long as this covering remained a loose one, the epilepsy remained well, but it returned as soon as the covering grew firm. In one case the lateral ventricle was drained, and recovery took place. These cases were in favour of the correctness of the view taken by Kocher.

Austria.

FROM OUR OWN CORRESPONDENT.]

VIENNA, April 29th, 1899.

UTERUS MYOMATOSUS GRAVIDUS.

Wertheim exhibited a preparation at the "Gesell-schaft der Aerzte," which he had removed from a patient, at. 32, in her first confinement, by the Caesarian section. The myoma was situated immediately behind the neck of the uterus, occluding the channel so completely that embryotomy was impossible. The fectus weighed 4,680 grammes or 10.296 lbs., and 56 centimetres or 22.047 inches in length. On opening the uterus, a penetrating odour was intense; the decidua was purulent, which excluded, in Wertheim's opinion, any conservative operation, and therefore extirpated the entire organ, which was followed with perfect recovery.

The Kaiser operation, he said, was not uncommon in "uterus myomatosus," but the mortality was so high that little or no favour had been extended to it, as thirty-one deaths out of thirty-eight cases operated on with conservative endeavours was not at all encouraging,

By Porro's method the conditions are better, three deaths occurring in fifteen. The Kaiser operation with total extirpations is by far the most successful.

Wertheim is convinced that this case would have decidedly died of septicæmia, had he attempted conservative principles.

TUBERCULOSIS OF THE PENIS.

Ehrmann exhibited two men with tuberculous ulcers on the external surface of the urinary canal. In December of last year the first case commenced with laryngeal tuberculosis in the lower commissuire, which soon healed with the application of iodoform vasogen. On the 13th

of the present month the patient returned with three ulcers immediately in front of the cicatrices of the former ulcers. In the secretion of the penal ulcer tuberc lous bacilli were found, but nothing in the urine. The bladder and prostate were in a normally healthy condition.

The second case was one suffering from tuberculous thickening of seminal duct, bladder, and prostate. In the urine and secretions the tuberculous bacilli were found in large numbers. Ehrmann related the history of 'a third case with "Moulaye" of the glans penis which had healed up, but the examination of the sores, urine, prostate, and bladder revealed the tuberculous bacilli which led to a diagnosis of the kidneys being the primary source of the disease. He thought the infection from these sores must be very varied. The primary cause in these genital affections could be traced to the kidneys and infected as the sputa; or it might arise in the blood and thence be transmitted to every organ of the body. It does not require much force of conception to perceive that ulcers of the glans penis may be a source of general auto-infection. The careful treatment of all these sores, in his opinion, should demand constant attention. He instanced a case where twenty inunctions had a very beneficial effect.

THE PROGRESS OF RONTGEN PHOTOGRAPHY.

Kaiser referred to Siemen's and Halske's improved Hg. interrupter as a great advance in Roatgen photography, as it removed the sound and the flickering of the light. The mode of application was to fill a cylindrical with dilute H₂ SO₄, into which are fastened a plate of lead and two of platinum. The current decomposes the H₂ SO₄, from which gas bubbles are evolved that stick to the electrode and immediately produces an interruption. The bubbles soon disappear and the current commences anew. The other improvements were in the plates, which are now lighter, cheaper, and more sensitive than ever they were.

He next recounted the various objects that disappeared or remained permanent on the photograph. In those of the head, the hair quite disappeared, while the bones remained quite distinct on the shadow. It was very rarely that the ethmoid bone or sulci arteriosi could be observed; on the other hand metallic substances, fractures, pus, bony splinters, tumours in the nasal passage and maxilla can be noted. Tumours in the brain cannot be detected by means of the Röntgen rays. In the neck the spinal canal, pharyngeal cavity, root of tongue, traches, and even the gullet can be defined. In the thorax, clavical, scapula, ribs, and head of the humerus can be traced. The intercostal spaces can be judged by the respiratory movement. The heart can be clearly defined by lighting both behind and before when its movements can be readily followed, but it is impossible to discern any morbid changes like calcification in the heart or vessels. The curve of the aorta can only be seen in children, hence any changes like aneurysms, &c. can be easily detected. The lungs appear on the photo clear, though tuberculous infiltration produces a cloudy condition. Gangrene or tuniours are sharply defined. exudations of the pleura are easily recognised. In the abdomen, duodenum, gall-bladder, stomach, and its contents can be observed, but the pancreas cannot be

The Operating Theatres.

GUY'S HOSPITAL.

FOR COMPLETE EXCISION OF LARGE Volvulus of Sigmoid,—Mr. Arbuthnot Lane operated on a case of intestinal obstruction in a middle-aged woman who had been admitted under Dr. Frederick Taylor. Her abdomen was enormously distended; the bulk of the swelling seemed to be due to the presence of a large resonant mass in its interior projecting beyond the adjacent coils of intestine. The patient gave an indefinite history of attacks of previous obstruction which had been both acute and chronic. Mr. Lane made an incision along the length of the linea alba through which there at once leaped out a hugely distended coil of bowel; this measured 1 yd. in length and 18 ins. circumference; the wall of the bowel was exceedingly thick, and its mesentery opaque and scarred. Further examination showed that the condition was one of volvulus of the sigmoid. He adopted the method of excision which he had urged at a meeting of the Clinical Society of London on April 26th, 1895, and resected the whole lump, using the largest size of Murphy's button for the purpose of joining the divided ends, controlling the proximal and distinct portions of the bowel during the process by his own clamps which are now used pretty universally. It was the largest volvulus that Dr. Taylor or Mr. Lane had ever seen. Mr. Lane said that it seemed to him that this method of excision was the only scientific plan, as he had before pointed out at the Clinical Society, in the discussion of the paper on "Acute Intestinal Obstruction," by Dr. F. L. Benham and Mr. Silcock. It was quite clear, he pointed out, from the condition seen in the case he had just operated upon that any other recognised form of treatment would not have brought about the complete restoration of function which he hoped might result in this patient. The reasons in favour of excision were, he said: (1) that recurrence is impossible. (2) That a loop which is often acutely inflamed and extensively ulcerated, and the source of immediate danger from perforation, gangrene, septic absorption, &c., is at once removed. (3) That no drainage is necessary, and no fistulous opening can remain. (4) That it is a procedure to which no reasonable objection can be offered. Button was passed on 31st day.

The patient made an uninterrupted recovery.

OPERATION FOR INTESTINAL OBSTRUCTION DUE TO INTUSSUSCEPTION.—The same surgeon operated on a child, six months old, who had been admitted under Dr. Fred. Taylor. He opened the abdomen in the middle line, and found an intussusception in the iliac fossa, which had been diagnosed before the operation but whose presence could not be detected on account of the considerable distension of the abdomen. The intussusception was reduced by traction and firm pressure.

Mr. Lane pointed out at the operation that the free exposure of the whole interior of the abdomen by means of a long median incision, in this, as in other conditions of intestinal obstruction, facilitates enormously the observation of the cause of the obstruction and its treatment, and reduces to a minimum the duration of the operation and the extent of the shock to which the patient is exposed. The advantage of a long incision he thought was most conspicuous in cases in which the seat and cause of the obstruction were in doubt.

The progress and recovery of the child was monotonously satisfactory.

WEDNESDAY, MAY 3, 1899.

AN ANTI-VIVISECTION GALA.

At the close of the twentieth century we find ourselves living in an age of demonstrations, organised by every grade of society for the purpose of airing every kind of belief. In some instances the motives are worthy of a place in the great onward march of civilisation, in others they are simply irrational outbreaks that serve to register the stages of the social and scientific progress. Among the latter futilities may be reckoned last week's meeting of the London Anti-Vivisection Society. As the speakers were in many respects representative of the particular views to which they owe their communion, it may be well to examine the logical value of this official gospel. It may be premised that in all the history of modern societies founded for protesting against commonly accepted views and practices, none have been more noisy, more assertive, more caluminous and less supported by facts and reasons than the sect of the anti-vivi-Like their first cousins, the antivaccinationists, they boldly run counter to the practically united voice of the medical profession. In neither case are their peculiar tenets supported by men of scientific standing in the medical profession, although each has contrived to gain a single adherent whose name is known in the medical world. The antivivisectionists have naturally made the most of their capture, and have advertised for weeks past in the public journals that an "eminent surgeon" would address their meeting. The propositions advanced by this new pillar of support, a pervert from his former views, were briefly that experimentation on living animals is crude in conception, unscientific in its nature, and incapable of being applied to the nevertheless convinced that it was "a wicked and an

benefit of humanity, and that the inspectors of vivisection should be appointed from the legal rather than from the medical profession. The first three assertions may be taken together. Man is the issue of a stock common to the rest of animal life, and has been placed by the process of evolution at the head of the mammals, at least, that is the view of every modern biologist of note with whose writings we are acquainted. In a great number of instances, if not in the majority, the tissues of the lower animals react to injury and disease in a manner analogous to those of mankind. The moral right has been assumed by the higher species to make use of the lower for food, for forced labour, for sport, and for other purposes. Can it be seriously maintained that there is less justification in testing some pathological problem, say, on a guinea-pig, than in killing a heron by means of a trained hawk, for purposes of sportnothing more and nothing less, wanton in its conception, brutal in its tendencies, and useless in its results. Yet the ancient pastime of hawking is undergoing a flourishing revival in our midst at the very moment when the anti-vivisectionists are filling the air of St. James's Hall with their resounding accusations. Let us take an example of modern "vivisection," using the word in its strictly technical sense. It is desired to test the action of a specific pathogenic micro-organism, say, that of tuberculosis, and for that purpose cultures can be injected, among others, into fowls, guinea-pigs, rabbits, cattle, and horses. In this way much invaluable information has been gained as to the life-history of the tubercle bacillus outside the human body, and especially in its relation to the communication of the malady from the lower animals. It must be borne in mind, moreover, that the existence of the specific bacillus was discovered and proved mainly by experimental evidence obtained from "vivisection." We fail to see anything crude or unscientific in this chain of investigation, which is exactly reproduced in a hundred and one other directions. Even if the results upon a particular animal, say, a goat, prove negative, they simply set the investigator at work to find the reason of that immunity, and in that way the brilliant chapter of serum-therapy has been placed in the hands of the modern medical man. Such results will require more to upset them than loose assertions addressed to the emotions of a scientifically untrained audience. As to appointing the vivisection inspectors from the legal profession, we might as well entrust the latter with the control of the vaccination, lunacy, and anatomy acts, and with the control of the General Medical Council itself. That the "eminent surgeon" carried his audience with him goes without saying In the absence of complete justification of his now position the greater the eminence the more disastrous is likely to be the fall. The value of their support, however, may be gauged from the utterances of the worthy Bishop of Nottingham, who although he had no "practical knowledge" of vivisection was

evil thing." Then the meeting proceeded by easy stages to condemn the whole medical profession for making experiments upon patients in hospitals. The ground upon which that gratuitous assumption rests has been thus cut away by the editor of a London newspaper. "The fundamental fallacy," he says, "on which the agitation of the London Anti-Vivisection Society is based would appear, soberly, to be this: It conceives that vivisection is undertaken in pure wantonness. for the fun of the thing as it were, and that the lust of sport grows on the practitioner till he prefers a human being to an animal subject." It is to be regretted that any member of the medical profession should appear to sanction by his unprotesting presence a view that Mr. Eden Phillpotts has eloquently described as "a deliberate insult hurled at every great London hospital, where science and humanity go daily hand in hand for the welfare of the race."

PREGNANCY AND THE THYROID GLAND.

DURING pregnancy, and even to a slight extent during menstruation, the thyroid gland undergoes more or less pronounced enlargement. This becomes noticeable towards the fifth month of gestation, and continues until the end of the puerperal period, and it is a physiological fact to which, perhaps, sufficient attention has not been paid for it may possibly help to explain a whole train of nervous symptoms of which, so far, no explanation has been attempted. The first question that suggests itself is whether the enlargement is due to simple hyperæmia or whether it is a genuine hypertrophy. To determine this point. Dr. Lange, of Berlin, administered thyroid preparations to several pregnant women under his care, with the result that under this treatment the gland diminished in size, the engorgement reappearing as soon as the treatment was suspended. He infers from this fact that the enlargement is really of the nature of hyperplasia, such hypertrophy being a strictly physiological pro-The only possible explanation of this phenomenon is that there exists in the blood of pregnant women a substance, or substances, peculiar to this state, which is or are capable of acting directly upon the thyroid gland. It must, however, be borne in mind that all pregnant women do not display this tendency to enlargement of the thyroid. Thus, of 133 women observed during the last three months of pregnancy, 25 did not exhibit any tendency to glandular enlargement, but of these 25 no less than 18 were suffering from the albuminuria of pregnancy. As, on the other hand, women suffering from chronic nephritis exhibit this gestation goitre in the usual way, Dr. Lange concludes that the thyroid hypertrophy is more likely to be absent in women who fall victims to one or other of the renal affections associated with the pregnant state. It is obvious that the non-existence of "gestation goître" cannot be due merely to the existence of the albuminuria of pregnancy, seeing that the latter makes its appearance, as a rule, much later than the hypertrophy of the gland, and, moreover, it has been shown that that of forty-five tetanised guinea-pigs treated by

Bright's disease by no means interferes with the development of this ephemeral variety of goître. Comparative experiments on pregnant cats seem to show that pregnant animals require a larger volume of thyroid gland for the maintenance of health than non-pregnant animals, and when more than fourfifths of the gland are removed the animal develops tetany, which subsides under the administration of thyroid extract. Moreover, in a cat possessed of sufficient thyroid gland to maintain health under ordinary circumstances, the supervention of pregnancy is soon followed by symptoms of more or less pronounced renal disease. Clinical experience, as far as it goes, seems to confirm these experimental data, for Dr. Lange has had under observation two women who, during their first pregnancies, had albuminuria and no goître, whereas in subsequent pregnancies they presented this hypertrophy of the thyroid gland and no albuminuria. These facts would seem to warrant the inference that there is a close relationship between the activity of the thyroid gland and that of the kidneys, and it is conceivable that another field of usefulness may be opened out for this protean medication, not only in obstetrics, but also in gynæcology, for it is quite possible, though no clinical demonstration thereof is as yet available, that some forms of dysmenorrhœa may be dependent upon deficient activity of the thyroid gland, the importance of which in the animal economy has so recently been demonstrated.

THE NEW METHOD OF TREATING TETANUS.

THE successful case at the West London Hospital of the treatment of tetanus by intra-cerebral injections of antitoxin, recorded under "The Operating Theatres "last week, is, we believe, only the second instance published in this country in which the new method has been tried. Of course it is impossible to claim for this method that it has solved the difficulty under which, so far, surgeons have laboured in their treatment of tetanus; nevertheless, it is impossible to dispute that it appears to be founded upon a substantial, scientific basis, and that its trial, up to the present at least, while not being uniformly successful, still gives promise of affording more satisfactory results in the future. We may here recall that Roux and Borrel, from experiments carried out at the Pasteur Institute in Paris, determined that the toxin of tetanus becomes stored up in the nerve-cells, while the antitoxin injected into the blood in the treatment of the disease does not reach the cells in which the poison is contained. The authors assumed, therefore, that this was the explanation of the frequent failure of the intravenous and subcutaneous injections of antitoxin which had hitherto taken place. Hence the idea occurred to them of bringing the poisonladen nerve-cells into direct contact with the antitoxin by means of intra-cerebral injections. proof of this assumption their experiments showed

these injections, no fewer than thirty-five recovered, while of seventeen others treated by simple subcutaneous injections only two survived, and of seventeen not treated in any way, a fatal result ensued in every instance. The principle, however, of the treatment does not exclude the continuous use of the subcutaneous injections; indeed, it is deemed to be highly essential that these should not be in any way interrupted, the idea being that the circulation of the fresh supplies of antitoxin in the blood will neutralise the poison which is secreted at the seat of injury before the opportunity is afforded it of reaching the nerve-cells. A detail of some importance, also, seems to be to excise the tissues in the neighbourhood of the wound from which the tetanic infection has taken place. The soundness of this practice cannot be disputed. As long as the infected tissues are allowed to remain, so long, it is reasonable to assume, will fresh secretions of the toxin continue to gain entrance to the blood. Those who are interested in this subject will find a résumé of the recorded cases, up-to-date, published in the April number of the Annals of Surgery. So far as they go, the cases clearly point to the value of the new treatment, but time only can show, with increased experience of its practice, whether intra-cerebral injections of tetanus antitoxin will solve the problem of the treatment of this fatal and terrible disease.

Aotes on Current Topics.

Dockrell v. Dougall.

WE regret to learn that the plaintiff in this important legal case has failed on appeal. Our readers will remember that the action was originally brought by Dr. Morgan Dockrell for an injunction to prohibit one Dougall, the manufacturer of a certain nostrum, from using his (the plaintiff's) name in his advertisements. The jury, a common jury, from several points of view, held that the statements contained in the advertisement complained of were not libellous, and so the action failed. The Judges of Appeal held that as the finding of the jury was final in respect of the alleged libel, the verdict could not be disturbed, but Lord Justice Vaughan Williams took advantage of the occasion to observe that the verdict must not be held to mean that the advertiser of a quack medicine had a right to use the name of an eminent (or any other?) physician without his authority. Such a course, his lordship added, would constitute an actionable wrong which a British jury would unquestionably regard as justifying exemplary damages. cumstances in this particular case which, in all probability, led the jury to their conclusion, were peculiar, in that the plaintiff admitted having prescribed and taken the nostrum of which apparently he approved, though he had given no authority for his name to be used in connection therewith. The moral is that medical men may look to the law to protect them against the unauthorised and damaging | verdict of posterity in request of claims to this sort

use of their names, on condition that they are careful to keep altogether aloof and avoid affording any colourable pretext for the act. Dr. Dockrell's discomfiture ought to prove a useful object lesson to the profession generally, and now that he has effectually cleared himself of any suspicion of connivance with or approval of the defendant nostrum-vendor, he himself will concede that it is imprudent to have any sort of dealings with unscrupulous persons of that ilk. "The front door, and the sooner the better!"

Public Analysts and Somerset House.

WE venture to submit that it is high time that some definite understanding should be arrived at between the Society of Public Analysts and the analytical authorities at Somerset House by which the constantly recurring wrangles in the courts of law between them respecting the standard of purity of disputed articles may be avoided. It is nothing less than a scandal that two or three public analysts should appear in the witness box to swear to the ccuracy of a certain analysis, and that, when samples of the impugned article are sent forward to the Government tribunal, the analysts swear something like the opposite. This regrettable difference of opinion is all the worse when the defendant's counsel states in court, as was recently done, that the sample must be sent to Somerset House because there is a ring among the public analysts to prevent of them from differing from the finding of another. Now we do not believe a word of that statement, and we know that the contest of analytic opinion is only apparent, it being considered by Somerset House, as in the case to which we now refer, that the obvious deficiency of the sample which the Public Analyst regarded as indisputably the result of sophistication, might possibly have arisen from negligent washing, without any fraudulent intent. It is our suggestion that, as the Somerset House people have always inclined towards the accused, and the analysts have, perhaps, been disposed to be over-strict in their standards of purity, it would be much better for the latter to try to raise the Somerset House standard by conference and persuasion, and, failing that, to sacrifice a little of their scientific virtue by accepting the official standard. Certainly, as the result of many trials of strength between the rival opinions, the public is rapidly coming to the conclusion that analysts' judgment is as little to be depended on as doctors' verdicts.

Medical Biographies.

It is always interesting to know how the world wagged in medical circles in times past, but our knowledge of medical celebrities of bygone centuries is mostly of a fragmentary nature, gathered from many sources, and laboriously patched together. Thanks to the researches of a few labourers in this vineyard, we are enabled to follow up the career of the medical worthies of the last hundred years or so, but though it is given to no man to forecast the

of ephemeral immortality, there is no reason why measures should not be taken to hand down duly authenticated memoirs of celebrities of more recent We hear with pleasure that Mr. J. Y. date. W. MacAlister, the librarian of the Medical and Chirurgical Society, is engaged upon a collective biography of the principal medical The biographer men of the nineteenth century. may not have much that is new to say with respect to those belonging to the first half of the present century, but Mr. MacAlister's almost unique acquaintance with eminent members of the profession of this end of the century promises to make the work one of exceptional interest. The dismal practice which prevails at certain societies of reading obituary notices of deceased fellows at stated intervals provides an unlimited supply of ready-made notices, not unfrequently rather bluntly put, which will facilitate the task of compilation. On the whole we would advise the author to act on Butler's wise maxim to "call no man happy not until he's dead," leaving it to his sorrowing relatives or, failing them, to his executors, to subscribe to the work when it appears.

The Dalrymple Home for Inebriates.

THE last annual report of the Dalrymple Home for Inebriates at Rickmansworth is a most encouraging one in many ways. In the first place during the past year the number of patients who presented themselves for treatment established a record, and the financial position of the home was correspondingly good. The committee of the institution also express their satisfaction with the Inebriates Act of 1898, a point which it is of interest to emphasise, inasmuch as the favourable testimony of such experts in the treatment of inebriety must be regarded as a substantial proof that the Act in question was well conceived and has met a decided want. The new Act, as the committee assert, strikes the first blow at personal liberty when abused by drink, and so far is limited to those who, by their conduct as criminals or the subjects of petty offences, are the greatest nuisance to society. Hence it does not go far enough, since it has little application to those who keep themselves out of the clutches of the criminal The committee, however, trust, when sufficient time has elapsed to satisfy the State as to the value of this extended legislation, that a further step will be taken so as to include, with proper safeguards, compulsory clauses applicable to the many thousands of cases which are not at present touched by the provisions of existing legislation. The report alludes to the deep loss which the Home has sustained by the retirement of Dr. Norman Kerr, who, from continued ill-health, has been compelled to sever his active connection with the Institution and its work. The resignation, also, of Dr. Branthwaithe, who for the past fifteen years has filled the post of resident medical superintendent, is announced. Dr. Branthwaite has been appointed an Inspector at the Home Office under the Inebriates Act.

A Sanitary Tangle.

A curious case, involving a judgment of an extraordinary nature, was settled last week in a London Police Court. The proprietors of the Carlton Hotel, a magnificent structure just erected in the West End at a cost of £500,000, were summoned for having no less than nine soil-pipes inside the building, instead of outside, as directed by the London County Council bye-law. For the defence it was urged that to alter the drains would mean to pull the building half down. The magistrate thereupon adopted what we believe to be the unparalleled course of imposing a fine of £2 and ten guineas costs. It follows that the drains are to be allowed henceforth to remain in their present position, that is to say, one that is clearly condemned by the Council bye-law. If there be one place in the whole world where advanced sanitary law should be maintained it is in a large hotel. Yet they are, as a matter of fact, often built and maintained in defiance of the most ordinary rules of modern hygiene. What about the architect who is responsible for the plans of the hotel? Was he ignorant of the London County Council rules, or did he imagine that there would be no proper official inspection, or that at the worst any little difficulty would be got over by a complacent magistrate and a pliant vestry, and the payment of a paltry fine? Are we to understand that for the sum of ten guineas the proprietors of the Carlton Hotel are to be empowered to expose whole generations of visitors to the risks arising from inside soil-pipes? Surely, the magistrate's law must be wrong, and the County Council will not allow a salutary bye-law to be overridden in this fashion. Unless we mistake the character of the Council, further legal proceedings will be heard of in this matter, which has a distinct importance as a leading case.

Medical Men and Undertakers.

THE subject of the alleged commissions paid by undertakers to medical men for introducing custom is still attracting attention in the public Press, and in some journals has led to some correspondence. In the Birmingham Mail last week, for example, a writer signing himself "Lex," stated that in the course of winding up an estate in which he was interested, the executors exhausted most of their testator's ready cash in paying death dues, so the creditors were asked to let their claims stand over for a few months. With the exception of the undertakers all assented; he declined on the plea that he had already paid the medical man 10 per cent. on the amount of his bill which came to £80, for introducing the business. Perhaps before inditing this epistle it would have been more just if the correspondent had made some inquiries into the case, in order to ascertain whether the statements made by the undertaker were true. In any case, however, we trust that "Lex" will not refuse to give the names of the medical man and the tradesman to whom he refers when applied to by those who are inquiring into the authenticity of these alleged commissions. However, as an example of the other

side of the argument, a firm of undertakers wrote to the same newspaper last week, stating that they had been funeral directors for twenty-five years, during which period they had never once given a fee or commission to a medical man for introducing business. Owing to the publicity which this matter has received, it cannot be allowed to rest where it is, and in order to assist the inquiry all undertakers who have paid such commissions should not hesitate to come forward and say so, producing their evidence.

Foreign Bodies in the Vermiform Appendix.

SINCE the appendix has been treated surgically for its inflammatory disorders it has been found to contain a varied assortment of foreign bodies, together with fæcal concretions. In a paper in a recent number of the Johns Hopkins Hospital Bulletin, Mitchell discusses this subject from a statistical standpoint, and refers to 1,400 cases of appendicitis from various sources in the last ten years. In about seven per cent. of these cases true foreign bodies were found, while in 700 of the patients in the notes of whom a definite statement was made as to the nature of the foreign body, there were 45 per cent. of fæcal concretions. Among the assortment of foreign bodies which were brought to light mention is made of shot, pins, worms, gallstones, a tooth, and a piece of bone; also grape seeds and an oathusk, a date seed, five apple pips, and a bullet. Pins seem to have quite a predilection for the appendix. The author mentions thirty-five cases, of which he was able to obtain the record in which a pin was found in the appendix at the operation or the post-mortem examination, together with two instances in which a pin had perforated the cæcum. Contrary to what might be anticipated these cases occur more frequently in males than females, being chiefly in children under ten years of age. In only a single instance of the recorded cases was any information obtainable of the means by which the pin gained entrance to the body. Another interesting feature in connection with the cases was the comparative frequency with which they were associated with abscess of the liver. In eight out of the thirty-five cases this lesion was present. In summing up the result of his inquiries the author states that foreign bodies play a much smaller role than was thought to be the case formerly in the causation of appendicitis, while the most frequently exciting cause is fæcal concretion. Again, there was evidence to show that the appendix acted like a trap for pointed bodies or small heavy objects such as shot or bullets. Furthermore, the popular notion that foreign bodies of light weight, as for example, grape seeds and cherry stones, were a frequent cause of appendicitis was, as a matter of fact, erroneous, inasmuch as their presence in the appendix was exceptional. The author, therefore, believes that the pin is the commonest, and at the same time the most dangerous of all foreign bodies. Of the thirty-five cases in which a pin was found in the appendix, the notes of which are given in the paper, nine are attributed to an English source.

Stamp-lickers' Tongue.

OF a truth, the ways of disease are manifold, and it may well be said that the study of them furnishes to mankind one of the most ravelled as well as the most fascinating and comprehensive of all intellectual pursuits. What layman, for instance, would suspect that the unassuming postage stamp could become an active vehicle for the spread of deadly ailments? Yet so it is, and the name "stamp-lickers' tongue" has recently been brought to our notice by two distinguished medical men whose names are household words not only in the profession but also throughout the whole civilised world. It is known to the few that the common postage stamp owes its adhesiveness to the serum of the horse. It follows that the film drawn from such a source may, or even must, at times be charged with microbes of a more or less hurtful nature. Nor could a more direct means of introducing such undesirable visitors into the human body be conceived than that involved in the extremely unæsthetic operation of drawing the tongue across the back of a postage stamp. If a man licked a large number of stamps daily over a sufficiently long period of time the chances are he would set up cancer of that much-abused member. As it is, many mysterious invasions of the mucous membrane of the mouth may not unreasonably be ascribed to the far too familiar habit noted by our medical friends. By the way, would not "stamplickers' mouth" be a better title? The danger has long ago been recognised by the postal authorities of this country, who have placed dampers on the counters of the Post Office, and some years ago an ingenious little apparatus, invented by a lady, was much in vogue. Although not an ideal alternative, we would advise readers who have no choice to use a moistened finger in their future postal operations.

An Epidemic of Small-Pox.

THE first epidemic of small-pox, after the passing of the Act last year, has begun, and Hull is the centre of its outbreak. The disease first appeared in the east part of the town, and has now spread to the west and north-east portions thereof. Of course, everything is being done by the sanitary authorities to isolate the patients and stem the dissemination of the disease, but naturally much anxiety is felt among those responsible for the health of the town as to the position of affairs. On the other hand, it is satisfactory to report that the vaccination officers in some districts of the town are able to announce a large increase of cases of vaccination in their districts. One officer affirms that since the Act of last year came into force. and the time limit had expired, he had only had about ten cases of conscientious objection. The working classes in his experience did not object to vaccination, whereas the applications to the magistrates were principally from the middle classes. After all, with the glycerinated calf lymph now provided by the State, we cannot see that the anti-vaccinationists have a single plea left for urging their stupid fad. Mr. Chaplain says that the public have accepted the

new lymph as the solution to the problem, and that the new Act is exceeding all anticipations as a vaccination measure. We can only trust that what Mr. Chaplin says is true.

Alcoholism and Phthisis.

OF all the causes of chronic malnutrition which predispose to phthisis in adult life the abuse of alcohol is probably one of the most potent. The victims of the habit usually come under medical observation for dyspepsia associated with loss of appetite and more or less profound disturbance of the mechanism of nutrition. In the long run all the tissues of the body participate in the process of denutrition and their vitality is progressively impaired until they, or some of them, fall an easy prey to any form of infection which chance may throw in their way. Dr. Jacquet, in a paper recently read before the Paris Hospitals' Society on the relationship of alcoholism with phthisis, mentions that the history, in sixteen out of seventeen cases of phthisis in his wards, pointed to confirmed abuse of alcohol for years before the first symptoms of the pulmonary disease had made their appearance. He remarked, moreover that in alcoholic patients the second or disintegrating stage of the disease runs a very rapid course in spite of the fibroid tendency which is generally held to characterise the physiological effects of chronic alcoholism. It is more than probable that in many instances alcohol only intensifies an already existing predisposition, but this does not alter the fact that alcohol per se, especially when taken on an empty stomach or in the form of absinthe, is a potent factor in creating a tendency to tuberculous infection.

Caffein and Its Dangers.

THE employment of caffein in cardiac and renal disease has become very general during the last few years, but it is well to bear in mind that though capable of rendering great service under certain circumstances, it is a drug that requires to be administered with caution. Several well authenticated cases have been recorded in which the administration of caffein has determined sudden death even in the absence of any obvious organic lesion. In three cases recently published by Professor Zenetz, of Varsovia, the heart was found post-mortem so firmly contracted that it could with difficulty be sliced. In patients suffering from cardiorenal disease, the administration of from three to five grains of citrate of caffein twice or thrice daily, though it brought about increased diuresis and improved the action of the heart, ultimately caused a distinct change for the worse in the general condition, manifested by oppression, dyspnæa and nocturnal excitement, the area of dulness of the heart at the same time undergoing very perceptible diminution. It was noted that traces of caffein could be found in the urine for a period of from ten to fifteen days after ceasing its administration. This shows that caffein is eliminated but slowly by the kidneys, and the dangerous effects to which we have called attention are probably due to its accumulation within the organism.

The Saturday Hospital Fund.

THE Committee of the London Hospital Saturday Fund has issued its twenty-fifth annual report. Its financial position is satisfactory, and the receipts advanced steadily from £4.141 in 1874, to £20,113 in 1898. The falling off in the last mentioned year when compared with 1897 is explained by the radical and most desirable change that has been effected in the organising methods by doing away with the street collec-Notwithstanding the loss that ensued, the Fund may be congratulated upon the fact that the total amount available for grants was diminished only by the comparatively trifling sum of £600. In many ways we regard this Saturday Fund as one of the soundest charitable institutions in Great Britain. At the same time we have always felt it our duty to protest against some of the proceedings of the management. We note, for instance, in the list of institutions connected with the Fund, the name of a Convalescent Home that for years past has laboured, and is still labouring, under grave public charges of mismanagement. We also note the official connection of the Fund with the Metropolitan Provident Medical Association, a connection that always seemed to us to give an undue preference, to say nothing of money payments, to a selected number of medical men. The great loss of the year has been the resignation of Mr. R. B. D. Acland, who for nine years has steered a difficult course with tact and ability whom it will indeed be difficult to replace. It is to be hoped and believed, however, that the bark has been brought for a time into smoother water, notwithstanding the shoals and rocks of hospital reform that still lie ahead.

The Secret Commissions Bill.

LORD RUSSELL OF KILLOWEN introduced his Anticorruption Bill on the 20th ult. into the House of Lords, and garnished his statement with a reassertion of the fact that the medical profession are in the habit of receiving secret commissions from chemists, opticians, and even undertakers. Speaking for the medical profession, we desire every success for any Bill which will make impossible such disreputable proceeding on the part of medical practitioners, but we protest against the Lord Chief Justice or the London Chamber of Commerce, or anyone else making a charge which they, so far, have not made any attempt to prove, and, we believe, cannot prove. We absolutely deny that the acceptance of secret commissions from chemists or opticians exists among even a material fraction of the members of the profession, though, of course, we assume that a few of the helots resort to the practice just as they descend to any other disreputable proceeding. We should like to see Lord Russell's Bill submitted to a Select Committee, when the two chemists and one optician, upon whose hearsay testimony the charge is made. could be put at the witness table and thoroughly examined.

[Our Edinburgh correspondent refers to this subject in another column, as it is supposed to affect Scotland.]

An Old English Work.

A REMARKABLE Old English MS. on Medicine was sold at Messrs. Sotheby's last week. It was the work of Guy de Chauliac, a great medical authority in the Middle Ages, who helped to fight the plague. Some of this physician's prescriptions are still in existence. The book, which is clearly written in black letter, is entitled in the quaint style of the period: "Here begiiney ye Inventorie or ye Collectoriie in Cirgurgicale part of Medicene, compiled and complete i ye zere of Oure Lord 1363 by Guydone I Gy de Caulviaco, Cyrugien, Maistr in Medicene, doctor of Phisic, in ye ful clere studie of Montis Pessulani, Montpelers wt. som addicons of oth. doctourez necessary to ye foresaid Arte or Crafte." The MS. has fourteen fine ornamental painted and illuminated initials, with floreate marginal decorations and drawings of surgical instruments. The surgical works of Guy de Chauliac written in 1363 were first printed in French in 1478. in Latin (with other medical writers) in 1498, afterwards appearing in Italian and Spanish, but no English translation has apparently ever been printed. This important MS. was once submitted to the late Sir Andrew Clark, who was of opinion that its reproduction would be of great value to the medical profession.

The Disposal of the Dead.

THE problem of how to find space for the disposal of the dead in the metropolitan area is one which in a few years more will have reached an acute stage-Cemeteries are not unlimited, expansible areasand the limit of their expansion in London seems to have been reached. No further ground, then, being available for the burial, within the district, of London's dead, it is obvious that the problem will have to be solved by finding burial accommodation elsewhere. One difficulty, however which will be ever present in this regard will be that Londoners will be likely to rebel of sentiment. against being called upon to take their dead kith and kin to be buried in districts far removed from their everyday surroundings, and whither pilgrimages would be costly and demand a large expenditure of But in the interests of the public health, sentiment notwithstanding, London's burial places should be far away from the living, if in after years the salubrity of the metropolis is to be maintained.

A Municipal Doctor for Dublin.

THE Daily Independent says that it has been decided that the Corporation shall appoint a Municipal Doctor. It speculates as to the duties which the official will have to discharge, and protests against a job to be perpetrated for the benefit of some unknown individual. We confess to having no information on the subject, but we entirely sympathise with such protest.

Lunatic Asylum Discipline.

THE difficulty which medical superintendents of

from outrage and to maintain discipline among the staff is illustrated by a recent prosecution in Cork of a warder for kicking a lunatic. In most of these cases there is cross-swearing, with the usual allowance for perjury, but, in this instance, the attendant was caught by the Assistant Resident not only kicking the patient on the floor, but kicking him in the presence of a crowd of inmates. The only defence was that the lunatic, who was epileptic, kicked out and hurt the attendant, but we might ask of what use is an attendant if he cannot stand the violence of a patient without knocking him down and kicking him. The useful lesson to be derived from the proceedings is in the fact that, after the ruffian had been caught in the very act, the sapient magistrates considered half-a-sovereign a sufficient penalty for his offence.

The London Medical Graduates' College and Polyclinic.

THE prospectus of the new Polyclinic College in London has just been issued, containing a full list of the post-graduate educational course for the first session which commenced on the 1st instant. The list comprises practical classes, lectures, and laboratory and clinical classes, and each course will extend over six weeks. In addition, during the current month, clinical consultations will be held at the Polyclinic on three afternoons in each week. The "bill of fare," so far, is certainly an attractive one, catering, as it does, for all the possible requirements of the post-graduate student. It may be said, therefore, that the Polyclinic starts its career auspiciously, and should have a successful future.

Nurse Training for Irish Workhouses.

MR. EDWARD THOMPSON, surgeon to the Tyrone County Infirmary, has been making a good deal of newspaper noise because the Local Government Board declines to recognise the training of nurses in county infirmaries as sufficient for the Poor-law service. We quite admit that there may be infirmaries which are able to give their nurses a good and sufficient training, but we know that these are the exception, and we can understand that the Local Government Board can scarcely be asked to make a selection among these institutions. Wherefore there seems to be no course open to them but to adhere to the recognition of fully equipped clinical hospitals only.

"Dr. Bland," Limited.

THE question of the right of a syndicate of unqualified persons to carry on a joint stock doctoring speculation is receiving immediate illustration in Dublin. A company has been formed, of which the first subscribers are five pharmaceutical chemists, a clerk, and a gentleman named Whelan, who is described as a physician and surgeon. It proposes to "carry on the professions or businesses of medical asylums suffer in their efforts to protect the patients doctors, physicians, apothecaries, pharmaceutical

chemists, dentists, midwives, and druggists." The programme is sufficiently comprehensive and, if the formation of the company be proceeded with, the legality of its proceedings will need to be carefully watched.

A MAN named Walter Fisher, of Sprowston, near Norwich, was sent to prison last week for six weeks, for having on March 28th last, deposited for sale at Smithfield Market, four quarters of beef which were diseased and unfit for human food.

THE following appeared in the Times of April 28th: -" The results attained by the experiments with inoculation against enteric fever in India have been so satisfactory that there is every hope that the scourge, if not eliminated, will be so brought under control that the mortality caused by it in our Army abroad will be reduced to a minimum."

THE Royal College of Physicians of London has been presented by the executors of the late Dr. Hare with a gold angel piece of the time of Charles II, given to persons "touched" by the King for the King's evil.

A CHEQUE for £1,000, as a donation to the Prince of Wales's Hospital Fund, has been received from Mr. J. B. Robinson. This is the second contribution of one thousand pounds received last week.

PERSONAL.

THE services of the English nurses in the Greek hospitals during the Turko-Greek war have been recognised by the Queen of the Hellenes by the grant to them of a medal and special diploma.

SIR WILLIAM TURNER, President of the General Medical Council, received the degree of Doctor of Science (honoris causa) at the University of Cambridge on the 27th ult.

HER MAJESTY THE QUEEN has presented Dr. Allen Sturge, of Nice, with a silver inkstand and writing materials in recognition of services rendered during her sojourn in the Riviera.

Dr. Dolan (Halifax) and Dr. Barr (Liverpool) have been appointed by the British Medical Association delegates to the Annual Congress of the Royal Institute of Public Health.

The Laboratories Committee of the Conjoint Board for England has appointed Dr. Thomas Grigor Brodie (lecturer on physiology at St. Thomas's Hospital) to fill the vacancy of director of the laboratories of the two colleges, void by the resignation of Dr. Sims Woodhead.

H.R.H. THE PRINCE OF WALES has appointed Sir Hermann Weber, Dr. Hillier, Mr. Malcolm Morris, and Mr. Rube as the representatives from this country of the National Association for the Prevention of Consumption and other forms of tuberculosis at the forthcoming Berlin Congress.

MAJOR RONALD Ross, I.M.S., whose name is wellknown in connection with his researches bearing on the role of the mosquito in the dissemination of malaria, arrived in London a few days since to take up his appointment as lecturer at the School for Tropical Diseases at Liverpool.

WE are pleased to learn that the health of Professor A. M. Buchanan has so much improved that he hopes to resume his teaching in the anatomical classes at Anderson's College, Glasgow, during the winter session. In the interim the lectures will be carried on by Dr. Howat, who has so successfully conducted the classes during Dr. Buchanan's prolonged illness.

MR. EDMUND OWEN, Past Master of Sancta Maria Lodge, and Mr. W. J. Walsham, Past Master of Rahere Lodge, were among those especially chosen by the Most Worshipful Grand Master, H.R.H. the Prince of Wales. to mark the twenty-fifth consecutive year of his office, the dignity of Past Grand Deacon having been conferred upon them.

THE Right Hon. Joseph Chamberlain, Secretary of State for the Colonies, will preside at the inauguration dinner of the London School of Tropical Medicine, on Friday the 10th inst., when a large and distinguished company is expected. The names of the dinner committee and other particulars will be found on reference to our advertising columns.

WE are glad to chronicle an act of gratitude on the part of a patient to his medical attendant. Mr. Thos. A. Matthieson, of Glasgow, whose will was proved last week, has bequeathed £500 to Dr. Samson Gemmell "for his kind attention during his professional attendance." He also left £500 to Anderson's College to assist the income of the Professor of Anatomy, and £250 each to the Glasgow Royal and Western Infirmaries.

Scotland.

FROM OUR OWN CORRESPONDENT.

SECRET COMMISSIONS .- Although the hands of the medical profession are probably somewhat cleaner in this respect than those of some of their neighbours, it is to be feared that dubious relations do sometimes exist between doctors and chemists. During the past week letters-anonymous, it is true-have appeared in the Scotsman newspaper, and there seems no reason to dispute their general accuracy. The writers, dispensing chemists, all tell the same tale. A "young" doctor (is it always the junior who wanders from virtue's ways?) calls, and proposes to the chemist that the latter is to dispense and to retain all the prescriptions of the former; that an account is to be kept of these, with the charges (which are to be in excess of the ordinary ones); and that the doctor is to get 30 to 40 per cent. of the profits of the "deal." From the doctor's point of view profits of the "deal." From the doctor's point of view this may be all very well; but the reflection that occurs to one is that the chemist must be very confiding who supposes that even the whole custom of a doctor just starting in practice will prove a lucrative investment. Of course there are all grades of this sort of thing. One hears, on the one hand, of the chemist from whom it is difficult to get a regular account of your indebtedness; on the other, of the doctor who never dreams of taking any notice of his drug bills. But, so far as our experience goes, it does not seem to be very prevalent; we are sure that the vast majority of medical men, here as elsewhere, can honestly disavow all knowledge of such practices. Possibly on account of the naked simplicity of our northern funeral rites, those other unholy alliancesbetween doctors and undertakers-do not appear to

exist here at all. Yet, surely we have met these undertakers somewhere. Does one's memory not fly back to the pact between Mr. Mould and one Sairey Gamp, of whom he said "She's the sort of woman now one would almost feel inclined to bury for nothing; and do it neatly, too!

THE WILL OF THE LATE SIR JOHN STRUTHERS.—By a codicil to his will, dated February 20th, 1899, Sir John Struthers leaves the sum of £500 to the Royal College of Surgeons of Edinburgh for the purpose of founding a lecture to be delivered before the college every third year. The subject of the lecture may be any part of human or comparative anatomy, naked eye, microscopical, or embryological normal anatomy understood, not pathological. The lecture may consist of original unpublished work, may be an account of the progress of some branch of anatomical science, or may relate to the history of anatomy. The choice of a lecturer is unrestricted as to country or profession, but he must be one who "has done and published noteworthy original work in one of the above-mentioned departments of anatomy." To the University of Edinburgh is bequeathed the stock of anatomical drawings to be exclusively under the care of the Professor of Anatomy. In this bequest the testator says, "The making of them (the drawings) has been a pleasure to me over many years, and I cannot now render them more useful than by presenting them for use in the anatomical class of Edinburgh University." A third bequest runs as follows:—"I leave £100 to the Royal Infirmary as a slight recognition of the benefit I derived from my connection with the old Royal Infirmary, in which I was dresser, non-resident surgical clerk, house physician, house surgeon, assistant surgeon, and junior ordinary surgeon from 1843 till 1863, when I went to Aberdeen, and in recognition of the honour and pleasure I have had since returning to Edinburgh in sitting on the board of management of the Royal Infirmary." £500 is bestowed on the University of Glasgow for the purpose of encouraging original work—not, it is expressly stated, for a students' prize in the ordinary sense. The award is to be biennial, the decision to rest with the Professor of Anatomy, and competition to be open to all students and graduates of the University, without respect

OPENING OF THE SUMMER SESSION IN GLASGOW. The University opened on the 25th ult., when there was a very large number of students present at the usual inaugural ceremonial. There was no introductory lecture here, or at any of the extra-mural schools. In each division the professor addressed a few remarks in the way of introduction to his students. Dr. Muir, the new Professor of Pathology, as was to be expected, received a warm and cordial reception from his students He told them that pathology is, of all branches of medical science, the most important. In this the new Professor is not singular, for have we not been told by every professor of the other branches of the science that his particular branch is the most important? The Professors of chemistry, anatomy, surgery, medicine, physiology, materia medica, therapeutics, pharmacology, midwifery, medical jurisprudence, natural history, &c., &c., invariably preface their teaching with, "Gentlemen, this is the most important branch of the science," &c.

Anderson's College also opened on the same day as the University, and the emoluments in the various classes give promise of totalling a considerably larger

number than in any previous year.

St. Mungo's College also opened on the 25th. Here also, a large number of students were enrolled and a further great addition is expected before the complete list of members is made up. In these schools no loss of time took place, as the work of the session began straight away.

QUEEN MARGARET COLLEGE FOR WOMEN also commenced on the same date, when all the classes were well attended. At the recent graduation ceremony the remale students were again located in the gallery, seeming to cause some friction among the young ladies. give them our sympathy, simply because elderly dowagers, who have no connection with the university, but simply from curiosity and love of show, are per-

mitted to occupy the area of the hall, so as to prevent the two sexes of students from mixing together and thus causing commotion and excitement among them.

Obituary.

DR. WILLIAM CARTE, OF DUBLIN.

THE lamented death of this gentleman deserves a much more sympathetic notice than the brief announcement which we published last week while our journal was at press. Dr. Carte took his first qualification as Licentiate of the Irish College of Surgeons in 1852, and subsequently became a Fellow in 1874, a member of its council, and its vice-president. Shortly after his qualifi-cation he entered the Army Medical Service, and went out to the Crimea, where he served with distinction during the greater part of the campaign, not only in the field but as a member of the official supervisory board. On his return home in 1857 he was appointed surgeon to on his return nome in 1007 he was appointed surgeon to the Royal Hospital for Old Soldiers at Kilmainham, which position he occupied at his death. He was also advanced to the Commission of the Peace for the county, and was chosen as surgeon to the County Gaol at Kilmainham, in which capacity his experiences were long and interesting. He had medical charge not only of Mr. Parnell and the other "suspects" who were incarcerated with that gentleman, but afterwards of the whole of the "Invincibles" who planned and executed the murders of Lord Frederick Cavendish and of Mr. Burke, the Under-Secretary, besides many of the local murders throughout the country, for which a dozen or so were hanged. Dr. William Carte shared with his brother, Dr. Alexander Carte, an ardent taste for natural history, and, possessing the faculty of neat manipulation and a good knowledge of dissecting, he assisted his brother and served for some time as curator of the Irish College of Surgeons. most important of his published papers had reference to comparative anatomy, which, we regret to say, seems likely to become a lost science in Ireland. In 1891 he was appointed Physician and Surgeon on the Staff of the Commander of the Forces.

Dr. Carte, of late years, went largely into public life as an administrator of public enterprises, and in that capacity showed not only great ability, but the indispensable attributes of integrity, discretion, and good address. His chief venture was in the Dublin Tramway Company, which under his chairmanship flourished so exceedingly as to be now one of the best investments available, and one of the Institutions of which Dublin has a right to be proud. When the electric installation now being substituted for horse traction is completed, no such perfect system of domestic locomotion will be found in Europe, Dr. Carte was also intimately associated with the management of the Blessington Tram-way Company, the Civil Service Building Society, and other stable and prosperous organisations. He was a gentleman in mind, and therefore necessarily, in manner, and he dies universally regretted, not only by his pro-fessional brethren, but by a very large circle which knew him as a public man.

DR. NEDLEY, OF DUBLIN.

THE death of this gentleman, which took place on the 25th ult., at his residence in Cavendish Row, Dublin, at the ripe age of 79, and, after long delicacy of health, is worthy of special notice, as he was a personality very well known and characteristic for the public as well as the profession.

Dr. Nedley took his first qualification as a Licentiate of the Edinburgh College of Surgeons in 1851, and became M.D. of King's College, Aberdeen, in 1856, and, for some years, he, being a man of marked ability, acquired and enjoyed a fair share of private practice, but he cannot be said to have been, in any other sense, a member of the medical fraternity. So far as we know he never wrote a line for publication, or read a paper on a professional subject, or belonged to any medical society even in name, or, in fact, associated himself with medical organisations in any way, or subscribed a shilling to their funds. It was to his gifts as a social entertainer that Dr. Nedley owed everything in life. He was a professed story-teller, and kept on hand a number of amusing anecdotes which he was wont to retail for the delectation of his friends at dinner and elsewhere, and, as he possessed some ready wit, and the faculty of imitating a variety of Irish brogues, his stories were always amusing, especially to English visitors, who listened with speechless wonder to his flights of fancy. He also possessed an excellent tenor voice for an amateur, and a considerable know-ledge of music, which caused his songs to be as popular as his stories. We should be only making his memory as a musician ridiculous if we were to adopt the fulsome gush of one of the Dublin newspapers, which said-"His tenor was as sweet as Guiglini's, and far more robust. His knowledge of music was incomparably greater. He could easily have made £10,000 a year as a singer, but for his unconquerable nervousness." These special qualities for entertaining the public were brought to the notice of the Earl of Carlisle in the year 1855, when that nobleman assumed the Viceroyalty, Nedley was forth. with invited to the select Castle dinners, as a unique specimen of the witty, wild, Irish native, and, forthwith, Lord Carlisle became so enamoured of Dr. Nedley's qualities that he showered upon him the first good thing at his disposal. He made him surgeon to the Metropolitan police; a lucrative position, which he vacated only about a year ago. He was also, on the death of Dr. James Stannus Hughes, appointed surgeon to the Viceregal Household, the only medical Household appointment which carries with it a salary. He has recently been succeeded in that office by Mr. Lentaigne. He was also Medical Attendant on the Training School attached to the National Board of Education.

Parliamentary Aews.

THE MIDWIVES BILL came up for discussion on Tuesday of last week on the motion for its second reading, but Sir Walter Foster objected, and the discussion was

adjourned until Monday last.

INEBRIATE REFORMATORIES.—The Home Secretary stated that three inebriate reformatories had been certified, but that no local authority had as yet established any such institution, though the matter was under consideration by several municipalities. There being no certified reformatory for men, several men have had to be discharged for want of such accommodation. With one exception the reformatories certified are willing to receive persons committed under Section 1 of the Act. Later in the week the Home Secretary in reply, to Mr. Hobhouse, said that he did not feel justified at present in setting up a State reformatory for inebriates, but substantial Government contributions had been secured for persons committed to certified reformatories. He proposes later on to call the special attention of the local authorities to their responsibility in the matter.

THE TEETH OF RECRUITS.—In reply to a question, it was stated that in 1898 no fewer than 1,767 recruits were rejected on account of the unsatisfactory condition of

their dental appendages.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

MEDICAL AID ASSOCIATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—There are two sides to every question, and I beg herewith to advance a few considerations for the behoof of the two general practitioners who have lately trumpeted so loudly in the correspondence columns of your valuable journal.

First, and foremost, if I, a properly qualified and registered medical practitioner, choose to accept the salary offered by a certain combination of individuals

who is to say me nay? The amount of the salary has nothing to do with the question. Otherwise who is to defend the ridiculous sums paid to house surgeons, qualified assistants, junior officers (and, for that matter, of the senior officers as well), in workhouses and in lunatic asylums? Our opponents say that the medical aid system is radically wrong, because it makes a profit out of a medical man to whom a fixed salary is raid.

Now, Sir, may I ask your heated correspondents in what respect a medical aid officer differs from a junior medical assistant at a private asylum, paid at, say, £100 per annum, a sum that the average medical aid officer would despise. A plain answer to this point would serve to demonstrate to those who now cry out so loudly that the beam is not so far remote from their own organ of vision. The assistant lunacy officer is a qualified registered practitioner, engaged at a peddling rate to put profit in the pockets of his employers, the fat private asylum proprietors.

There are other points that could be raised with equal force and logic, but for the time being the point I have advanced will suffice. I challenge any of your readers to offer me a satisfactory way out of the above discusses.

to offer me a satisfactory way out of the above dilemma.

As to interference by the General Medical Council, the idea is too absurd for discussion in the columns of a serious journal.

I am, Sir, yours truly,
April 22nd, 1899.

MEDICAL AID OFFICER.

MORTALITY UNDER ANÆSTHETICS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR SIR,—Some coroners are in the habit of consoling the relatives of the victims of maladministration of an anæsthetic mishap with the assurance that the mortality under chloroform is 1 in 4,000 cases; under A.C.E. and other mixtures containing chloroform, 1 in 6,000; while under ether, which is asserted to be an anæsthetic eight times safer than chloroform, the proportion is only 1 in 32,000; under nitrous oxide, said to be practically free

from all risk, it is put at 1 in 1,000,000.

If these statistics are based upon facts, some interesting results may be deduced from the returns for the year 1897. During this period, 96 inquests were held on persons who had died under anæsthetics in England

alone, viz., 63 males and 33 females.

Fron	n pure chloroform A.C.E. and other mixtures contain	 nino	74	deaths.
"	chloroform		10	,,
,,	Pure ether Nitrous oxide followed by ether	•••	4	"
"	Mitrous oxide followed by ether	•••	5	"
	Total		96	

If the mortality statistics under anæsthetics quoted above are based upon facts, it follows, that in the year 1897 the following number of surgical operations performed under an anæsthetic in England alone must have been as follows:—

					0
Under	chloroform				Operations. 296,000
,,	mixtures con	60,000			
,,	ether		•••		224,000
,,	nitrous oxide	•	•••		7,000,000
			Tot	tal ·	7.580.000

Quod absurdum est. Seriously, however, as the name of the anæsthetist in all fatal cases is known it ought to be possible to obtain trustworthy information (1) on the total number of cases in which the particular anæsthetist has administered either of the four principal anæsthetic agents or combinations; (2) the number of times he has administered them during the year 1897.

I may point out that the deaths under anæsthetics reported in the daily papers probably represent but a fraction of the total number. Dr. Leonard Hill recently remarked that: "In a certain institution in Great Britain, in the course of a recent year, not fewer than twelve deaths occurred. This is no exceptional case, the deaths from chloroform are not recorded in the medical journals,

for these reflect upon the reputation of the administrator and the institution in which they occur" (Brit. Med. Journal, April 17th, 1897). Professor Augustus Waller says in the same journal (November 10th, 1897): "A large proportion of the cases of death, undoubtedly caused by chloroform, are never published, How large a proportion it is impossible to say, yet almost certainly the largest proportion of the total number of deaths. At one hospital, from which two deaths from chloroform were reported during a year, nine deaths actually occurred." And Professor Juliard, of Geneva, gives particulars of twenty cases of death by chloroform that took place within his knowledge, but outside his own practice, three only of which had been published. In view of these facts it is fair to assume that the numbers given may safely be doubled.

I am, Sir, yours truly,
A Pisciple of John Snow.

Literature.

POLAND ON THE EPIPHYSES. (a)

This monumental monograph affords an interesting illustration of the more detailed knowledge that is being attained as scientific surgery approaches its maturer growth. The main volume contains some 900 pages of royal octavo size, and is supplemented by a small skiagraphic atlas showing the development of the bones of the wrist and hand. The little auxiliary volume strikes the keynote of the author's fresh departure in relation of the traumatic separation of the epiphyses. By the aid of the Röntgen rays he has studied recent and old injuries of the kind indicated, and has been thus enabled to ascertain definitely the condition of parts, whereas previously the only control over conjecture was the objective proof offered in comparatively rare instances by operation and by dissected museum specimens. Although the author has availed himself fully of the X-ray methods, he has also turned to the literature and the clinical aspects of the subject with an application that may be styled without any stretch of rhetoric as simply Gargantuan. Hitherto there has been no authoritative teaching of this important subject as a whole, and the practitioner has been left to a great extent to work out for himself the occurrence and the results of epiphyseal damage. Still, a knowledge of the signs of epiphysitis should now be in the grasp of every medical man, who would be thereby enabled to avoid many of the opprobria of surgery. The study of the traumatic conditions of the epiphyses has yielded conspicuously brilliant results in orthopedic surgery, in which Mr. Polland's monograph may be fairly said to mark a new era. To take an illustration of the bearing of this class of injury upon deformities, out of several instances of subsequent shortening of the humerus, the three following may be quoted. A woman, et. 30, whose humerus was shortened 5 ins. from a fall on shoulder in infancy. A woman of seventy with 3 ins. of shortening, due to an injury when six months old. A first case (Tubby's) of 3½ ins. of shortening in a lady of twenty-five, from being lifted up by the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks of a first or the arm at three weeks or by the arm at three years of age. Including the above. seven authentic cases of arrest of growth following separation of the upper epiphysis of the humerus are tabulated. The injuries to other long bones are treated at such length and minuteness as to render it out of the question to attempt any general sketch or summary of conclusions. The author has been fortunate in being able to complete his work with the fuller light thrown upon the subject by the Röntgen methods. Indeed, without that aid much of the present volume could not have been written. Many of the radiograms have been furnished by Messrs. Webster and Thos. Moore, two well-known workers in this field. The wide range between the appearance of some of the centres of ossification is shown in the Atlas by the cuneiform bone of the carpus, which is visible in the radiogram of a child

(a) "Traumatic Separation of the Epiphyses." By John Poland, F.R.C.S. London: Smith, Elder & Co. 1898. Price £2 12s. 6d.

of two, but absent in another from one of aged three and from a third five years of age. As a book of reference, Mr. Poland's exhaustive 'monograph will be essential to the shelves of every medical library no less than of every scientific surgeon. The labour involved must have been very great, even if we take the simple verification of references. The editing and the general appearance of the book are excellent, and the matter is illustrated with no less than three hundred and thirty-seven illustrations. The work savours of the German love of absolute and comprehensive detail, but at the same time it is tempered with an insular blending of the practical. The book is a credit to English surgery and all concerned in its production deserve the thanks of the medical profession.

Aew Enstruments.

AN IMPROVED FORM OF AXIS-TRACTION FORCEPS.

Messas. Down Brothers, of St. Thomas's Street, SE., have enabled us to make a practical test of an improved form of axis-traction forceps, the outcome of twelve months' experiments at the hands of Dr. G. Porter Mathew. The advantages which axis-traction forceps possess over the instrument in general use are, even now, not as generally appreciated in this country as their importance merits. No one who has studied their use would be disposed to question the value of Professor Tarnier's innovation. These forceps enable powerful traction to be applied in the axis of the pelvic canal without the risk of any misapplication of force and consequent damage to mother and child. They look a wee bit complicated, but this is only because to many practitioners they are unfamiliar, and a very small amount of practice effectually disposes of any diffidence on this ground.

on this ground. Dr. Mathew's forceps differ from other axis-traction forceps in several noteworthy points. They are made entirely of metal, and can be sterilised by boiling. The traction rods are detachable, and are easily cleansed and the weight has been brought as low as is consistent with perfect rigidity. There are no screws or fixed joints, except in the parts that remain outside the vulva, and such screws as are present, few in number, are not easily lost. The blades have a pelvic curve of a seven-inch radius, and the cephalic curve is also more abrupt rigid though somewhat narrower than ordinary blades. The lock is the close-fitting ordinary Englsh lock. The application handles have been much shortthan usual. The blades are stout and

much snortened and lightened, and once
the blades
have been
applied they
become merely
"indicators."
The traction
rods are on
the wellknown rect-

angular model, devised by Dr. Milne Murray, and they are easily detachable by an aseptic joint. A special form of traction block has beendevised by Messrs. Down Brothers, which combines the qualities of lightness, ease of application and facility of cleansing, with an absence of screws which might be mislaid or lost.

These forceps afford a good example of the perfection to which the manufacture of surgical instruments has been brought in this country. They are admirably finished, neat in appearance, and rigid in use. In the

interests of the parturient population it is to be hoped that obstetricians will, in future, avail themselves more generally of the advantages of the form of midwifery forceps, for many a difficult labour would be simplified, and many a perineum saved from rupture.

Medical Aews and Pass Lists.

Royal College of Physicians of London.

Ar the ordinary quarterly comitia of the College, held last week, the following members were elected Fellows of the College: -

Sydney A. Monckton Copeman, M.A., M.D.Camb; Wilfred James Hadley, M.D.Durh; Henry Handford, M.D., C.M.Ed.; Percival Horton-smith, M.A., M.D.Camb.; Cyril Ogle, M.A., M.B.Oxon.; Arthur Ransome, M.A., M.D.Camb.; William Halse Rivers Rivers, M.A. (hon. causa), Camb., M.D.Lond, William John Ritchle Simpson, M.D.Aberd.; William Vicary Snow, M.D.Lond.; Herbert Ritchle Spencer, M.D.Lond.

The following gentlemen having passed the required examinations and conformed to the by-laws were admitted Members of the College:-

Peverell Smythe Hichens, M.A., M.B., B.Ch.Oxf., L.R.C.P. and M.R.C.S.; and George Thornton, M.D., C.M.Edin., L.R.C.P. and M.R.C.S.; Arthur Latham Ormerod, M.A., M.B Oxf. L.R.C.P. and M.R.C.S.

At this meeting various reports were received, and the usual routine business transacted. It was also decided to recognise the Royal University of Ireland as one of the Universities whose students are entitled to exemption from the first and second examinations of the conjoint board, and to continue during the present year, the recognition of the late Mr. Thos. Cooke's School of Anatomy, as previously.

Royal University of Ireland.—Second Medical Examination

Upper Pass.—Robert J. Bethune, Q. C., Belfast; Thomas A. Carson, Q. C., Belfast; Walter Phillips, B.A., Q. C., 'Belfast; Edward T. Tuckey, Q.C., Cork; Thomas Walsh, Q. C., Galway, and John S. P. Weir, Q. C., Belfast. Above may present themselves for

Honours.

Pass.—Marion B. Andrews, Q. C., Belfast; Robert Best, Q. C., Galway; Catharine L. Boyd, Q. C., Belfast; William H. N. Bright, Q. C., Belfast; James G. Campbell, Q. C., Belfast; Joseph Corker, Q. C., Belfast; James G. Campbell, Q. C., Belfast; Joseph Corker, Q. C., Cork; Elizabeth S. Graham, Q. C., Belfast; Rodolphus W. Harper, Q. C., Belfast; Patrick Heffernan, Cath. Univ.; Michael J. Zaffan, B. A., Cath. Univ.; John L. Lunham, Q. C., Cork; Maurice J. Macauley, Q. C., Cork; John McClatchey, Q. C., Belfast; Samuel B. W. Moore, Q. C., Belfast; Andrew J. Quirk, Cath. Univ.; Jane E. Reynolds, Q. C., Cork; Frederick W. Stewart, Q. C., Belfast; and William A. Stoops, B.A., Q. C., Belfast.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.

AT the April sittings of the Conjoint Board held in Glasgow, the following candidates passed the respective examinations :-

First Examination (five years' course): William George Macdonald (with distinction), Edward Graham Taylor, Thomas Percy Cox, Evan Owen Roberts, William John Shorten, William Francis Holland, James M'Manus, Edward P. A. Richardson, D. Bernard William Dakers, William S. Nicholson, Samuel Robert Scott, Edmund Eccles.

First Examination (four years' course): Thomas B. Trotter, George A. M'Farland, Thomas Arthur Fall.

George A. M'Farland, Thomas Arthur Fall.

Second Examination (five years' course): John M'Intyre (with distinction), John Wm. Isbister, Syed Zumiruddin, Wm. Thomson, James Charles Galloway, Adam Fox, Archibald Macmillan (with distinction), Archibald B. Laidlaw, William H. Duncan, James W. Skelly, John Stewart, Ashton N. Collier, John Raeside Smith (with distinction), Stuart Jackson Farries, Terence Aloysius Welch, Charles Henry Nash, Joseph Edwin Cooper.

Second Examination (four years' course): Robert Cooper, Hamilton Jos. Bell, B.A., Robert Dunlop, William Boyd, Joseph D. Bepley.

Hamilton Jos. Bell, B.A., Robert Dunlop, William Boyd, Joseph D. Begley.
Third Examination: Alexander Scoular (with distinction); Percival H. Rainbird; Charles W. Sharp; Peter Mackellar Dewar; Alexander Fraser Jack; John Thomson Mallock; Allan Douglas Cameron; Timothy M. O'Driscoll: Ernest George Dryden Benson; Eyre William Powell; Paresh R. Roy.
Final Examination (and admitted licentiates of the three co operating colleges): James M. Inverarity; William M'Farlane; Alexander Johnston Wilson; Richard Steward (with honours); Duncan Macpherson Macgregor, William Denness: Louise Alice Fox; Joseph V. Usher-Summers; George Abraham Parker; Edgar Hepworth Alton; Andrew Snody Omund; Ernest Hill; Samuel Howard Smith; Devis Murphy: Margaret Elizabeth M'Neill; Albert Sophron Sieger; George Phocion Barff, John Wiglesworth.

Meath Hospital and Co. Dublin Infirmary.

At the annual prize examinations in this institution senior prizes in clinical medicine and surgery, were awarded to Mr. Edmund Bennett (gold medal), and to art" with a vengeance!

Mr. Patrick S. O'Reilly (silver medal); the junior prize fell to Mr. Byrne.

Small-Pox Patients at Hull.

THE steamer, Port Darwen, of London, arrived at Hull on Sunday morning having six cases of small-pox on board. The vessel was from Alexandria, and she had as passengers an English minister, his wife and sister, and seven children. A few days out the minister was taken ill, the illness developed into small-pox, and he died before Algiers was reached, the body being buried at sea. After Gibraltar had been passed five of the children took the disease, and also the steward who had attended them. On the vessel arriving at Hull the patients were landed and conveyed to the hospital, and the ship was disinfected.

Corporate and Medical Reform Association, Limited.

At a meeting of the Executive Committee, held on the 22nd ult., the following resolutions were unani-mously adopted:—1. That the letter of the President of Council and Honorary Secretaries to the Lord President of the Privy Council, with the reply received, be sent to the Direct Representatives, with covering resolutions urging them to press home the five objections to the present Midwives Bill taken in the letter to the Lord President:—(1) That the Bill confers the right to attend all cases of labour; (2) also the right to render all attendance, including use of medicine and instruments; (3) that rights conferred by Statute cannot be taken away or diminished by a board formed to regulate the exercise of the rights; (4) that central licensing and a national roll (as provided in the Bill) override local authority and place the midwife beyond control; (5) that in all these respects the Bill fails to comply with the recommendations of the General Medical Council. A committee was constituted, consisting of members of the association, who are also members of the Ophthalmological Society U.K., and a letter of that committee adopted, inviting the support of other members of the Ophthalmological Society in opposing the certification unqualified persons as efficient in departments of medical practice.

Mortality in Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Bombay 142, Madras 35, Paris 23, Brussels 17, Amsterdam 18, Rotterdam 19, The Hague 20, Copenhagen 18, Stockholm 23, Christiania 16, St. Petersburg 26, Moscow 26, Berlin 20, Hamburg 16, Dresden 21, Breslau 27, Munich 26, Vienna 24, Prague 30, Buda-Pesth 26, Trieste —, Rome 20, Venice 31, Cairo —, Alexandria —, New York (including Brooklyn) -, Philadelphia 20.

THE New York Assembly has passed a Bill providing that a witness shall in future lay his hand on the Bible, instead of kissing it, while the oath is being administered. If the witness be allowed to wear gloves the sole remaining risk of contracting scabies will have been obviated.

THE Governor of New York has signed the Bill passed by the Legislature prohibiting bicycle racing for a greater period than twelve hours in any period of twenty-four hours.

THE Boston Medical and Surgical Journal states that as a result of the inquest on the person who was poisoned by cyanide of mercury sent in a bottle of "Kutnow Powder," the firm engaged in manufacturing this quack medicine has been forced into bankruptcy, consequent upon the falling off in the sales.

THE Civil Code in force at New York has been reinforced by a provision forbidding physicians to give any information concerning the mental or physical condition of his patient either before or after the death of the latter. No exception is made in favour of persons whose life is insured.

A well-known American musical composer has undertaken, in exchange for £1,000, to compose a march to bear the name of a certain proprietary medicine, and to be used in advertising the same. This is "art for

CENTRAL LONDON THROAT AND EAR HOSPITAL.-5 p.m. Mr. Lennox Browne's Lecture on Ozena.

Bacancies.

Aston Union.—Resident Assistant Medical Officer at the Workhouse, Erdington, near Birmingham. Salary £100 per annum, with furnished apartments, rations, washing, &c.

Barnwood House Hospital for the Insane, Gloucester.—Junior Assistant Medical Officer. Salary £100 per annum, rising to £120 after the first year, with board, &c.

Berks County Asylum, Wallingford.—Junior Assistant Medical Officer, unmarried. Salary commencing at £120 per annum, with furnished apartments, board, attendance, and washing.

Bethlem Hospital.—Two Resident House Physicians for six months. Apartments, complete board and washing provided, and an honorarium at the rate of £12 12s. each per quarter will be paid. Applications to the Treasurer, Bridewell Hospital, New Bridge Street, London, E.C. (See Advert.)

County Asylum, Shrewsbury.—Junior Assistant Medical Officer, Salary commencing at £130 per annum, rising £10 a year to £150, with board, lodging, and washing (no liquors).

Dublin, Cork Street Fever Hospital.—Assistant Registrar and Resident Medical Officer. Salary £46 per annum, with board, resident Medical Officer.

dence, and attendance. Immediate applications to the Chairman. (See Advt.)
Grove Hall Asylum Bow, E.—Junior Assistant Medical Officer.
Salary £120 per annum, with board, lodging, and washing.
Personal application to the Medical Superintendent.
Manchester Roval Infirmary.—Honorary Ophthalmic Surgeon and an Honorary Assistant Physician. Applications to W. L.
Saunder, Esq., Secretary, on or before May 20th. (See Advt.)
Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments in the hospital.

Rural and Urban Districts in the Counties of Leicester, Rutland, and Warwick.—Medical Officer of Health for the period ending June, 30th, 1902. Salary £450 per annum, inclusive of travelling, stationery, and other expenses. Applications to the Clerk to the Joint Committee, Lutterworth.

Stepney Union. Medical Officer for the Union Workhouse, 15t.
Leonard's Street, Bromley-by-Bow, E.—Salary commencing at £110 per annum, with the usual midwifery and vaccination fees in addition. Applications to the Clerk, Offices, Barnes Street, Ratcliffe, E.

Appointments.

ADAMS, D. V. M., M.B., Ch.B.Edin., a Resident Surgeon to the Glasgow Royal Infirmary.

BATEMAN, F. J. HARVEY, B.A.Cantab., M.B., C.M.Rdin., House Surgeon to the Leith Hospital.

BAUMANN, E. P., M.B., Ch.B.Edin., M.R.C. S., L.R.C.P.Lond., Resident Physician to the Glasgow Royal Infirmary.

CAMERON, A. F., M.B., C.M.Edin., Resident Assistant Medical Officer for the Workhouse of the Sheffield Union.

CHRISTIE, B. B., CRAIG, M.B., C.M.Edin., a Resident Physician to the Glasgow Royal Infirmary.

GRIFFITHS, JOHN S., M.B.C.S., L.R.C.P., Medical Officer to the Bristol Jubilee Convalescent Home.

GRIMSDALE, HAROLD B., M. B., B.C.Cantab., F.R.C.S. Eng., Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

HECTOR, C. MUNRO, M.D.Edin., Demonstrator of Bacteriology, University College, Sheffield.

JELLET, W. E., M.B., Ch.B.Edin., a Resident Surgeon to the Glasgow Royal Infirmary.

JORDAN, H., MARTYN, F.R.C.S., Registrar to the Chelsea Hospital for Women.

SALMOND, J. L., M.B., C.M.Aberd., Medical Officer to the Aberdeen Dispensary, Vaccine, and Maternity Hospital.

THOMAS, J. T., L.R.C.P. Irel., L.R.C.S.Edin., D.P.H.Irel., Medical Officer of Health for Wiltshire.

WILSON, A. GARRICK, M.R.C.S., L.R.C.P., Junior Out-patient Surgical Officer to the Royal London Ophthalmic Hospital, Moorfields.

Births.

BERRY.- On April 26th, at South Lowestoft, the wife of Walter Berry, M.D., of a son.

Stewart.- On April 36th, at Walton House, Lordship Lane, S.E., the wife of H. M. Stewart, M.D.Cantab., of a son.

WALKER.--On April 27th, at Hill Road, Wimbledon, the wife of George Walker, M.R.C.S., L.R.C.P., of a son, stillborn.

Marriages.

BLAND SUTTON—HEATHER BIGG.—On April 21st, at St. Marylebone Church, London, John Bland Sutton, F.R.C.S., to Edith, youngest daughter of Mrs. Heather Bigg, of Radnor Place, W.

BROWN—NORTH.—On April 26th, at the Church of St. John the Evangelist, Upper Norwood, David Brown, B.Sc., M.D.Lond., of Taunton, to Ceciha Emily, elder daughter of George North, of Upper Norwood.

LYDALL—WATKIN.—On April 27th, at the Parish Church, Wellingborough, Wykeham Tracy Lydall, M.D., of Birmingham, to Gertrude Watkin, eldest daughter of Charles Watkin, Esq., of Wellingborough.

Gertrude Watkin, eldest daughter of Charles Watkin, Esq., of Wellingborough.

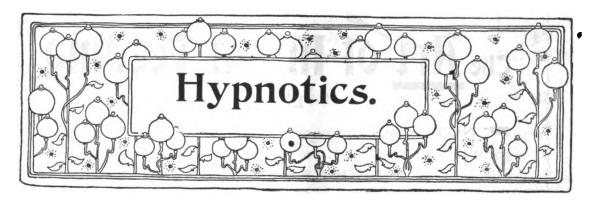

Meacock-Wand.-On April 27th, at St. James's Church, Westbourne Terrace, London, W., Hy. Chas. Meacock, M.R.C.S., L.R.C.P., to Hilda Blanche, youngest daughter of Chas. K. Wand, of Clapham.

SMITH-SEAR.-On April 27th, at the Church of the Sacred Heart, Gibraltar, Peter Colin C. Smith, L.R.C.P. and S.E., L.F.P.S.G., son of Bobert Smith, M.D., of Sedgefield, Durham, to Dorothee de Sales, daughter of the late Iens Bager, Pedersen Skar, of Skar. Norway.

Deaths.

HINNELL.—On April 28th, suddenly, at his residence, Bury St. Edmunds, George John Hinnel, M.R.C.S., L.S.A. HUSSEY.—On April 28rd, at 24 Winchester Road, Oxford, Edward Law Hussey, Esq., F.R.C.S. Eng., aged 83 years.
ORB.—On April 27th, at 204 Earl's Court Road, London, S.W., Andrew Aylmer, M.B.Oxon, eldest son of the late Rev. R. H. Orr, of Stramore, co. Down, aged 40 years.
PRINCE.—On April 22nd, at Crowborough, Sussex, Charles Leeson Prince, M.R.C.S., F.R.A.S., aged 77 years.

Tabloid' BRAND

'Tabloid' Sulphonal, gr. 5 [0.324 gm.].

Readily disintegrates, and is the most convenient and active form in which this valuable hypnotic can be prescribed. Administered in doses of one to six it produces (after three or four hours) sound sleep, which is followed by neither headache, nausea nor vomiting.

Bottles of 25 and 100.

'Tabloid'

Trional, gr. 5 [0.324 gm.].

Resembles Sulphonal in action, but is more prompt. In doses of three to six it induces quiet and refreshing sleep in fifteen to thirty minutes.

Bottles of 25 and 100.

'Tabloid'

Chloral Hydrate,

gr. 5 [0.324 gm.], and gr. 10 [0.648 gm.]

Hypnotic and anodyne. Accurate in dosage, and therefore safe in administration.

Bottles of 100.

'Tabloid' Morphine Preparations.

These products are reliable and safe hypnotics: they keep perfectly, and by their use the dangers of decomposition and loss of strength, common to solutions of morphine salts, are avoided.

TABLOID' MORPHINE SULPHATE, gr. 1/20 [0.0032 gm.], and gr. 1/8 [0.008 gm.].

in bottles of 50.

HYPODERMIC.

TABLOID' MORPHINE BIMECONATE, gr. 1/8 [0.008 gm.], gr. 1/6 [0.011 gm.], gr. 1/4 [0.016 gm.], and gr. 1/3 [0.022 gm.].

'TABLOID' MORPHINE HYDROCHLOR., gr. 1/6[0.011 gm.], and gr. 1/4[0.016 gm.].

Original Communications.

REMOVAL OF KIDNEY FROM FRONT OF SACRUM; RECOVERY.

By EDMUND OWEN, F.R.C.S., Surgeon to St. Mary's Hospital, W.

In connection with the communication by Dr. Newman on Malformations and Displacements of the Kidney, which appeared in the Medical Press and Circular of May 3rd, I would like to place on record a brief account of an extraordinary case of nephrectomy.

On November 13th, 1894, I saw in consultation with Dr. Frampton, a foreign gentleman of an extremely neurotic temperament, who complained of constant abdominal pains. In searching for a possible explanation of this distress, Dr. Frampton, under whose care the patient was, had by digital examination discovered a firm, fixed tumour in the concavity of the sacrum "in front of it there seemed to be a ringlike narrowing of the rectum." "On withdrawing the finger fæces escaped in small, narrow pieces." Two well-known surgeons subsequently examined the case, one of whom gave it as his opinion that the tumour was a simple adenoma which was associated with a slight intussusception of the rectum, whilst the other regarded it as a malignant mass. Having examined the patient under ether, I said that I would not venture even to give a guess as to what the nature of the tumour might be; but that, as the abdominal distress seemed apparently to be caused by its presence, I urged its removal by abdominal section. Two days later, therefore, I opened the abdomen above the pubes, and on dividing the peritoneum as it passed on to the rectum, I introduced my hand into the pelvis and explored the tumour which had been detected through the rectum. Finding it quite free from the rectum, but firmly fixed in its bed, I enucleated it, and bringing it up into the abdominal cavity I tied its pedicle and removed it. Only then could we determine its nature; it was a well-shaped left kidney. (The specimen is now in the museum of the Royal College of Surgeons.)

To say that the patient was neurotic is but feebly to express his temperament. He was a Semitic gentleman who had long sought relief for abdominal pains by morphia, but his craze for sedatives had been somewhat diminished by residence in an institution in America, in which the treatment of the morphia-habit was carried out. A few hours after the operation he became quite hysterical, arched himself upon his head and his heels, and, straining hard, burst open his wound, and forced the intestines out under the dressings. In less than an hour he was again under an anæsthetic, with the bowels replaced, and the abdominal wound restitched. He was a long while recovering, but on February 23rd, 1895, he left the Home in a greatly improved condition, the bowels acting every day with the help of a dose of salad oil.

MALFORMATIONS OF THE KIDNEY AND DISPLACEMENTS WITHOUT MOBILITY, WITH ILLUSTRATIVE CASES AND SPECIMENS.

By DAVID NEWMAN, M.D., F.F.P.S., Surgeon, Royal Infirmary, Glasgow.

(Continued from page 453).

- B. Malformations of the Kidney: I. Variations in number: (1) Supernumerary Kidney; (2) Single Kidney, (a) Congenital absence of one Kidney, (b) Atrophy of one Kidney; II. Variations in form and size: (i) General variations in form, lobulated Kidney; (2) Hypertrophy of one Kidney; (3) Fusion of two Kidneys; (a) Horse-shoe Kidney (b) Sigmoid Kidney, (c) Disc-shaped Kidney.
- B. MALFORMATIONS OF THE KIDNEY: I. Variations in number.
- (1) Supernumerary kidney.—Supernumerary kidney is extremely rare. It must be considered simply as an anatomical curiosity, and consequently very little requires to be said regarding the condition. Although very few instances have been met with where more than two kidneys exist in the human subject, still cases have been recorded by Rayer, and other writers, where a supernumerary gland has existed. We have only seen one instance of this anomaly; it was at a post-mortem examination which was made many years ago upon a gentleman who died from malignant disease of the ascending colon. As no record was kept beyond what was sent at the time to the family-attendant, I am unable to give details: but, from a clear recollection of the case, I can say that lying close to the upper margin of the left kidney there was a small pear-shaped body, supplied by a branch of the renal artery, and having a distinct ureter which passed into the left ureter half an inch below the pelvis of the left kidney. Sections of this mass were examined microscopically, and found to be healthy renal tissue. The mass was completely separated from the kidney proper, being united to it only by the little ureter.

mass was completely separated from the kidney proper, being united to it only by the little ureter.

This anomaly may be regarded as an extreme variety of segmentation of one of the kidneys. Generally when a supernumerary kidney has been seen, it has been found to lie close to a normal kidney, but in order to be placed in this class of malformations, the part ought to be so separated as to possess distinct vessels and have a ureter of its own, which, however, always unites with the ureter of the normal kidney before it reaches the bladder.

normal kidney before it reaches the bladder.
(2) Single kidney.—The anomalies which have been included under this term have been so various and so entirely different, even in their main characteristics, that it is difficult to avoid confusion, and at the same time follow the classification at present adopted.

time follow the classification at present adopted.

The existence of so-called "single kidney" was known by many of the older writers such as Vesalius

Duretus, and Eustachius, but Morgagni, in 1769, was the first writer to classify these abnormalities of the kidney into two groups, namely: those instances in which two organs had become coalesced; and secondly, those where only one kidney had developed; but unfortunately to both of these conditions he applied the term "solitary kidney." Then, following upon Morgagni, Rokitansky limited "solitary kidney" to those cases in which the malformation was due to the fusion of two organs, of which the lowest degree is seen in "horse-shoe kidney," and the highest in those instances in which the two kidneys approach one another more and more, and form one "discounter the state of the state o shaped" organ lying in the median line, and provided with a double ureter. To the other class of kidneys with a double ureter. To the other class of kinneys where there is a "right or left kidney which is normal in regard to position and formation, and occasionally rather enlarged, its fellow being deficient," he applied the term "unsymmetrical kidney." We do not understand why two kidneys fused together as in horse-shoe kidney, where the two organs may be united only by a narrow band (see Fig. 12) and having distinct sets of vessels and ureters, should be spoken of as a "solitary" or "single kidney," any more than that the double monsters Eng and Chang should be considered as one individual. one individual. So much confusion has arisen regarding the use of the terms "unsymmetrical kidney," and "solitary kidney," that it would be well not to employ them. For example, "sigmoid" kidney, a condition where two kidneys are fused together, as shown in Fig. 16, and occupying one side of the body, has been described under the heading "solitary kidney," even although the mass was provided with a double set of vessels and two

Under the term "single kidney" we purpose only to include those cases in which one active organ is found, either as a consequence of atrophy, or from congenital absence of its neighbour. The other abnormalities, such as "horse-shoe kidney," "sigmoid kidney," and "disc shaped kidney," may be considered under the general heading of "fused kidney."

A careful distinction must be drawn between "single kidney" due to congenital defect of development of the opposite organ, and those instances in which a kidney has become wasted and functionally useless as a consequence of disease, while its neighbour has undergone compensatory hypertrophy.

In the former instance no trace of the kidney or of its ureter, or bloodvessels is found, as shown in Fig. 8, while in atrophy of one kidney as a consequence of disease the rudimentary kidney and its vessels are as a rule represented.

The following specimens illustrate (a) congenital absence of one kidney:—

Case 8.—Complete absence of the left kidney, ureter, and vessels. Compensatory hypertrophy of right kidney.

On June 23rd, 1885, we made a post-mortem examination on a patient, Mrs. H., et. 53, who was admitted to the Royal Infirmary under the care of the late Dr. Scott Orr, and died from tuberculous ulceration of the bowels and secondary tuberculous

peritonitis (Fig. 8).

The right kidney was normal in its position, but the whole organ was greatly enlarged, weighing 12½ ounces, and measuring five inches in length and four in breadth. All the parts of the kidney were proportionately normal, and the kidney was supplied by one artery and one vein, both of which were normal in their course and distribution. The right suprarenal body was normal in size and situation, the left suprarenal body was found under the last left rib, and was normal in size and structure. No trace was found of the left kidney or of its vessels and ureter,

and no opening into the bladder could be discovered corresponding to the entrance of the ureter.

MAY 10, 1899.

The microscopic examination of the enlarged kidney was gone into very carefully, and the inquiry was a most interesting one, showing very clearly how compensatory hypertrophy takes place.

The minute changes occurring in compensatory hypertrophy we have described elsewhere. They do not demand attention here, further than to say that as far as could be made out the increase in the size

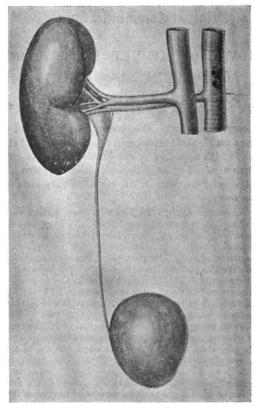

Fig. 8.

of the kidney was due to an augmentation in the bulk of the glomeruli, and to an elongation and increased convolution of the uriniferous tubules, rather than to any numerical hyperplasia.

The changes taking place in compensatory hypertrophy have been carefully studied by Eckardt, Ebstein, Guttmann, Polk, and others.

CASE 9 .- Congenital absence of the left kidney, vessels, and ureter.

The specimen about to be described was placed in the Museum of the Glasgow Royal Infirmary by Dr. J. Lindsay Steven, and in the catalogue is described

by him as follows (a):—
"The preparation shows with the right kidney the bladder and the right ureter. A most careful search at the time of the post-mortem examination failed to find any trace in the body of the left kidney or ureter, the right suprarenal capsule was normal in appearance and situation, and perhaps slightly enlarged, the right renal artery had normal characteristics; the left was scarcely thicker than a stout thread, and was lost in the tissue of the left renal region. The right ureter was quite normal; no left ureter could be found after careful search. patient was a boy, æt. 11, who suffered from morbus coxarius, complicated by tuberculous disease of the

(a) Glasgow Royal Infirmary Museum, Series VII., No. 8A.

The case and specimen described above illustrate single kidney due to the congenital absence of one organ.

The following cases show how (a) one kidney may atrophy or become functionally inactive, either as a consequence of want of growth, or from disease in

CASE 10.—Extreme atrophy of the left kidney with

double pelvis but single ureter. (b)

I have no details of the post-mortem examination in this case. The kidney tissue is almost completely destroyed, and the whole organ is about the size of a walnut. The pelvis is branched, and there is no hilum, the upper limb of the pelvis springs from the inner and upper aspect of the atrophied organ, while the lower limb arises from the lower border of the kidney. Both limbs unite about one and a half inches below the level of the kidney, each branch is of sufficient size to admit the little finger, and after uniting form a channel three-quarters of an inch in diameter. Below this the pelvis gradually narrows and forms a ureter which is a little wider in lumen than normal. In the preparation the vessels have not been

CASE 11.—Atrophied kidney, the renal tissue being almost entirely replaced by fat. (b)

The nations from when the state of the patient from when the state of the

The patient from whom this specimen was removed was under my care in 1887. He suffered for many

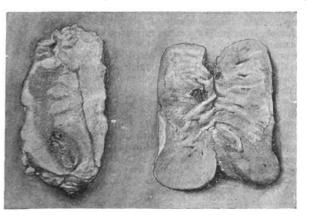

Fig. 10.

years from chronic cystitis, and ultimately died from cardiac disease complicated with passive hyperzemia of the lungs.

At the post-mortem examination the right kidney was found to be in a state of moderately advanced chronic interstitial nephritis, but up to the time of incompetency. The kidney weighed ten ounces. The left kidney, as represented in Fig. 10, weighed half an ounce, very little renal tissue could be found

(a) Glasgow Royal Infirmary Museum, Series VI^r.. No. 9. (b) Glesgow Royal Infirmary Museum, Series VII, No 13.

in the mass, and what remained was completely; embedded in firm fat. In this case the fat appeared to have developed outside the kidney, pushed its way into the interior of the organ by the hilum, and so spread towards the periphery of the organ.

The following specimen was placed in the museum by Dr. J. Lindsay Steven, and he has allowed me to make use of it:

CASE 12—Atrophy of the right kidney with compensatory hypertrophy of the left kidney, disease of the suprarenal capsules.
The following is Dr. Steven's note in the Museum

Catalogue :-

"Both kidneys are preserved, the right only weighed one ounce, the left seven and a half ounces. The organs were obtained from the body of a man suffering from spinal caries. The small right kidney was embedded in a mass of adipose tissue, and at its upper extremity there was a small cavity with smooth walls the size of a hazel nut filled with pultaceous material. The ureter of this kidney was considerably thickened, and its lumen was practically obliterated. The urinary bladder was much hypertrophied. The left suprarenal capsule was enlarged and was converted into a cream-coloured structure, but little tissue of normal appearance remained. suprarenal presented similar appearance." The right

The left kidney was healthy. Fig. 11 shows the atrophied kidney entire and on section, also the healthy kidney.

In the Royal Infirmary Museum there are many other specimens illustrating atrophy of the kidney as

a consequence of disease.

Bright's disease and tuberculous lesions are undoubtedly the most frequent causes of wasting of the kidney, and it is not uncommon in very chronic cases of interstitial nephritis to find both kidneys weigh less than two or two and a half ounces. Such cases are, however, beyond the scope of this paper.

Again, renal atrophy as a consequence of obstruction to the ureter or from endarteritis, cannot be considered at present. It is to cases of congenital atrophy, or wasting of the kidney in early life, that we desire more especially to direct attention, and the cases described above appear to come under this category.

We may now consider some general questions connected with "single kidney" whether due to congenital defect or to complete atrophy of the neighbouring organ. It is of interest to observe that "single kidney" is not peculiar to the human subject, but has been seen in the lower animals also. Sutton, among others, states that this condition occurs in such animals as hens, horses, and sheep, and I have observed it in one instance in a calf. In these animals, as in men, the single kidney has been observed to have undergone increase in bulk. following points in connection with single kidney may beconsidered :-

(a) Duration of life of the individual.

- (b) Size of the kidney, compensatory hypertrophy.(c) Form, position, and side affected.
- (d) Sex and age of the individual
- (e) Liability of a single kidney to disease.
 (f) Condition of the kidney, ureters, and vessels on the affected side, and on the side of the single kidney.
- (g) Malformation of the other organs.
- (h) Position of adrenal body.

 (a) Duration of life of the individual. The absence of one kidney, especially when compensated for by augmentation in size, and by increased functional activity of its neighbour, does not seem to seriously influence the duration of life, so long as there is sufficient renal tissue left in the remaining organ to fulfil the function of life, as doubtless we

17

are endowed, in the normal state, with considerably more renal tissue than is necessary for even active and vigorous life.

In the post-mortem room kidneys containing very little active secreting tissue are frequently found in the bodies of individuals who have, as far as is known, never suffered from any symptoms of renal insufficiency.

The following table shows the age at death of 17 cases of single kidney when death occurred after the age of 60 years was past :-

8	persons	died	between	60-65	year

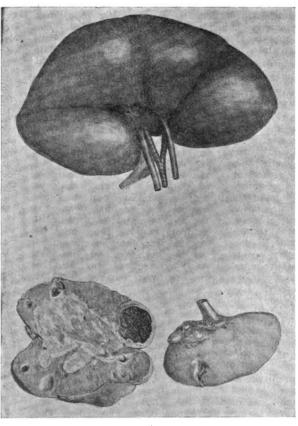

Fig. 11.

It can be easily understood, however, that in an ndividual with only one kidney if that kidney becomes affected by any serious malady such as obstruction to the ureter, thrombosis, or any local inflammatory infection, the risk to life is greatly increased by the existence of only one organ. In single compensatory hypertrophy is the rule when the individual survives through the term of infancy, but even in the feetus considerable enlargement of the kidney has been seen. Morris mentions an instance of this in " a well-informed fœtus born at full time," where "a right kidney only was present, and was twice its natural size; the ureter was much dilated."

(b) In estimating the degree of compensatory hypertrophy in recorded cases, care must be taken to exclude instances where the single kidney has become en'arged by disease; for instance, Morgagni describes a case where one kidney was functionally inactive,

while its neighbour was ten times the normal size, and he mentions another case where a single kidney weighed 35 pounds. Again, Rhodius (a) records a case in which a kidney was so enlarged as to give rise to the suspicion of pregnancy. Eustachius, Vesalius (b), Poupart (c), Perrin (d), Breschet (e), and other old writers have recorded similar cases, in all of which it is very evident that the enlargement was due to disease rather than to a true hypertrophy of the organ. It may be said that when the single kidney is increased to much more than twice the normal size the enlargement is not entirely due to compensatory hypertrophy.

In true compensatory hypertrophy the kidney is found to be homogeneously enlarged in all its parts, and seldom if ever weighs more than two normal kidneys. Take for example other organs. Sometimes hypertrophy occurs in cases of congenital noninflation of one lung, the neighbouring organ being increased in bulk, so also in the liver, when one portion becomes atrophied another may undergo hypertrophy. So many cases of compensatory hypertrophy in single kidney have been recorded that it is impossible to mention more than a few of them. but for the sake of reference I may give the following:—Duckworth (f), Macdonald (g), Palma (h), Brackenburg (i). Northrup (j), Davies (k), Pollock (l), Hewett (m), Gubbin (n).

On the other hand, it does not always follow that because one kidney is undeveloped or functionally useless the other organ must be considerably enlarged. Instances of single kidney, normal in size, have been seen by Turner, (o) Mayor, (p) Hamy, (q) Bostrom, (r) Brown (s) and many others.

(c) Position, form and side affected —In the absence of one kidney the remaining organ may (as in Fig. 8) occupy its normal position in the loin. This is usually the case in atrophy of one kidney from disease. Dr. P. W. Macdonald (t) described a case in which the right kidney and ureter were absent, while the left kidney was normal in position, and had a normal ureter entering the bladder in the ordinary situation. Similar cases have been described by Gubbin, Peacock, Lorain, and Gruber Single kidney, when due to want of development of its neighbour, is more likely to be misplaced and altered in form.

In many cases, however, the single kidney remains normal in shape as well as natural in size, and, even in those cases where there is considerable hypertrophy, the renal for mis strictly maintained, the organ being simply increased in all its dimensions. Indeed, alterations in form are not common. In some cases, however, the organ is much elongated, in others discshaped, angular, or relatively thickened, and not uncommonly lobulated. Dr. M. Watson (u) described a case of congenital absence of one kidney, in which the remaining organ was normal in size but circular

(P)

in form, the surface was distinctly lobulated, and the kidney was situated close to the brim of the pelvis.

Polk (a) also describes a case of single kidney where the organ was displaced into the iliac fossa, while Marzolo (b) records an instance where the right kidney was found lying on the right sacro-iliac synchon-Wiesbach (c) and Lombroso (d) publish drosis. instances in which misplaced kidney was associated with other abnormalities. The side most frequently affected is the left, especially in male subjects; in the female the right and the left kidneys are equally liable to the malformation.

(d) The influence of age and sex. - The abnormality is found twice as often in males as in females, a circumstance which may be accounted for by the fact that necropsies are more often procured in the former sex than in the latter. About 10 per cent. of the specimens published were met with in the body of the fœtus, or in newly-born children, and, in most of these cases, the anomalous condition of the kidney was associated with some other congenital deformity, such as imperforate anus, deformities of the bladder, uterus, ovaries, &c.

In individuals who have lived, notwithstanding the deformity of the kidney, there is nothing remarkable to note regarding their age at the time of death, the mortality being almost equally distributed up to sixty years of age; over that age, as already shown,

seventeen cases are recorded.

(e) Liability to disease in single kidney is marked. Chronic nephritis, renal calculus, tuberculous disease, hydronephrosis, pyonephrosis, and abscess being the most common maladies met with. Morris (e) says: "Probably, as has been above stated, there is a tendency to chronic albuminuria in early or young life in persons with one kidney atrophied. only one kidney exists, and that an "unsymmetrical" organ, there would seem to be a considerable disposition to renal calculus. Of the twelve cases of "un-symmetrical" kidney collected by Mosler, death was due more or less directly to calculus in the pelvis or ureter in nine of them; in the other three, cancer of the bladder and rectum involved the ureter; nephritis, and the consequences of obstruction due to severe congenital phymosis, were respectively the causes of death. In the case of cancer (l'ulpius), a calculus had been passed per rectum in early life, and there was an opening from the ureter into the rectum through which part of the urine escaped."

I have collected eight cases of "single kidney" in which calculus was present. These were published by Rhodius, (f) Jobi, (g) Rokitansky, (h) Rayer, (i) C. Julia Fontenelle, (j) Everard Home, (k) Sylva-

ticus. (l)

Chronic tuberculous and interstitial nephritis is also very common, a few cases of hydronephrosis have been recorded, and one or two of tuberculous disease,

pyonephrosis, and abscess.

(f) The condition of the kidney, ureters, and bloodvessels on the affected side.—In cases of congenital absence of one kidney the ureters and renal vessels on the affected side are absent, or only represented by a cord of fibrous tissue, and in all cases where a rudimentary ureter has been found, the opening into the bladder has been obliterated. Indeed, single kidney due to want of development may be distin-

guished from that caused by disease and atrophy by

the condition of the ureters and the blood-vessels. When "single" kidney is the result of disease the condition of the diseased kidney varies very considerably, it may be represented only by a mass of fibrous tissue, small congeries of cysts, or a nodule of fat. Sometimes the kidney is very small and occasionally lobulated; there may be remnants of renal tissue remaining, and the ureters may be either occluded, patent, or even dilated. The appearance of the wasten kidney depends upon the causes of atrophy, which are either sudden and complete obstruction to the passage of urine from the pelvis, or obliteration of the renal artery at an early period of life. Frequently we meet with greatly wasted kidneys as a consequence of disease late in life, as, for example, in tuberculous lesions, or in chronic inflammatory affections attacking one kidney only. These, however, do not come within the scope of this paper.

The pelvis and ureter of the "single kidney" are seldom much altered, and are never double, as has been described by some authors. Cases of a kidney provided with double pelves, double ureters, extending to and entering the bladder at different points must be looked upon as examples of "fused kidney" rather than of true "single kidney." In many congenital cases, however, the arteries and veins are anomalous in their distribution, and, as might be

expected, are collectively larger in size than normal.

Dr. M. Wilson (a) describes a case of congenital absence of the right kidney where the left organ was enlarged, circular in form, and lobulated on the surface, and situated close to the brim of the pelvis, in front of the common and external iliac arteries of that side, with which it was in contact. which was enlarged at the hilus, so as at first sight to resemble a cyst, gradually narrowed, but continued to be of greater calibre than usual throughout its course, except at the point of entrance into the bladder, where it assumed the normal size. The left renal artery came off from the point of bifurcation of the aorta, passed obliquely downwards and outwards, resting on the front of the left common iliac artery, and entered the upper extremity of the kidney, having previously divided into two branches. Dr. W. F. Menzies (b) describes a case of "single kidney," in which he states that the arterial supply was as follows:

Just above the bifurcation of the aorta a branch was given off from the anterior aspect, and ran to the inferior internal corner of the kidney, entering it at about a quarter of an inch from the edge of the posterior surface. From the right common iliac a third renal artery took its origin, and entered the organ in close proximity, but inferior to the former. The middle and inferior sources of supply were long straight vessels of similar lumen to the superior

Similar anomalies of the circulation in "single kidney" have been noticed by $\operatorname{Hebb}(c)$, $\operatorname{Strube}(d)$ Macdonald Brown (e), Macdonald (f), Duckworth (g)

Tourtual (h).

(g) Malformation of other organs, such as the rectum, the bladder, the uterus, the vagina, and the ovaries, frequently accompany congenital defects in the kidney. This is not to be wondered at when we remember the close embryonic relationship of these parts, but this is a subject which is rather beyond the scope of this paper.

(h) The position of the adrenal body on the affected side varies considerably. Sometimes where the kidney is small or altogether wanting, the adrenal body is natural in size and normal in position; on the other hand, however, commonly the adrenal body is misplaced, and undoubtedly in a few instances may not be present; or again the "single kidney may have two adrenal bodies, as in a case published by Liebmann (a), where a "single kidney," lying in by Liebmann (a), where a "single kidney," lying in the pelvis, had two adrenals associated with it. Brumer (b) states that in forty-eight cases of "single kidney," which he had collected the adrenal bodies were only absent in five.

3. Absence of both kidneys is found in the lower grade of monstrosities only, and, according to Beclard, this anomaly is most frequently met with in acephalous monsters. Chaussier (c) showed a fœtus in which the urinary bladder, kidneys, and uterus were entirely absent, and Mayer (d) also published an example where the same organs were wanting. These cases may be of great interest from the embryological standpoint; and from the physiological side they are also of interest, as illustrating that the most important functions of life may be preserved in utero, without the presence of any renal tissue; but they are of no practical value to the surgeon.

(To be concluded in our next.)

"DAYMARE."

By TOM ROBINSON, M.D., Physician to the Western Skin Hespital.

A GENTLEMAN consulted me with the following somewhat curious history:—"I was coming up to London a fortnight since, and when we were passing through a tunnel a feeling came over me that I must get out. I was trembling, and I felt like a child in a dark cupboard, so strong was this feeling that I left the carriage at the next stoppage, remained all night there, and travelled up to London the following day by a slow train. I am not usually timid in a train, I have never been in a railway accident, and I am totally unable to account for this sensation; all I know is that I feel quite convinced that had I not got out of the carriage I believe that I should have jumped out of the window. I am ashamed to come with such a story. I don't think I am what would be called a coward. As I ride to hounds, and I have been in some tight places in my life, and, honestly, I don't think I ever showed the white feather." My patient was forty years of age; he was, so far as clinical observation went, a sound man. His family history embraced several odd symptoms, without pointing to any definite proclivities either mental or physical. Physically he was a healthy looking man, and conducted himself quietly and sensibly whilst in my room.

It would be easy to select a group of cases which we may designate "Daymare." For instance, it is not uncommon to meet with robust and sturdy men who cannot go near to the edge of a cliff, look out of a high window, or climb a ladder, at least they assert that if they were to do so a strange, trembling, uncertain feeling creeps over them, and they think they must lose their balance and throw themselves Others are unable to sit in a crowded building, such as a church or a theatre. Others, again, will tell us that they experience the same sensation if they are in a crowd. Many women and some men have a sensation of approaching calamity if they ride in a conveyance of any kind which is drawn by a horse. These very individuals will usually ride tranquilly in troubles they usually come under our notice in gathering up the history of a case.

One thing is certain, that the majority of

a train. We are seldom consulted primarily for these

such instances spring out of those who have what is known as the nervous temperament. In other words, they are subject to cold feet, at times pass abundant and pale urine, and have a generally unstable nervous system, with tremulous upper eyelids, best seen when the eyes are shut. There is not any morbid anatomy connected with such cases, the changes are only fugitive and functional. The practical question is, can we suggest any line of treatment with any hope of helping our patient in these odd cases? I am afraid we are only able to point out to these people the fact that the remedy is in their own hands, that they must try to conquer their terror, but we can and we ought to impress upon them not to lean upon alcohol or drugs for support. These will certainly give them confidence for a time, but there is always the force of habit to be remembered, and the man or woman who takes a dose of bromide or opium, or a stiff glass of whiskey, before commencing a journey, runs a risk, and a great risk, of becoming a victim to habit. These patients will sometimes say, "Give me something which I can take when I feel queer, and if we are wise we shall do so. A little tincture of valerian is as good as anything; it will generally remain untasted in the bottle. It is astonishing to notice how many go about with a little bottle full of some medicament which they will be able to take "if they are queer," and it is equally astonishing to know how long a single dose will last confido conquiesco. There are many other terrors which profoundly affect individuals besides these of space, terrors which dislocate the reason and produce physical effects out of all proportion to their origin. There is the large group of individuals who are always going to their doctor because they are afraid they are going mad, others fret themselves tremendously because they are afraid they are going to have some malady such as cancer or consumption. I have known a man labour for some years under the fixed delusion that he was the victim of syphilis; another will gloat day by day over an examination of his own fæces, which, he says, are never healthy. Could any of us define healthy faces? Every internal organ meets the attention of many who have time on their hands and the nervous temperament, and to all these a floating kidney appeals with striking force. And the lives of thousands of women are practically spent in the contemplation of a sluggish liver. In all seriousness such cases are too often the vampires in a family. No one is so selfish as the self-absorbed. Give these patients what names we like, either neurotics, hypochondriacs, or hysterics, say with Shakespeare that "their flesh is mad." the fact remains that to us they look for assistance. With disease which has a morbid anatomy we experience but little difficulty, because we, to a large extent, know the course which the malady will usually run; but these individuals whose whole tissues seem crazy, whose special senses do not appear to see the world as others see it, who, in one word want common sense, these constitute an enormous bulk of those who appeal to us. we can do is to listen patiently to their complaints, to examine every organ carefully, and then to speak with absolute frankness; many of the most gifted men and women which the world has ever seen have had daymare. Martin Luther threw the ink-pot at the devil; Napoleon I. used to say he had heart-disease: Sam Johnson was profoundly imaginative. My late gifted teacher, Dr. Sutton, said with so penetrating a truth, "It really is a grand thing to be nervous. often much unpleasantness and pain are mixed with it, but that is owing to abuse. The world's work is

⁽a) "Centb. fur Chir.," 1887. (b) Virchow's "Archiv.," Vol. LXXII., p. 344. (c) "Bull. de la Faculte de Med. de Paris," 1810, p. 35 (d) "Journal des Progres," Tome IV., p. 281.

done by the nervous. We may see that the greatest workers are the most nervous, the most sensitive among men."

OF **GONORRH**ŒA TREATMENT IN THE MALE. (a)

By J. D. THOMAS, M.D.,

Professor of Genito-Urinary Diseases, Western Pennsylvania College, Pittsburg, &c., &c.

"THERE is no royal road to geometry"; neither is there a royal road to the cure of gonorrhoa, as those who have extensive experience with the disease will testify. That the vast majority of cases of gonorrhea are recovered from within six or eight weeks is true, but it is also true that a certain proportion is very rebellious to treatment. Some of these latter recover after prolonged treatment, whilst a few appear to be incurable. I believe that most urethræ that have once undergone a marked attack of the disease suffer some permanent impairment, evidenced by hyperesthesia, an urethritis of simple character from trivial causes, prostatic neurasthenia, to say nothing of the more gross lesions, such as stricture, &c.; therefore, an early cure is a very important matter, as it prevents the many sequelæ which may follow.

With regard to treatment, I recognise three types, or classes, of the disease, viz.:-1. A virgin gonorrhea, in which the inflammation is of a severe character. 2. A virgin gonorrhea, in which the inflammation is of a moderate or mild character; and 3, a multigonorrhea, for in this last class the inflammation, as a rule, is subacute or moderate. Classes 2 and 3 may be treated along the same lines, unless there are special pathological lesions left from the

previous attacks in Class 3

In the first class, irrigations or injections are impracticable. The urethra is so swollen that the urine is voided in a small stream and with a great deal of pain. It is still more painful to attempt to inject a solution of any kind into such an urethra, for, in the first place, it will not enter, and, in the next place, the attempt is a source of irritation. In this class catharsis is indicated, together with full doses of sodium bicarbonate (or any of the alkalies) with hot water, persistently applied, locally. Quietude, with proper hygiene, general and sexual, is also important. To keep the bowels open, a drachm of sulphate of the evening dose, thirty grains, or more, of bromide of potassium may be combined. This will tend to keep down erections, which are accompanied with chordee, and at the same time aid in securing rest. After the acute symptoms subside, the same line of treatment may be followed in Classes 2 and 3, which I now outline.

Irrigation by the Janet method is, without doubt, a great aid in the treatment of gonorrhea. It is carried out thus: Fill a fountain syringe, placed six to eight feet high, with the solution hereafter described. The end of the rubber tube is fitted with a glass nozzle. The nozzle fits in the meatus, and the irrigation is accomplished without passing any instrument into the urethra. It is not a specific or "sure cure," as some would have us believe, but it is a good method of cleansing the urethra with copious quantities of antiseptic fluids. It is less painful than attempting to accomplish the same results with a catheter or retrojection tube passed to the bulbous portion of the urethra. After the first irrigation, when the patient may be somewhat nervous, the method is painless, agreeable, and satisfactory.

(a) From the "International Medical Magazine," April, 1899.

The best general solution to use is that of permanganate of potassium of the strength of 1-4,000 to 1-3,000. I do not vary the strength of the solution much, for if it is too strong, some smarting will be produced, and it cannot be used in sufficient strength to act as a germicide. Strong solutions are less efficient than those that produce no pain. Having used other solutions, as bichloride of mercury, formaldehyd, &c., and having found them less efficient than the permanganate, I now use the latter almost exclusively.

To make the irrigation method successful, it must be given morning and evening for six days, then once a day untill the case is cured. If at the end of two weeks it is found that no better results are being obtained than by methods that take up less of the physician's time, it is then better to resort to some of

the other methods.

If the patient cannot receive office treatment daily, the Janet method cannot be utilised, except as auxiliary treatment, and it becomes necessary to resort to the injection method. The medicines used for this purpose are numerous. Personally, I prefer the following injection, viz. :-

R Zinci sulphocarb., gr. xv. Acidi boric, gr. xxx. Aq. destillat., 3vj.

Sig.—To be used as an injection every two or three

hours, after urination.

To prescribe an injection to be used three times a day is temporising and inefficient. The patient should also be instructed to use the injection at least twice during sleeping hours. By this method the pus, with the gonococci, is washed away, and nature is given a better chance in the conflict. If the patient is not making satisfactory progress, the physician himself may occasionally give an injection of nitrate of silver, grain ½ to the ounce. In addition to the local treatment, salol with oil of sandal-wood, or

copaiba, may be given three times a day.

When the deep urethra is involved, if we are using the irrigation method, the solution should be carried, after first cleansing the anterior urethra, through the urethra into the bladder; the patient is then permitted to void it. This process is repeated two or three times during each seance, as the bladder will not bear a large amount of the solution at each attempt. When the irrigation method is not practicable, instillations may be substituted, nitrate of silver grain 1 or more to the ounce being used, but not oftener than every three or four days. Salol and the alkalies are here quite beneficial. Hot water, injected into the rectum, may also be useful. If, at the end of six or eight weeks, there remains some discharge, the passage of a fairly full-sized sound may be practiced. If, after the passage of the sound, the case improves, the treatment may be repeated every fourth day, but, if not, it must be discontinued immediately.

Clinical Records.

TWO CASES OF ECLAMPSIA SUCCESSFULLY TREATED BY VENESECTION AND INTRA-VENOUS INFUSION OF SALT SOLUTION. (a)

By Charles N. Cutler, M.D., Chelsea, Mass

THE first case was a primipara, æt. 25, at full term of pregnancy, confined October 13th, 1898; labour normal, duration of second stage about one and one-half hours. The first convulsions came on during the delivery of the head, and were repeated somewhat regularly with fifteen or twenty minutes intervals. The administration of ether was immediately resorted to, and

⁽a) From the "Boston Medical and Surgical Journal," March 30th, 1899.

one-eighth grain pilocarpine with one-half grain morphine given hypodermically. Consciousness did not return after the first interval. Pulse 125, temperature not noted. The patient had five convulsions up to the time of receiving the intravenous injection. Total suppression of urine.

With the assistance of Dr. George C. Hall, the median basilic vein was opened, and about eight ounces of blood allowed to escape, followed by the introduction of about

one quart of normal saline solution.

Ten minutes after completing the operation the pulse fell to 108, later to 104; consciousness returned in half an hour.

The catheter was introduced directly after the injection and two ounces of urine obtained, which became solid when subjected to the heat test. Three hours after the injection twelve ounces of urine were obtained by catheter.

Two hours later, on introducing the catheter, but two or three ounces of urine were obtained, showing a returning suppression; this was very soon followed by a convulsion very much milder in form than those which preceded it. Three convulsions followed at hourly preceded it. Three convulsions romoved intervals. The secretion of urine then began to intervals. crease; fourteen ounces were secreted in the three hours following the last convulsion. Consciousness again returned and the patient recovered rapidly without incident.

Twenty-four hours after the cessation of convulsions the urine showed a slight trace of albumen.

The second case occurred in the practice of Dr. W. G. Bond, of Revere. A multipara with her second child, eight months pregnant, was attacked with a convulsion at 12 a.m., January 24th, 1899.

Premature labour was induced by Dr. Bond and completed about 4 a.m. Prior to this the patient had had three convulsions, notwithstanding the free exhibition of chloral, potassium bromide, morphine, pilocarpine, and the administration of ether.

After delivery the convulsions ceased for eight hours. From 12 o'clock January 24th until 2 o'clock a.m. January 25th she had eleven convulsions, increasing in severity, frequency, and duration, the patient not regaining consciousness in intervals between the last three convulsions.

At 2 a.m. January 25th one-half ounce urine was drawn by catheter, which showed over one per cent. albumen.

At 3 o'clock a.m. January 25th the median basilic vein was opened and from twelve to sixteen ounces of blood allowed to escape, after which the cannula was introduced and two quarts saline solution injected. The pulse rapidly fell from 130 to 88 per minute. Consciousness returned as soon as the patient recovered from the anæsthesia.

The patient was catheterised at 4 o'clock a.m., one hour after the introduction of the solution, and fifteen ounces of urine were drawn; again at 7 o'clock six ounces; at 9 o'clock three ounces, at 12 o'clock twelve

In the twenty-four hours following the operation forty ounces of urine were secured.

At 12.30 o'clock a.m., of the 27th the second suppression of urine began; between this and 3 p m. only nine ounces were secured. At this time, sixty-one hours after the last convulsion, a partial convulsion occurred, followed by delirium, and it was thought best to subject the patient to another infusion. Accordingly the vessel was opened and eight ounces of blood allowed to escape, followed by the introduction of two quarts saline solution. This entirely overcame the delirium. Urinary secretions commenced in earnest, and sixty-four ounces were secreted in the following twenty-four hours, and as much each day until the urine became normal in quantity as well as quality.

Circumstances surrounding the first case rendered it impossible to preserve a more detailed record. Like the second case, it clearly proved the tendency in these cases to a secondary suppression of urine, which must be promptly met by a second intravenous injection. Whether a second bleeding was indicated remains a question of some doubt.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF PATHOLOGY.

MEETING RELD FRIDAY, MARCH 24TH, 1899.

The President of the Academy, Prof. E. H. BENNETT, in the Chair.

BRODIE'S ABSCESS IN TIBIA.

Mr. Henry Gray Croly communicated several cases of Brodie's abscess, and exhibited portions of bone removed by a small trephine and drawings of the cases; the bones were much thickened and diseased. Immediate relief followed the operation in all cases.

Mr. E. H. BENNETT noted that they were not confined to the epiphyses as described by Brodie. He believed that they had nothing to do with tuberculous disease of the bone, owing to their great chronicity, and

the fact that they are relieved by emptying.

Mr. T. Myles related the case of a boy who returned 3 years after operation with a superficial abscess over the site of the original Brodie's abscess. No new bone had formed in the cavity. Another case on which he operated was remarkable in its recovery in that the skin dipped down into the recess, and patient had now a pocket extending backwards an inch in depth into the tibia. He thought that the explanation of the alleged frequency of this condition in the tibia was that the disease was not recognised when occurring in other situations.

Dr. Knorr pointed out that in Brodie's cases there was no external appearance to guide to a diagnosis.

Mr. T. E. GORDON referred to the case of a patient, æt. 45, who had flist noticed a swelling after an injury received twenty or thirty years previously. About twelve years ago a sinus had formed and closed, and a second formed and closed, but a third sinus which formed persisted. A thick layer of dense bone was chiselled through with difficulty, and a large abscess found in the

Mr. CROLY, in reply to Mr. Myles, admitted that circumscribed abscess of bone was not confined to the tibia, though it was met much more frequently there.

ENTERIC PEVER WITH FATAL EMBOLIC HEMIPLEGIA.

Dr. J. W. Moore reported the case of a married woman, set. 29, who died on the forty-third day of an attack of enteric fever. Severe intestinal hæmorrhage occurred as early as the tenth day, persisting for three days. The patient, notwithstanding, progressed favour-ably until the twenty-seventh day, when a fresh rise of temperature, pain in the left side and a choking sensa-tion marked the occurrence of hæmorrhagic infarction in the spleen. Eleven days later, a violent rigor and rapid rise of temperature to 105.6 degs. ushered in an attack of right hemiplegia with complete aphasia. The patient sank and died on the forty-third day. The heart was softened. An ante-mortem clot was found in the left auricle. The left middle cerebral artery was blocked by a firm embolus. The spleen was the seat of several hæmorrhagic infarctions. The terminal few inches of the ileum showed frequent excavations formed by the previous detachment of numerous typhoid ulcers.

Dr. E. J. McWeeney mentioned a case in which the pneumococcus of Fraenkel became localised in the meninges after the morbid process to which it gave rise had been successfully overcome in the lung, also a recent case in which the symptoms were indistinguishable from meningitis, and the real nature of the case was only ascertained by Widal's reaction.

Dr. R. Travers Smith asked if the myocardium exhibited parenchymatous or fatty degeneration?
Dr. J. W. Moore, in reply, said that the endocardium was perfectly healthy, and that he could not account for the ante-mortem clotting. No minute examination of the heart muscle was made.

Dr. D. F. RAMBAUT exhibited specimens of primary carcinoma of liver, with enormous enlargement of spleen.

GALL-STONES WITH MULTIPLE ABSCESS OF LIVER AND CARCINOMA OF THE BLADDER.

The SECRETARY (Prof. McWeeney) showed the liver of a woman, æt. 70, who suffered from severe and persistent jaundice for several months before death, and was thought to have cancer of the liver. Post-mortem the organ was not much enlarged (weighed 60 ozs), but was studded on the surface and throughout with hundreds of small abscesses, varying in size from a pin's head to a hazel nut, and containing a greenish pus, thick and inodorous. The larger bile ducts were greatly dilated and contained inspissated bile mingled with soft gritty concretions. The common bile duct was large enough to hold the little finger, and contained several crumbling calculi, one of which quite blocked the passage into the duodenum. Of gall-bladder there was no trace, its position being occupied by a solid white nodule about the size of a walnut, to which the duodenum was firmly adherent. On microscopic examination this proved to have the structure of adeno-carcinoma, and a gradual transition from normal bile duct to carcinoma structransition from normal bile duct to carcinoma structure could be distinctly traced in the sections. No trace of the wall of the gall-bladder could be detected with the microscope. The hepatic duct ran into this nodule, and the common bile duct ran from it to the duodenum. The cystic duct seemed to be represented by a solid cord about \(\frac{1}{2}\) in. in diam. The abscesses contained two varieties of bacillus coli, both highly virulent for animals. He was inclined to look upon the organisms as the primary ætiological factor, then came the calculi, and finally the conversion

of the gall-bladder into a solid mass of neoplasm.
Dr. LITTLEDALE remarked that in the case of the kidney, when bacterium coli is found in the urine with symptoms of pain about the kidney, it was a sign of

stone in the kidney.

Dr. J. W. Moore commented on the fact that patients recovering from typhoid fever sometimes became subject to gall-stones, probably due to the localisation of Eberth's bacillus producing a deposition of cholesterine and lime salts.

Dr. RAMBAUT, in reply, said that there was a varicose condition of the gastric and esophageal veins, and also the veins behind the peritoneum. He had lately made a post-mortem examination on a woman who died of consumption, and found four abscesses in the liver. From the pus obtained he got almost a pure culture of bacterium

Dr. McWeeney, in reply, said that he had lately seen a very large kidney completely riddled with small abscesses containing a creamy pus which contained one organism only—the bacillus coli in prodigious numbers, and they could be seen easily filling up the urinary tubules. Without doubt, the process had penetrated from the pelvis through the papillæ, along the straight tubules, and had excited suppuration from the interior of the urinary tubules outwards. The same thing is constantly found in what are unjustly called "surgical" kidneys. In cases of typhoid fever, it was his experience to find Eberth's bacillus invariably present in the gall bladder. In fact, the bile seemed to be an ideal medium for the long preservation of the life of various pathogenic species of bacteria.

Dr. NINIAN FALKINER reported a case of peculiar clot from a case of epistaxis.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD MAY 3RD, 1889.

Sir John Batty Tuke, President, in the Chair.

Dr. R. Fleming showed specimens of (1) typhoid ulceration of intestine from a breast-fed child of ten months; (2) gumma of brain; (3) waxy degeneration of kidney and liver.

Drs. Harvey Littlejohn and C. B. Ker read a paper dealing with

THE HISTORY AND CLINICAL FEATURES OF THE RECENT OUTBREAK OF TYPHUS FEVER.

the exact amount of typhus fever in Edinburgh prior to 1879, when compulsory notification was enforced. were, however, many hundreds of case, annually. During the period 1880-98 482 cases were reported, with a mortality of 25 per cent. The yearly average of cases had diminished from 30, with a mortality of 28 per cent. in 1880-9, to 6, with a mortality of 14 per cent. in 1890-7 The epidemic of 1898-9 began in the first week of October, reached its height during November, and died down in the middle of January. In all 82 cases were reported, but there was no doubt that earlier ones escaped recognition owing to the comparative rarity of the disease, and that those which proved fatal were certified as pneumonia, influenza, or bronchitis. The epidemic appeared to have originated at the wake of a man said to have died of pneumonia; it was kept up for two whole days amidst the most insanitary surroundings. Among the lessons taught by this epidemic, the speaker noted that the disease appeared to be communicated by direct contagion only, there being but one case in which this could not be demonstrated. No case was reported where the fever had spread in an infected tenement, apart, that is, from actual personal intercourse. It was also noteworthy that nearly a quarter of the cases occurred in children under ten-three times as many as in the next decade of life. There were no deaths below the age of fifty, and most of the fatal cases were in alcoholic subjects. In one instance, an old woman had infected twenty-two persons—her children and grandchildren—living in different parts of the town. The disease was stamped out by isolation of patients, disinfection of dwellings, and fifteen days' quarantine of all exposed persons. It was found that if some small compensation for rent, &c., were given, no

objections were raised by persons put in quarantine.

Speaking of the clinical features of the epidemic, Dr. KER said that his desire was to learn from some of the older members whether the type of the fever had altered since it was endemic in Edinburgh thirty years ago. ; In two cases where the exact date of exposure to infection was known, the incubation period proved to be thirteen days; in another, the disease developed two days after discharge from quarantine—i.e., at least seventeen days after exposure. Vomiting, headache, and pains in the limbs were the most common features of the invasion, and were present in thirty-seven per cent. of the cases. In a few cases the temperature rose suddenly; usually, however, the rise was gradual, attaining its maximum about the fourth or fifth day. In one patient the temperature actually fell to normal on the morning of the third day—only, however, to rise again. The rash almost invariably appeared on the fourth day, and consisted of three elements: -(1) Raised rose-coloured spots, disappearing on pressure at first, but becoming duller and permanent later; the whole trunk and limbs were covered, but the face was spared; (2) similar spots beneath the skin—the subcuticular mottling—often best seen in the axilla; (3) hæmorrhages. The second of these elements was the first to appear - it might be seen as early as the second day. In all the favourable cases the temperature tended to recede a little about the seventh day, and, as a rule, the cases terminated on the thirteenth or fourteenth day by a crisis lasting for two or three days. Most of the fatal cases died at the crisis—in only one case later. The urine of the fifteen consecutive cases gave the diazo-reaction; after this the examination in this respect was suspended. None of the cases examined give Widal's reaction. One patient had had an undoubted attack of typhus six years previously. Among the complications were two cases of pregnancy—in neither instance did miscarriage ensue. Otorrhœa occurred twice, severe diarrhœa seven times, hypostatic pneumonia six times, parotitis once, and nephritis once. Fewer females died than males; the prognosis was worst in alcoholics, in old people, and in cases whose temperature did not fall a little about the end of the first week. As regards the treatment adopted: the temperature of the wards was kept low, 55 to 60 deg. F. by day, and about 50 deg. F. at night. In addition, few bed-clothes were allowed, and these two Dr. LITTLEJOHN said that there existed no records of procedures seemed to help to keep the temperature down

a little. Insomnia almost always required treatment; for this, sulphonal, paraldehyde, and occasionally chloral, were the drugs most relied upon. It was of some interest that the staff of sixteen nurses and four doctors engaged in looking after the cases escaped completely; Dr. Ker ascribed this to the great care taken to secure good ventilation, and to the frequent sponging of the patients with disinfectants.

Sir John Tuke and Drs. James Carmichael, Affleck, P. A. Young, James, and Argyll Robertson took part in the discussion which followed. It was generally agreed that this outbreak of typhus fever seemed in no way different

from those seen a quarter of a century ago.

HARVEIAN SOCIETY OF LONDON.

CLINICAL EVENING.

MEETING HELD THURSDAY, APRIL 20TH, 1899.

H. E. JULER, F.R.C.S., President, in the Chair.

COXA VARA.

MR. JACKSON CLARKE showed a girl, æt. 3\frac{1}{4}, suffering from unilateral cora vara. The patient when first brought to hospital, walked with a pronounced limp, the body lurching to the left when the foot of that side was placed upon the ground. On examination the left great trochanter was found to be nearly on a level with the anterior superior iliac spine. There was neither eversion nor inversion of the limb, and the head of the femur was felt to move smoothly in the acetabulum. The patient had severe rickets. The treatment adopted in this case consisted in the use of an extension apparatus which was worn continuously. In the earlier stages Mr. Clarke regarded rachitic coxa vara as curable without operation.

CONGENITAL DISLOCATION OF THE HIP.

Mr. Jackson Clabke showed photographs of a girl, set 6, who had congenital dislocation on the left side. The trochanter in this case had been two inches above Nélaton's line, and on manipulating the limb the head of the femur was felt to move about upon the surface of the ilium. Mr. Clarke reduced the dislocation by Lorenz's method under anesthesia It was not until the final movement, that of abduction, was made that the head of the femur was felt and heard to slip into its socket. The thigh was then fixed in the completely abducted and partly everted position by plaster bandages reaching from the iliac crest to the foot. This position was maintained for ten weeks when it was replaced by another with a slightly diminished degree of abduction. The patient now wears a steel instrument and a certain degree of abduction is maintained, and with the limb in this position the head of the femur remains in the acetabulum. The now extensive experience of the results of Lorenz's method of bloodless reduction had proved that congenital hip dislocation up to a certain age was practically a curable affection.

In answer to Mr. Roughton, Mr. CLARKE said he thought some cases of coxa vara were essentially akin to green-stick fractures of the neck of the femur.

ANEURYSM.

Dr. ROBERT MAGUIRE showed a woman who presented the physical signs of an aneurysm involving the arch of the aorta and the innominate artery. Dr. Maguire had seen little good result from prolonged rest in bed and low diet in such cases.

Dr. HARRY CAMPBELL noticed that Dr. Maguire attributed the arterial sclerosis in this patient to syphilis, and asked whether a connection between the two had been definitely established. He thought the patient had granular kidneys, as the heart was hypertrophied, and there was albuminuria. He suggested, by way of treatment, the introduction into the aneurysm, through an insulated trochar, of several feet of fine-drawn gold wire, and the employment of a mild galvanic current, the wire being left in situ. a method which had yielded good results. He did not think that patients with thoracic aneurysm should be doomed to months of enforced rest.

Dr. CAUTLEY expressed surprise at the unfavourable

opinion Dr. Maguire had formed of the treatment by rest and low diet. Although hospital patients are rarely suitable subjects, seeing that the aneurysm is commonly due to a combination of strain, alcohol, and syphilis, he maintained that among the better classes good results can sometimes be obtained by strict Tufnell's treatment. He referred to a very severe case of aneurysm of the transverse part of the arch of the aorta, due to strain, in a gentleman, set 37. After a diet of six ounces of solid food and eight ounces of liquid daily, with absolute rest, for a period of ten weeks, the patient recovered completely, and lived for another 25 years without any recurrence. Similar good results might still be obtained in suitable cases.

The case was also discussed by the President and Mr.

Raymond Johnson and Dr. MAGUIRE replied.

OBLIQUE FRACTURE OF HUMERUS TREATED BY WIRING.

Mr. Roughton showed a man who, in December last, sustained a simple fracture of the humerus, extending from the deltoid insertion obliquely upwards for about 2½ inches. As it was found impossible to keep the fragments in apposition by the use of splints, Mr. Roughton cut down upon the fracture and secured the ends by means of two silver wires passed horizontally round the bone. The patient recovered with a shapely and freely movable arm. The position of the wires and of the fracture after operation was demonstrated by a skiagraph.

EXTENSIVE LUPUS ERYTHEMATOSUS.

Dr. Whitfield ethibited a woman, et. 56, who was the subject of very extensive lupus erythematosus of ten years' duration. The eruption began behind the left ear, and had gradually spread so as to cause a large bald cicatricial patch reaching nearly up to the occipital protuberance. The edges of the patch, where the disease was still active, were red and semewhat infiltrated. On the nose and both cheeks were numerous discoid patches showing very little tendency to involution, and large areas of fine white scarring. Both ears were extensively affected on the inner aspect of the conchæ. The patient presented no evidence of any other organic disease.

In reply to the President, Dr. Whitfield said that the treatment of lupus erythematosus might be divided into palliative and active. In the first class he would include the use of soothing and protective lotions, powders, and ointments. In the second the use of such drugs as pyrogallic acid, chrysarobin, and the oxydised compounds of these drugs, mercurial ointments and plasters, also operative measures, such as scarification and the application of the fine galvano-cautery. He proposed, in this case, later on to use mercurial applications, and if these did not succeed he should try the effect of tattooing the spreading edges with the galvano-cautery as he had seen great benefit from this line of treatment in obstinate cases of the disease. It was necessary to reserve all the active forms of treatment for use when the disease had been reduced to as quiescent a state as possible, otherwise one was liable to do more harm than good.

DISSEMINATED SCLEROSIS.

Dr. James Taylor brought forward a well marked case of disseminated sclerosis occurring in a young girl. In answer to a question by Dr. Harry Campbell it was stated that there was no defect of speech and no emotional excitability. The patient was gradually getting worse, and it was feared that the prognosis was hopelessly bad.

PARALYSIS OF TRAPEZIUS MUSCLE.

Dr. Harry Campbell showed a case of complete paralysis and atrophy of the scapular portion of the right trapezius, apparently due to the involvement of the spinal accessory nerve in an old cicatrix. The case showed the important part taken by this muscle in keeping the scapula in position. The bone was considerably altered in position, the glenoid cavity looking downwards and outwards, and the inferior angle projecting as in 'winged' scapula; the outer part of the clavicle was bent downwards by the fall of the acromion and coracoid process. The patient showed an occasional

tendency to a form of wry-neck from over action of the opposite trapezius.

In answer to Dr. Jaffe, Dr. CAMPBELL stated that the lower part of the muscle showed the reaction of degeneration.

TREATMENT OF LOCOMOTOR ATAXY BY EXERCISES.

Dr. LEONARD GUTHRIE demonstrated upon a case of locomotor ataxy, the treatment of the disease by specially arranged exercises, as suggested by Frenkel. The power of co-ordination had been considerably improved.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MAY 5TH, 1899.

The President, Dr. S. D. CLIPPINGDALE, in the Chair.

Dr. Charles Charman showed specimens of (1) Adherent pericardium in a child; (2) Calcifaction of the aortic valves.

Mr. H. J. PATERSON read a paper on the

USE OF GAS IN GENERAL AND DENTAL SURGERY.

After explaining that his object was to plead for a more extended use of nitrous oxide anæsthesia, he pointed out that although using the single word "gas," he implied thereby that it was given with a suitable proportion of air or oxygen. The advantages of gas were its safety, pleasantness, and freedom from causing after effects. He contended that it was safe, provided that asphyxial symptoms were avoided to prolong nitrous oxide anæsthesia for one or more hours, and recorded a case in which anæsthesia was maintained by means of gas and oxygen for two hours and ten minutes. There was no evidence that prolonged administrations affected the heart injuriously, provided that asphyxia was guarded against, and any effect on the heart was due to neglect of this precaution. In giving gas the danger signs were readily observed and gradually developed; hence he had come to the conclusion clinically that for operations long or short nitrous oxide gas mixed with air, or better with pure oxygen, was the safest anæsthetic we possess. The danger of passing from gas anothesia to chloroform was pointed out. He expressed the opinion that there are few operations which cannot be performed under gas if desired, and many in which this anæsthetic is preferable to ether or chloroform. Its use in collictomy was at present inadmissible on account of the difficulty of ensuring freedom from occasional retching movements. He strongly deprecated its use during the removal of adenoids. Mr. Paterson next dealt with the question of prolonged nitrous oxide anesthesis in dental prac-He showed his new design for apparatus for tice. He showed his new design for apparatus for administering gas through the nose, and contended that this was the best way of administering gas in all dental cases. He proceeded to ansethetise two female patients by this method, while Mr. Lloyd Williams performed prolonged painful operations on the teeth. The demonstration was a brilliant success. In the discussion which followed, Mr. Swinford Edwards, Drs. G. D. Robinson, Charles Chapman, Mark Starling, Richard Lloyd, Lloyd-Williams, McAdam Eccles, Bellamy Gardner, and Keetley took part.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD IN MANCHESTER, APRIL 21st, 1899.

Dr. Donald, President, in the Chair.

SPECIMENS.

DR. W. E. FOTHERGILL: 1. Umbilical cord with knots, child being born alive. 2. Two months' feetus, with well-marked umbilical vesicle.

Dr. Lea: A fectus, with sections and photographs.
Dr. S. Buckley: Blood cyst in connection with
Fallopian tube, removed by abdominal section.

Dr. J. S. MARTIN: Two ovarian cysts, with hæmorrhagic contents.

Dr. LLOYD-ROBERTS: Tubal gestation, with intra-peritoneal rupture, removed by abdominal section. Dr. W. WALTER: Uterus with multiple fibroids re-

moved by total abdominal hysterectomy.

Dr. W. K. Walls described the labour in the case of a woman who possessed a "uterus bicornis." The right horn, containing the placenta, was strongly retroflexed into Douglas pouch; the os uteri was found to be high up behind the pubes, and a hand presented. Delivery was effected by version under chloroform, and after replacement of the right uterine cornu. During the lying-in period the left horn became retroflexed, and caused much discomfort from piles. All the symptoms were immediately relieved by replacing it.

Remarks were made by Drs. Sinclair, Briggs, and the

President, and Dr. Walls replied.

Dr. Sinclair read a short paper on

MALIGNANT ADENOMA OF THE BODY OF THE UTERUS,

illustrating his remarks by specimens and microscopic sections from four cases. He also made incidental reference to two cases of malignant adenoma of the cervix, from which microscopic sections were also shown. He mentioned several anatomical and clinical features of this form of malignant disease, which seemed to differentiate it from carcinoma. Anatomically it is not distinguishable by the microscope from the rough form of adenoma, although there is a form of adenoma which from microscopic appearances may be confidently declared malignant. In support of this opinion sections were shown from a case which had been observed through the stages considered benign until extirpation of the uterus had to be resorted to for a clearly malignant condition. Sections of the body in this case showed invasion of the muscle by the adenomatous growth. Clinically, the chief point dwelt upon was the more chronic course of malignant adenoma as compared with carcinoma. Some minor clinical differences were also said to exist.

Remarks were made by Dr. Briggs, Dr. Fothergill, Dr. Lloyd Roberts, and the President. Dr. SINCLAIR

replied.

France.

[FROM OUR OWN CORRESPONDENT.]

APPENDICITIS.

Paris, May 7, 1899.

At the last meeting of the Société de Chirurgie M. Poirier said that, after the long discussions on appendicitis which had taken place at previous meetings, it would be interesting to note the conclusions at which they had arrived. The cases he had observed led him to affirm that every case of acute appendicitis should be operated upon as early as possible. This opinion appeared too absolute at first, and provoked numerous protestations.

M. Brun said that a distinction should be made between cases of septic appendicitis where urgency imposed itself, and those where the symptoms allowed the adjournment of the operation to a more favourable moment. One of his colleagues (M. Routier) insisted, however, and very rightly, on the extreme difficulty of making that distinction at the outset of the affection, and added that if he had sometimes regretted to have abstained from operating, he never, on the other hand, had to repent of having interfered. M. Broca advised temporising for all cases where neither general peritonitis nor a purulent collection were present. M. Jalaquier, while admitting that the resection of the appendix was indicated when the operation could be performed

on the first symptoms, declared that in general it would | be well to wait until the acute phenomena had subsided in order to insure success. MM. Walther and Schwartz were of the same opinion, but M. Lejars believed that delay was dangerous. On the other hand, M. Guinard qualified the assertion of the speaker as contrary to the interests of the patient, and maintained that intervention in the acute stage was only admissible where the existence of pus was clearly diagnosed. M. Quénu recently declared that he was always disposed to operate in every acute appendicitis. MM. Tuffier, Nimier, Chaput, Pozzi, Berger, Segond, Michaux, Hartmann Picque and Peyrol were all of the same opinion as the speaker; consequently there was a large majority for early interference. Even in cases where the diagnosis was not very clear it was preferable to operate rather than temporise. The operation should be as complete as possible, that was to say, that in all cases the appendix should be sought for and removed.

INJECTIONS OF COCAINE INTO THE MEDULLA.

Professor Bier has made some interesting periments on the anesthetic effects of cocaine injected into the spinal cord. Up to the present two methods only were known of producing anesthesia. that of inhalation of chloroform, ether, &c., producing general insensibility, and local anesthesia obtained by the action of cocaine or cold on the sensitive nerves of a limited region. Prof. Bier has discovered a third or middle method by which two-thirds of the body can be rendered insensible, and leaving psychic faculties untouched. Convinced that the injection of a small quantity of cocaine into the rachidian canal would produce insensibility of the regions tributary to the nerves contained in that cavity, he injected hydrochlorate of cocaine into the rachidian canal of six patients with ages ranging from eleven to thirty-four years, and was able after this operation to perform without the slightest pain, osseous resections and the opening of tuberculous abscesses. He proceeded as follows:-By means of subcutaneous injections of cocaine he rendered insensible the lumbar region, and then practised the tapping of the canal according to the method of Quincke with the aid of a very fine canula; to this he adapted an ordinary Pravaz syringe, containing from one-half to a one per cent. solution of cocaine, and of which he injected from ten to sixty drops, representing from one-tenth to one-third of a grain. In five or eight minutes after the injection the lower limbs were rendred completely insensible, and the anesthesia crept up the body as far as the sternum. The effect lasted forty-five minutes, and then gradually disappeared. None of the patients presented any uneasy symptoms, but three of them, however, suffered from vomiting and headache for a few days. All of them looked on, while being operated on, with complete sang froid, asserting that they felt no pain.

MEDICAL STUDENTS-FRENCH AND FOREIGN.

According to the latest statistics there are, in the Paris Faculty of Medicine, 3,866 students, of which 486 are foreign, while in the different schools of the provinces they number 4,403, of which 345 are foreigners. Consequently the total for the present year is 8,269 or 47 less than last year, and 647 less than the year 1895. The largest decrease is to be found among the foreign students. Of the nationality of these latter, 34 are by the production of circular and radial fissures.

from Germany, 16 from Africa, 18 from South America, 147 from Bulgaria, 34 from Greece, 15 from England, 76 from Roumania, 226 from Russia, 22 from Switzerland, 131 from Turkey, &c.

Germanv.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 5th, 1899.

THE SURGICAL SOCIETY.

HR. LIBMANN, Greifswald, read a paper on FRACTURES OF THE SKULL.

In lesions of the brain he said we must distinguish between the uninjured and the injured skull. Whilst in the latter group the destruction of the brain mass was greater, in the first the injury was generally the so-called concussion of the brain which might be fatal, the theory of which was not explained. The view was extensively held that capillary apoplexies were the cause, but this did not agree with the clinical symptoms, and in experiments on animals on presentation of similar symptoms, these apoplexies were not found. Then a general lesion of the brain had been assumed to be a molecular displacement, whereby the absence of apoplexies and the often surprisingly rapid disappearance of symptoms had been explained.

In order to form some definite idea, the speaker had carried out a number of experiments in imitation of force within the interior of the skull, 1, in falls from a he ght, 2, in blows on the head when this rested on a firm base; 3, when it was freely movable. had an iron box made, and filled with starch paste, in the middle of which, a metallic ball was placed, and then the box was hermetically sealed. If the box was now dropped from a great height it would be found that the ball had moved towards the spot struck in the fall, but if it were struck while resting on a firm ground, the ball did not move, again, if struck whilst freely moving, the ball moved towards the spot on which the blow was struck. These appearances depended on the known physical law of inertia. When we have to determine the effect of a fall on the contents of the skull, we have to bear in mind the varying consistencies of the contents. The white substance has the greatest density, then the grey substance then the blood, and lastly the cerebro-spinal fluid. If a man fell on his skull from a great height, the blood would be forced towards the capillaries, but would not rupture them without great force. The white substance would be propelled further than the grey, and a want of correspondence would arise between them. Hæmorrhage would take place mostly in the grey substance, because it was very vascular, and because it had a less firm consistence than the white.

The speaker then made experiments in reference to the occurrence of fracture of the skull. For the purpose, he took glass balls, which he filled with gelatine, one completely and one incompletely. On letting them fall on the floor, the fall caused large cross fissures in the one, whereas in the other there were only radial fissures, starting from the point struck in the fall. A skull filled with lead wire, on being struck, showed only local injuries, unless the blow was very powerful. A skull filled with gelatine and hermetically closed, was broken into pieces

Herr Gussenbauer mentioned, in connection with Kocher's address, that in his experience many cases supported his (Kocher's) theory, where others did not. In cortical epilepsy excision of the cicatrix had not unfrequently been useful. Also in osteoplastic operation on the skull, followed by firm healing of the bone, the epilepsy was sometimes permanently cured.

In regard to Libmann's paper, the speaker had omitted one factor that had to be reckoned with, viz., that the blood and cerebro-spinal fluid were not under equal pressures, moreover, the pressure in the arteries differed from that in the veins. The cerebro-spinal fluid, under changed conditions of pressure, did all the mischief.

Herr Libmann, in reply, said that the cerebro-spinal fluid forms a pad which afforded protection for the other contents of the skull.

Dr. Friedriech, Leipsic, read a paper on

AIR-CARRIED GERMS AND BACTERIAL ABSORPTION. and concluded from a number of experiments that infection during an operation might be considered as excluded, and further that for infection to take place a certain amount of pressure was necessary, as when the tail of a mouse was cut off and anthrax germs were lightly applied, no infection took place, whilst if some pressure were applied over the wound, the animals died within thirty or forty hours.

Hr. Sänger, Crefeld and Schlosser, Prague, read papers on the well-worn subject of infective sterility of the hands and gloves for operations.

Hr. Schnitzler, Vienna, discussed.

LATENT ORGANISMS

with a view of ascertaining whether organisms could remain latent in the system for any length of time, and later on take an active stage. Animals that were refractory to certain organisms were inoculated with them, and months afterwards a second morbid substance was introduced. The virulence of the material first injected at once showed itself. Frogs were inocculated with the staphylococcus. These remained local, and caused no general infection. If ever frogs were narcotised however, they died, and staphylococci were found in all the organs, the chloroform had lowered the resisting power of the organism. It followed from this that frequently for a micro-organism to become active there must be a disposition, a lowered vitality, for example, through a chill. This explains late suppuration in cases of foreign bodies.

Hr. Hoffa, Wurzburg, related a case of

HABITUAL LUXATION OF THE KNEE-CAP. The patient was a girl who some years ago experienced a sudden pain in the knee and fell down. Since that time the condition had become worse, and the girl came to the hospital. As soon as she went a few steps, the patella became displaced, she had violent pain in the knee, and fell down. Various kinds of bandages were tried, without avail. Le Dentu had proposed the following operation in such cases: A transverse fold was to be formed in the capsule of the joint, stitched into the form of a roll, whereby the capsule was shortened. The speaker operated in his case in that way, and got an excellent result. The patella remain firm, and a previous atrophy of the quadriceps had quickly improved.

Hr. Krönlein related a case of

TRAUMATIC ULCER OF THE STOMACH, and showed a preparation from a man, aged 48, who had

circular resection of the pylorus performed in November last, for stenosis of it. He was a healthy man who, in June last, was struck with a hay-fork in the neighbourhood of the stomach. He felt violent pain at the time, but this disappeared, so that in two or three days he was ready for work again. Then he lost his appetite, and lost flesh; the pains returned, and three weeks after receipt of the injury frequent vomiting took place, but with no blood; finally all food was rejected, and symptoms of closure of the pylorus became pronounced. The operation was performed, and the patient had gained 8 lbs. in weight. The ulcer was very large, of circular form, and implicated the whole pylorus, the ulceration passing down into the sub-mucosa. Carcinoma could be excluded by the microscope. The case was interesting from the point of view of accident insurance, for there could be no doubt that the injury led to the ulceration.

Hr. Wagner Konighütte related a similar case. A young healthy man had a contusion of the abdomen five years before, and a day or two after, copious bleeding took place, and since then hemorrhage had taken place from the stomach at intervals.

VIENNA, May 6th, 1899.

BILE COLOURING MATTER IN URINE.

Ar the "Medical Club" Dr. Jolles read a long paper on the various tests in use for the detection of bile in urine and its quantitative estimation. He referred to a paper on the same subject which he had published in 1894 to show the inaccuracy of Huppert's test which had been brought forward at that time to supersede all others. In practice it was found to be misleading, as a large quantity of the bilirubin escaped detection.

J. Munk had recently introduced a novel method which is an advance on the former, yet a large quantity of the bilirubin passes undetected according to Jolles' proofs.

Jolles' own method, which is the most perfect extant, may be briefly stated:-10 cc. of the suspected urine is placed in a test tube to which is added 1 cc. of chloroform, 5 cc. of a ten per cent. solution of chloride of barium, well shaken, and then allowed to stand for a few minutes. The clear supernatant fluid is then syphoned off, and the sediment treated with two or three cc. of Hubb's $\frac{N}{100}$ iodine solution and 1 cc. of concentrated

hydrochloric acid. The test tube is well shaken and again allowed to stand. If the slightest trace of bile be present the later sediment will have a bluish-green colour. The chloroform solution will assume the bluish. green colour also if the iodine solution be applied to it.

The iodine solution is made by dissolving 0.13 gramme of iodine and 0.16 gramme of mercuric chloride in 100 cc. of alcohol (90 per cent.). For practical purposes Jolles proposes the combination of these two solutions as a ready qualitative test for bile.

Jolles' quantitative test is based on the fact that bilirubin in urine, when treated with an alcoholic-iodine solution, produces a green colour, which must be in the proportion of one molecule of bilirubin (C₁₆ H₁₈ N₂ O₃) to two atoms of iodine. The method is completed by trituration.

OPERATIVE MYOPIA.

Fukala showed two cases on which he had operated for

myopia; the one was -33D, the other -11D, and both become emmetropic after removal of the lens. According to the -18 dioptric dictum the removal of the lens in the -11D eye should have converted it into a hypermetropic one which, strange to say, was not the case as demonstrated in the patient exhibited.

Elschnig asked Fukala how he determined the myopia before the operation, as the results surprised him. The only explanation of this strange phenomenon which he could suggest would be in the altered radius of the cornea. His own opinion was that no operation of this sort should be undertaken with less than -14 dioptres, but -11D was certainly a surprise.

Fukala replied that the one with —11D was determined by Schnabel, while the other was worked out by Sattler. He confirmed it himself by a 10 mm. from the convexity of the cornea.

Schnabel said that he was familiar with both of the cases, and must confess himself surprised at the result, as he expected to have to apply +7D or +8D to neutralise the hypermetropia after the operation. There were exceptional conditions in this case that ought not to be lost sight of before establishing any rule. The eye, although requiring -11D to correct it, had an axial length of 30 mm., which would favour such an operation.

Fukala replied that the presence of unusual circumstances induced him to perform the operation, as the patient, from the nature of his work, found the myopia a great burden to himself, and he therefore determined to convert it into a hypermetropic eye, which would be more suitable for the patient's duty. He thought the explanation of this phenomenon might be found in the changes of the long axis of the eye after the removal of the lens. Schnabel thought Fukala's explanation was not sufficient, as a myopia of — 11D could only become emmetropic after the removal of the lens if the lens had a very high refractive power.

This condition could not be accurately diagnosed in the living eye, and was therefore impracticable in practice. He was of opinion that no useful result could be obtained by following this unusually fortunate example.

Elschnig described Fukala's hypothesis as fanciful, and absolutely without scientific support.

The Operating Theatres.

ST. MARY'S HOSPITAL.

PRIMARY AMPUTATION OF THIGH FOR INJURY .- Ex-TREME SHOCK. INTRA-VENOUS SALINE AND BRANDY INJEC-TIONS.-Mr. QUARRY SILCOCK operated on a lad, æt. 16, who had been run over by a cart, the wheel passing over his right thigh. On admission he was extremely collapsed; stimulants were given, and his condition slightly improved. An examination revealed a compound comminuted fracture of the middle of the femur and very extensive laceration of the muscles at the back of the thigh and calf, exposing the bones. Owing to his collapsed condition immediate operation was thought inadmissible, and restorative measures (rectal injections of saline and brandy) were employed. On being seen again by Mr. Silcock the temporary dressings were found to be soaked with blood owing to the cozing; therefore the boy was taken to the theatre, his general state being, however, but little improved. An amputation was done in the upper third of the thigh, and it was found necessary to

utilise the skin which had been stripped from the fascia lata at the time of the accident to fashion flaps in the hope that it might survive. The superficial and deep femoral vessels were ligatured in one mass close to their bifurcation. During the operation three pints of sterilised physiological saline solution, containing two ounces of brandy, were slowly transfused into the left median basilic vein. The amputation was done as rapidly as possible; a very small quantity of blood being lost, the elastic tourniquet proving very effective.

Mr. Silcock said that primary amputation of limbs for injury were becoming excessively rare owing to the successful conservatism of modern surgery. In the case upon which he had just operated amputation was rendered necessary, although the femoral vessels were intact, owing to the extensive laceration of the muscles on the whole extent of the back of the thigh, and the tearing away of the skin over the whole area of the lower three-fourths of the thigh, together with the comminution of the bone, and also owing to the fact that the damaged tissues were ingrained with dirt and filth, which it would have been impossible to remove. He pointed out that when the lad was first seen at the hospital he seemed to be actually moribund, and immediate amputation was out of the question; therefore he determined to see him again in a few hours, hoping his condition When seen, however, in about would be improved. three hours, these hopes had not been realised. no improvement having taken place, but the oozing which was now evident through the dressings made interference absolutely necessary. Mr. Silcock said he had utilised the damaged skin, as there was insufficient covering for the stump, even if the limb had been removed at the hip-joint. The femur, however, was sawn through just above the junction of the upper and middle third. He pointed out that the effect of the saline and brandy injection was extremely marked; the radial pulse, which at the beginning of the operation was imperceptible, was nearly at once readily appreciable. How far the admixture of the brandy with the saline was responsible for these good effects he was unable to say, as he had had no previous experience of the intra-venous injections of alcohol, but he had been induced to try the method in this case owing to the apparent hopelessness of the patient's condition. He was however inclined to think that the alcohol played a comparatively small part in the restorative effect, because stimulants had been tried very freely before the operation, though certainly not by intra-venous injection. He did not suppose that anyone would go so far as to say that the same amount of alcohol injected intra-venously by itself would have been of great avail (of course, in any case it could not be employed except in a state of very considerable dilution). He remarked that at a future time the condition of the stump would have to be dealt with in order to get rid of the probable conicity which would obtain if it became largely uncovered owing to the loss which he feared would take place in the flaps by sloughing, a condition which, though foreseen at the time of operation could evidently not be avoided.

For the following account of the subsequent progress of the case, we are indebted to the courtesy of Dr S. Maynard Smith.

The patient recovered fairly well from the anæsthetic, and his condition slowly improved throughout that night and the following day. At 3 a.m. on the morning of the next

day he suddenly became worse, and showed symptoms of severe collapse. The radial pulse was absent from the wrist. A second transfusion of two and a half pints of saline solution, containing two ounces of brandy, was made into the right median basilic vein. There was an instant improvement which was well maintained, and rapid progress has since been made to convalescence. Parts of the flaps formed of the damaged tissues became gangrenous, and were, therefore, removed, but at present the patient is convalescent, and healthy granulations cover spots whence the gangrenous patches were removed. The effects of the second injection of saline and alcohol were, therefore, as excellent as those of the first, and evidently more lasting, as they formed the starting point of the patient's convalescence.

REGISTERED FOR TRANSMISSION ABBOAD.

The Medical Press and Circular. Published every Wednesday morning, Price 5d. Post free, 5dd. ADVERTISEMENTS.

FOR a Series of Insertions:—Whole Page, thirteen insertions (weekly, fortnightly, or monthly), at £3 10s. 6d.: twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.: fifty-two insertions (weekly) at £3 each. WEDNESDAY, MAY 10, 1899.

THE PRINCE OF WALES' FUND AND THE SMALL HOSPITALS.

THE Royal Fund for the London hospitals is based upon principles so generous and so humane that the average man is tempted altogether to suspend his critical faculty. At the same time it will hardly be denied that a young institution is likely to possess some at least of the follies and imperfections of youth. The methods of raising money by philatelic devices, for instance, and by the granting of orders, savour rather of the ways of the charitable bazaar than of a royal appeal on behalf of a splendidly humane object. But it is with the distribution of the Jubilee Fund we are concerned rather than with its peculiar views upon eleemosynary ethics. First and foremost comes the question of the small hospitals and their share or otherwise in the awards. The lesser institutions stand in a sort of no man's land, and we note on the General Council of the Prince of Wales's Fund the names of well- of hospital abuse, but we venture to ask if the Royal

known philanthropists who have openly advocated the extinction of the smaller hospitals. particular views have been enforced by the Metropolitan Hospital Sunday Fund, but we are glad to say that the Saturday Fund has taken a juster view of the matter, and has made awards freely to the medical charities, great and small. As regards this point we long ago pointed out that one of the Funds must be right and the other wrong, but so far as we can remember no satisfactory explanation has ever been given by the Sunday Fund, of the principles upon which they have refused awards to most of the institutions. We exposed long since the fallacy of insisting upon a fixed relation between maintenance and to impose such a condition is to foster extravagance of the wildest kind in hospital administration. At the same time the Sunday Fund has again and again granted solid sums to institutions that laboured under grave unanswered public charges of dishonest management. while it refused any help to other medical charities administered with prudence and economy to the last penny. Are we to assume that the Prince's Fund will adopt the policy of swamping the small hospitals? The answer to this question will be found in the list of awards, and meanwhile we should feel greater faith in the actions of the Council if fewer of its members were not already committed in that direction. The offer of a Visiting Committee to visit each hospital applying for a grant is a comparatively slight safeguard if the minds of the Council are made up beforehand. Certainly, the greater number, if not all, of the smaller hospitals that have altered their methods of accounts in compliance with the conditions imposed by the Sunday Fund, and who have applied for a grant with clean hands, have come empty away. Is the same thing to happen in the case of the Prince of Wales' Fund? It seems that if the smaller Institutions are to be thus tabooed, the better plan will be to transfer their allegiance to the Saturday Fund, which is the only great central distributing agency in the metropolis which has treated them with common fairness. With the smaller charitable Institutions, as with other social organisations, unity is strength. Then there is another point on which we want some sort of definite assurances from the Prince of Wales' Fund, namely, as to their attitude upon the great question of hospital reform. At least four of the large hospitals make a money charge to patients, a fact that affords a curious commentary upon the ways of those responsible for the administration of vast charities. Is the fact of a money payment being exacted from patients taken into account by the Prince of Wales' Fund? Then there is the further point of wards for paying patients which are founded by several of the great hospitals, such as Guy's and St. Thomas's, upon funds subscribed for the relief of the poor, if carried on to the injury of the main mass of the medical profession. There are many other matters involved in this knotty question

Fund takes into consideration the fact that any particular hospital does or does not institute systematic inquiry with a view of excluding improper persons from participating in funds of the charity. The constitution of the General Council of the Royal Fund is not above criticism. Among the really active members may be noted many who are committed to the support of the pay system by hospital patients, and of other abuses of which the general practitioner has complained bitterly for many a year. The Council is not representative of any but a narrow section of philanthropists. The main mass of the medical profession and the smaller hospitals are unrepresented. With a little more attention to these points we venture to say that the Prince of Wales would be more likely to convert the medical profession as a whole into active supporters from their present position of luke-warm critics.

A HOSPITAL SCANDAL.

THE affairs of the Liverpool Hospital for Cancer and Skin Diseases appear to have fallen to a very low level if the literature emanating from its officers can be accepted as any measure of their morality. It seems that there are three honorary medical officers on the staff, Drs. Crawford, Taylor, and Whitford, and their relationship appears to have recently become strained, although some of the present charges date as far back as 1883. Notwithstanding these irregularities apparent harmony reigned until about two or three years ago when ominous clouds began to gather around the institution. They culminated in open charges of immorality, &c., against the senior Medical Officer, Dr. Crawford, which could only be met by a thorough investigation into the serious accusations brought forward by his two colleagues Drs. Taylor and Whitford. On October 13th, 1898, the General Committee of the hospital selected five of their number to investigate the charges and report to the General Committee. This would have been an excellent opportunity for clearing up such an obnoxious scandal had the General Committee at this time acted prudently. In the selection of this Sub-Committee, however, three friends of the accused officer were chosen, to whom the accusers took exception on their appointment and in the presence of the Sub-Committee. The chairman's notice was forcibly directed to the fact, but he, poor man, could not see anything "wrong or inexpedient in Mr. Millar acting on the Sub-Committee," although Mr. Millar happened to be Dr. Crawford's private solicitor and patient. We are told in the Sub-Committee's report of March 8th, 1899, that their labours were preceded by an invitation to the Medical Officers to propose suggestions as to improvements in the internal management of the hospital." Now comes the dénouement. Whitford accuses Crawford (1) of using the hospital for personal gain; (2) of ignoring the regulations as to fees; (3) of having retained the services of hospital nurses for his private purposes; and (4) that impropriety had existed between Craw-

ford, the matron, and the wards maid, &c. Crawford retaliates by accusing Whitford of visiting the matron at improper hours. Finally, the Sub-Committee concludes with recommendations for the better government of the hospital, finding that the charges brought against Crawford by Whitford and Taylor had "no foundation," and that there was no harm in the matron being kissed "without her consent." Indeed, they "could not understand a lady of Miss Thompson's character remaining on friendly terms with a man who had been guilty of improper conduct, while they considered her indiscreet in permitting Dr. Whitford's visits to be so frequent at such late hours." This report was signed by the five members, one of whom has since withdrawn from the position, and presented to the General Committee on March 23rd, and adopted with two dissentient votes, Drs. Taylor and Whitford. On April 10th the General Committee again met with a number of disapprovals, calling on Drs. Whitford and Taylor to resign, as well as the matron. A requisition was then sent to the Liverpool Medical Institute calling a meeting for April 29th, to consider the anomalous position of affairs which resulted in that body refusing to have anything to do with such questionable matters. The latest to hand is that a general meeting of the donors, subscribers, &c, of hospitals is called to meet on the 10th inst. (to-day) to decide what future steps are to be taken to restore order. We wish them God-speed, and we trust that the steps decided upon will have the desired effect. We have studiously avoided any unnecessary personal details, even though some of them appear to be distinctly germane to the matters under considera-We are, however, less concerned with the morality of individuals than with the good management of a medical charity.

THE CARE OF EPILEPTICS.

It is remarkable that such a deserving class of hapless persons as chronic epileptics should not have excited more sympathy in this country than the past has proved to be the case. This fact has attracted a good deal of notice among our Continental neighbours, especially in view of the solicitude which we have ever displayed for our insane. This country set the example to the world in showing how the insane should be provided for, and the reputation which we enjoy in this regard is one which is not likely to be lost. With respect, however, to the care of chronic epileptics, the reverse is the case. While epileptic colonies and asylums, both on the Continent and in America are comparatively numerous, it can scarcely be said that in this country any serious effort has as yet been made to deal with the question. As a matter of fact, up to the present there are only three epileptic colonies in England. these, one is at Chalfont, providing for about 50 inmates; another near Liverpool—the Maghull Home -with accommodation for about 150 inmates; and a third at Godalming, providing accommodation for 50

Altogether then, it would seem female epileptics. that throughout the country only two hundred and fifty chronic epileptics can be provided for in special homes for the purpose. It is true that the London County Council intend to have an epileptic colony at their new asylum, now building, on the Horton Manor estate in Surrey, and that something of the same kind will also be carried out in Lancashire by the Chorlton and Manchester Union. Nevertheless, the fact remains that probably many thousands of unfortunate epileptic persons are now living about the country under conditions entirely unsuited to the requirements of their pitiable state. As showing moreover the backwardness which prevails in this regard, men. tion may be made of the fact that in Scotland nothing whatever has been done in the making of provision for chronic epileptics. And yet, as Dr. Ireland points out in an interesting paper upon this subject in the current number of the Scottish Medical and Surgical Journal, there are probably no fewer than six thousand of this unfortunate class of persons in Scotland alone. According to Pelmann's statistics there are fifteen epileptics to every ten thousand of the population, and upon this showing it may readily be gathered, how great is the need for extending and multiplying these epileptic colonies. Dr. Ireland also draws attention to the marked progress which this movement is making in the United States. progress is shown by the following statement of Dr. Powell:-- "During the last two years a wave, a movement, a sentiment, has spread over the United States for segregating epileptics in colonies, provided liberally with land, shops, schools, and expert medical attendants. In 1894 the Craig colony, so well known by reputation in this country, was opened in New York, and a 'national society for the study of epilepsy, and the care and treatment of epileptics' is now doing good work in furtherance of its objects. Part of the duties of the Society is to organise new homes based upon a study of the epileptics' needs, and," quoting from Dr. Powell, "the study of the utilisation of the epileptics' labour, for economic, scientific, and ethical reasons, as well as the study of the educational methods to be employed, including manual, industrial, intellectual, and moral forms and forces." No one who has paid the least attention to the subject can dispute that, apart from all other reasons, upon the common grounds of humanity alone adequate provision for chronic epileptics is an urgent matter of social reform which should claim the attention of the State-Moreover, one feels bound to admit that philanthropy could scarcely find a better outlet than that of making happy the lives of persons whose disease has caused their lot to become so pitiable. We trust that Dr. Ireland will follow up his excellent appeal for help in this direction, in the paper above referred to, by taking some active steps to bring the urgency of the movement before a wider circle than that of the profession, and try and influence the public to see how much philanthropy could do for chronic epileptics.

Rotes on Current Topics.

Cocainisation of the Spinal Cord.

To Professor Bier, of Kiel, belongs the credit for suggesting and practising a new method of procuring what may be termed localised general anæsthesia. Starting with the idea that the injection of a small quantity of cocaine into the spinal canal would suppress, for the time being, the functions of the nerve roots and of the non-medullated nerves contained in the cavity, he put his theory to the test in six patients suffering from surgical lesions, their age varying between eleven and thirty-four years of age. Under the influence of the injections he was able to perform resections, erasions, &c., without pain although consciousness was in no wise affected. He first anæsthetises the soft parts over the lumbar region by the subcutaneous injection of a solution of cocaine and then introduces a fine trocar into the spinal canal by Quincke's method. Through the canula he injects a quantity of solution equivalent to from a fiftieth to a quarter of a grain of the anæsthetic. Within from five to eight minutes of the injection complete analgesia of the lower limbs is produced, which gradually extends to the trunk. In three cases it extended to the nipple, and, in one instance, the subject being a child eleven years of age, it involved the whole of the body, leaving only the head free. Insensitiveness to pain lasted about forty-five minutes, and then gradually disappeared. Sensibility to touch and heat was not affected, but the application of hot bodies did not give rise to pain. No untoward symptoms followed the injections, except in one or two instances vomiting and rather persistent head. ache. Dr. Bier did not hesitate to try the effects of the injections on himself and on his assistant, Dr. Hildebrandt, and in his own case, as the cannula did not fit the trocar with sufficient accuracy, he lost a considerable quantity of cerebro-spinal fluid. This accident gave rise to marked vertigo whenever he assumed the erect position, and this symptom did not subside until after nine days repose in bed. In other respects his experience confirmed that of his patients. We do not suppose that this method of inducing regional anæsthesia is likely, for the time being at any rate, to take the place of general anæsthetics, but, as under strict antiseptic precautions, the procedure appears to be devoid of any immediate or subsequent risk, it might conceivably render service in cases when the administration of chloroform is contra-indicated.

Curly Hair.

The tendency to curliness of the hair is a striking feature in certain individuals, and is characteristic of certain races, but the etiology thereof is one of the physiological conundrums which have hitherto eluded scientific investigation. No subject of original research, however, is too high or too low for a Fellow of the Royal Society and Professor Thomson, at the recent conversazione of that very select body, was enabled to demonstrate the factors underlying the production of curly hair, though he did not go so

far as to define its bearings on character or temperament. He enumerates three factors in the process, a peculiarity of the hair shaft, the action of the hair muscle, and the sebaceous gland. Straight hair is usually circular in section and it is straight because it is cylindrical, a shape which renders it proof against distorting influences. If the shaft, on the contrary, be flat and riband-like, it is unable to resist the pull of the little muscular filament which is attached to each hair root, and this traction gradually modifies the direction of the hair follicle from which it springs. The curve thus produced in the follicle thereafter confers a curve on the growing hair, and as the formation is general curliness results. There is another variety of curliness which is not due to this process, but is more or less intimately associated with the application of metal tongs, heated to a suitable temperature, the effect whereof is to induce asymmetric contraction of the hair shafts. The etiology of this form of haircurl does not stand in need of any scientific explanation, it is merely an outward and visible manifestation of innate vanity with which science has nothing to do. We know that under the influence of powerful emotions, especially those of a disagreeable nature, the hair is apt to become straighter than usual. This is due to the contraction of the hair muscle, and the phenomenon is well rendered in the colloquial phrase expressive of the hair "standing on end." obscure is the not less colloquial phrase which attributes to certain indescribable emotions the effect of "making the hair curl." Of this a scientific explanation is necessary, and, unfortunately, is not forthcoming. Each individual hair may stand on end, like quills upon the fretful porcupine, but science does not afford us any trustworthy clue to the particular circumstances under which the hair will curl in response to an inward psychical disturbance. Obviously Professor Thomson has but touched the fringe of the subject.

Academical Protectionism in France.

THE protectionist policy in regard to foreign students, which was inaugurated in France some two or three years since, is bearing its fruits. In deference to obscure, but none the less efficacious, political considerations the French Government introduced restrictions in respect of the admission of foreign students which threaten to eliminate that inoffensive but not uninteresting individual from French academical circles. Paris medical school had, for many years, occupied an almost unique position in the educational world, though of late the ever increasing progress of the Cerman school has tended to undermine that position. Not satisfied with this natural decay the Government thought proper to decide that, in future, foreign medical students would have to be relegated to the provincial universities and, adding injury to insult, such students were virtually debarred from obtaining the ordinary diploma conferring the right to practise The result has been a steady decrease in medicine. the number of foreigners registered as students in

France. From 1,137 in 1895, the number has steadily diminished to 840 in 1899, and as years go by this number will infallibly undergo still further diminution. Foreigners object to being sent into the provinces when their primary object in coming to France is to avail themselves of the exceptional opportunities for study which the Paris school affords, and they particularly resent the trick of offering them a spurious and valueless diploma in lieu of that accorded to their French colleagues. No better means could be devised for destroying the prestige of the French schools abroad, and if this be the object of these illiberal measures the Government may be congratulated upon their success.

A Comparison in Morality.

CERTAIN French journalists, delighted to find an opportunity of criticising their neighbours, have drawn a very sombre picture of English morality, based on the prevalence of a class of advertisements in the daily and weekly press to which attention has been called somewhat forcibly of late. Much as we deprecate the publication of such advertisements, we cannot admit that they afford prima facie evidence of any widespread demoralisation in our midst. As well might we infer an exalted standard of morality among our neighbours across the Channel from the absence of similar advertisements in their journals. for, curious to relate, none such are to be found in their otherwise impure columns. There is one touch of nature which makes all the world kin, and that is in respect of sexual irregularities. We believe in all sincerity that we are a more moral nation than many others, the French among them; but this does not preclude a certain proportion of incontinent, though possible loyal subjects, and some misguided women who "have stooped to folly, and find too late that men betray " sacrifice money and principle in the vain endeavour to physically rehabilitate themselves. In truth, the publication of these advertisements might justify a slur on our commercial honesty, but certainly not on our morality, seeing that none of the nostrums so speciously brought before the public have in reality any claim to be considered a specific for menstrual irregularity due to physiological causes.

Undertakers' Charges.

Last week a somewhat gruesome find was made in the goods depôt of a London station. The size and weight of a long rough deal case roused the suspicion of the railway officials, who opened the box and disclosed a polished pine coffin, with a brass name plate bearing an inscription. Inquiry showed that the coffin contained the body of a young actor who had died recently of pneumonia while touring in the provinces. As he was in poor circumstances, and his comrades wished to save expense, they resorted to this novel way of removal. It is stated that the carriage of the case was 16s. 2d., while the removal of the body over the same distance would have been £11 19s. This incident shows up in a ghastly fashion the way that the railway companies

extort money from the friends and relatives of dead The disproportion between the carriage of the deal case and the coffin is monstrous and cruel. After the strolling actors had paid the undertaker's charges, it was hardly likely they would be able to find the wherewithal to fill the greedy maw of the railway monopolists, to whom death appears to be a mere signal for plunder. The only thing we know of that at all compares with the funeral carriage railway rates is the bloodsucking of the undertakers. Taking advantage of the outburst of sorrow-stricken helplessness that follows, or should follow, the death of a near one, they proceed to fleece the friends in a way that is little short of criminal. Charges and fees rain down freely as April showers. To our mind one of the most rational institutions in the United Kingdom is the Funeral Reform Association. It is to be hoped that the excellent body in question will turn its attention to the question of railway tariffs for the dead.

Election of Examiners at the Royal College of Surgeons, Ireland.

THESE annual elections took place, in accordance with the Charters of the College, on Tuesday, the 2nd inst. These Charters prescribe that, at this date, the Council of the College may, if it thinks fit, resolve to declare any Professorship in the College to be vacant, but, should they omit to do so, the Professors retain their offices, ipso facto for another year. Within the memory of the College no Chair has thus been declared vacant, friendly hints having always proved sufficient to obtain the resignation of any Professor who was not regarded as capable. On this occasion no Chair was declared vacant.

The election of Examiners caused a very close contest in respect of the Surgery, Midwifery, and Ophthalmology Courts. For Anatomy the outgoing Examiners, Professor Bermingham and Fraser, were re-elected, as were also those in Physiology, Histology, Biology, Pathology, Chemistry and Dentistry. For the two Surgical Examinerships previously held by Professor Stoker and Mr. Patteson seven candidates presented themselves, including Mr. H. G. Croly, Mr. F. Conway Dwyer, Mr. MacFeely, Mr. Dallas Pratt, and Mr. Edward Taylor, and it has transpired that the result depended on a casting vote. In effect, Mr. Croly and Mr. Conway Dwyer were elected, succeeding the two out-going examiners. For the Midwifery Examinership there were four competitors, Mr. Hearn, Mr. Fred Kidd, Mr. Alfred Smith (the outgoing examiner), and Mr. Stevens. In the end, Mr. Kidd was elected after a spirited contest. For the position of Exmainers in Ophthalmology three candidates offered themselves, viz., Messrs. Arthur Benson, who had resigned his seat on the Council to become eligible, Mr. Maxwell, and Mr. Louis Werner. The two lastnamed gentlemen were chosen. There was also close competition for Examiners in the Preliminary Education Court, Mr. J. L. Woodroffe and Mr. John Fraser being eventually elected.

Watering the Streets.

Some different method of watering the streets and highways is urgently called for, and the matter should be taken into careful consideration by the vestries and other authorities concerned. The haphazard method of sending the contractors' water carts round the thoroughfares, as at present obtains. is, perhaps, just the worst method of achieving the objects aimed at from a sanitary point of view. Much of the foulness of the air pervading the streets in summer is due to the decomposition of the mud in the hot sunshine after the water carts have rendered Filth on the streets in a dry state has no obnoxious effluvia, and does no harm to the public health, unless, perhaps, it is disturbed by winds and deposited in the form of dust. On the other hand, foul emanations arising from moist decomposing mud are offensive to the olfactory sense, even if they are not directly harmful, and, moreover, to provide a culture ground for pathogenic bacteria, such as the water-carts afford by the moisture they disseminate, is distinctly objectionable upon scientific as well as hygienic grounds. We are glad to see that some steps have been taken to raise this matter again by members of the profession. The Lewisham Board of Works have been memorialised by a number of medical men in the south-east suburbs, who point out the injuriousness of the present system, and suggest that the roads should only be watered in the early mornings and then thoroughly swept. In this suggestion we heartily concur, and now that the roadways and thoroughfares are so much occupied by cyclists it is important, in the public safety, that the watering process should be carried out at a time when it does not constitute a risk to "wheelmen." The treacherous, slippery surface of a freshly watered dirty thoroughfare has, upon many occasions, been the direct cause of loss of life to unwary cyclists.

Stamp-lickers' Tongue.

A COMMENTARY upon the paragraph which appeared in our issue of last week was in circulation at the very moment of our going to press. A case of fatal blood-poisoning occurred at Preston, and was the subject of a coroner's inquiry at Fleetwood. The deceased had a wounded knee, to which a piece of stamp-paper had been applied, and it was suggested that the cause of death was to be found in the gum. Dealing with this point, the Postmaster-General last week wrote to the coroner saying that pieces of the paper in question had been examined, both biologically and chemically, in the Government laboratory without detection of any irritant substance. There was no evidence that the gummed stamp-paper at present in use was capable of setting up blood poisoning, and it was unlikely that the death of deceased was in any way connected with the application of the stamp. all due deference to the Postmaster-General we should like to ask that distinguished official of what the sticky substance of postage stamps is composed? Is it or is it not, as alleged, obtained from the serum of the horse? If so, are any special steps taken to exclude bacterial contamination? A plain answer to these plain questions is clearly within the grasp of the scientific advisers of the Post Office, and will go far to allay the public curiosity upon a subject which has a direct bearing upon every citizen of this vast empire, to say nothing of the rest of the world beyond seas.

Œsophagismus.

ŒSOPHAGISMUS is a very rare condition, and its etiology is involved in considerable obscurity. That its occurrence, however, is associated with the abuse of tobacco, as has been stated, receives some confirmation from a case recorded by Dr. Lowe in the current number of the Inter-Colonial Medical Journal of Australia. The patient was a labourer, whose history was that he could only force food into his stomach by taking a pint or so of water afterwards. The difficulty of swallowing had persisted for three years and a half, and it would generally occur several times during a meal. If he could not force the food down by taking fluid, regurgitation would follow, and nothing would pass into the stomach. The condition, he complained, was becoming worse, so much so that at the present time he was obliged to leave the table about three times during a meal in order to force the food down or allow it to regurgitate. There was no history of hypochondriasis, syphilis, injury, gout, or rheumatism, and the health in other respects was good. A probe-pointed bougie could be easily passed into the stomach, and there was no evidence of æsophageal stricture or of any organic disease. The only detail of importance to be obtained from the history was that the patient had been an excessive smoker. The author merely records the case without saying whether he had attempted anything in the matter of treatment.

No Medical Privilege.

CONSIDERABLE curiosity was excited in medical circles by a paragraph which went the round of the press a short time since relating to the acquittal of a Gosport practitioner of a charge of riding his bicycle on the footpath, in virtue, it was alleged, of an old Act of Parliament which authorised medical men, on their way to an urgent case, to take the shortest route. We learn from the organ of the Cyclists' Touring Club that the statement in question belongs to the category of "pure inventions." When called upon to answer the charge, the practitioner in question gave it as his "impression" that an old statute existed which authorised his violation of police regulations and the hearing of the case was adjourned to admit of the production of the Act. As was to be expected. it was not forthcoming, but the magistrates consented to dismiss the case upon payment of costs, coupled with the injunction that the defendant should go and sin no more.

The Mechanical Dispenser.

Some one who can afford to advertise in the *Times* for pleasure and not apparently for profit has been poking fun at the firm of Boots and Co., who have

been running a score of branch chemists' shops with the aid of unqualified assistants. The firm is now threatened with the extinction of this line of business by the possible passing of the Companies Act Amendment Bill, and, being naturally anxious in mind at the prospective loss, is offered by advertisement the following kindly suggestion:—"To Inventors.—Wanted, for the use of limited liability drug companies, a mechanical arrangement (incapable of qualification) to facilitate the delivery across the counter of articles subject to the obstructive provisions of the Pharmacy Act, so as to afford a convenient means of free trade distribution. Very liberal terms offered for a machine that would secure perfect immunity for companies.—Apply to Boots, care of Mr. John Smith, 123A, Dashwood House, Broad Street, E.C."

London School of Tropical Medicine.

THE dinner, at which the Right Hop. Mr. Chamberlain will preside this (Wednesday) evening, at the Hotel Cecil, in connection with the London School of Tropical Medicine, gives promise of a decided success, both financially and socially. The Lord Chamberlain, Lord Lister, Lord Strathcona and Mount Royal, and the Marquess of Lorne have intimated their intention of being present, and the extensive resources of this large hotel are expected to be tested to the Among the contributors to the fund for the School are the Colonial Office, £3,550; the Bishop of London (Marriott Bequest), £2,000; the King of the Belgians, £200. The Japanese Embassy has also consented to allow their new battleship, the 'Shikishima, to be exhibited for the benefit of the charity previous to its leaving the Thames.

Oyez! Oyez! Oyez!

WE are requested to publish the following announcement: "Their Royal Highnesses the Duke and Duchess of York have consented to open the new building of the Royal London Ophthalmic Hospital, alias the Moorfields Eye Hospital. The new building is in City Road, about one mile from the present site in Blomfield Street. Provision is being made for forty additional beds, and for a much larger outpatient department. The hospital at present relieves over 400 cases a day." If any of our readers can find in the two concluding sentences any source of satisfaction they are to be congratulated. To the profession at large this ever-increasing pauperisation of the public is a perpetual menace.

The Prevention of Consumption.

The great statutory general meeting of the National Association for the Prevention of Consumption and other forms of Tuberculosis was held on the 4th inst., the Earl of Derby in the chair. Dr. St. Clair Thompson read the report of the organising committee and defined the scope of the work before them. He announced that 1,252 members had already been enrolled, and 25 branches had been formed, chiefly through the action of medical societies. The financial situation was satisfactory and on motion from the chair the report was adopted and the council elected.

The Sensational Performance Again.

LAST week the recurring scandal of the "shocking" accident to the acrobat took place before the eyes of a public audience at the Alexandra Palace, London. A performer who goes by the name of the "American Blondin," after a series of daring feats on a tight rope at a height of a hundred feet, went to the roof of the huge building to take his "long dive" into a net stretched below. On rebounding to some height he struck for a second time the net, which gave way, and he was dashed with great force into the orchestra stalls. He had a leg broken and was terribly injured about the head and body. It is said that the poor fellow had talked of the possibility of an accident, and only lately said he hoped a big crowd would see it if The reason for this curious ever it happened. wish may have been simple vanity, but there is no hope left that the sight of such accidents will ever fill the mind of the public with disgust at this kind of amusement. A list of the persons killed in public performances during the last fifteen years would afford a good deal of reflection for the student of human nature. How is it Government does not step in and stop this waste of human life for the open and avowed purpose of putting money into private pockets? Life is protected in other directions, often in what may be termed an almost grandmotherly fashion; yet here we have an abuse of the most flagrant character allowed to flourish as the green bay tree. Where is the London County Council? When Parliament fails, that energetic body has often come forward to fill the gap. Here is an opportunity for a solid reform by way of control and licensing of places of public amusement.

The Dundrum (Co. Dublin) Cause Celebre.

The hotly-discussed question of the election of a Medical Officer to this district, referred to more than once in these columns, has been finally settled by the appointment of a Dr. Carroll. It will be recollected that a previous election was declared void by the Local Government Board on the ground of "irregularity," the fault consisting in the absence of a voter which was obtained by a bogus telegram. We cannot blame the Local Government Board for having quashed the proceedings under the circumstances, but the point of the business is that the candidate who had been formally elected on the occasion was, by this decision, ousted from every chance of occupying the coveted position, although the Local Government Board itself admitted that he was, in all respects, a desirable selection. Both he and his rival competitor were told that they might compete at the new election; but everyone knew that this intimation only added insult to their injury, because there was not the faintest shadow of a chance that either of them would succeed. In the interval between the two elections the operation of the Irish Local Government Act had created a complete bouleversement, the religion and politics of the elective constituency (the only consideration which determines a dispensary election in Ireland) having diametrically changed. The effect of the decision of the Local Government

Board has been to deprive the previous successful candidate of the professional income to which he had been looking forward for over twenty years, and he has our hearty sympathy. What is of more importance to the Poor-law Medical Officers of Ireland is that by this case it seems to be established that the Local Government Board has absolute power, without giving any reason, by the simple process of refusing its sanction, a very serious matter indeed for candidates without friends.

Patent Medicine Frauds.

A MAN named Grigor was prosecuted a few days ago at Bow Street Police Court, London, for having obtained money on the false pretence that a certain nostrum compounded by him, which he calls "Varixia," is a sovereign cure for varicose veins. It transpired that the stuff is a weak solution of Witch Hazel, and, of course, perfectly inert, and that it was made up for him by a chemist for 2½d., bottle all complete, and sold at 2s. 9d. His own defence was as follows: "Many patent medicines are absolute frauds. They owe their success not to their merits but to extensive advertising." He was remanded.

An Improvised Stomach Pump.

Dr. Burns, of Sunderland, who was called to a man who had attempted suicide by swallowing rat poison, found himself in a dilemma owing to his not being provided with a stomach pump. Nothing daunted, he is reported to have passed a tube into the stomach of the patient, and to have sucked out the contents, thus saving his life.

THE Royal Zoological Society of Ireland has issued invitations for a Garden Party on May 19th, for the opening of the new building erected to perpetuate, in the gardens, the memory of the Revd. Prof. Haughton. The Lord Lieutenant and Countess Cadogan have promised to be present, and the meeting is to be addressed by His Excellency and by Lord Roberts and Sir Thomas Ball. We avail ourselves of this opportunity to congratulate the Society upon its recent activity and prosperity. The new Hon. Sec., Prof. Cunningham, is a host in himself, and is ably assisted by new Councillors. and the last report issued by the Council is, in style and material contents, quite a different product from its predecessors. If the administration persists in this policy it will speedily restore to the Gardens their lost popularity.

THE date for the opening of the new building of the Royal London Ophthalmic Hospital, in City Road, by the Duke and Duchess of York, is Monday, June 26th.

PERSONAL.

Mr. Robert Stroyan, who died last week at Johannesburg, has bequeathed £2,000 to the Norwich Hospital.

Mr. Brydges Williams has contributed a donation of £5,000 to the Prince of Wales's Hospital Fund.

Mr. Francis Sanderson Morrison, F.R.C.S.Irel., of Dundalk, has announced his candidature for the Council of the Irish College of Surgeons in the interest specially of the provincial Fellows.

MR. ALBAN DORAN, F.R.C.S., will be the Orator at the annual conversazione of the Medical Society of London on Monday next. He has chosen "Shakespeare and the Medical Society" as his subject.

Miss S. F. Fox, of Wimbledon, headed the list at the last occasion of conferring degrees at the Durham University, and she also took honours in the first examination for the degree of M.B.

THE Dean of the Medical Faculty of Edinburgh University, Dr. T. R. Fraser, has returned from his duties as President of the Plague Commission; he met with an enthusiastic reception from his large class of students.

It is understood that Dr. D. A. Welsh, assistant to the Professor of Pathology in Edinburgh and Pathologist to the Royal Infirmary, is a candidate for the post of Professor of Pathology in Dundee, rendered vacant by Professor Muir's translation to Glasgow.

SIR W. H. FLOWER, the newly elected President of the Zoological Society, was in his younger days an Army surgeon, and went through the Crimean campaign. He was subsequently appointed Assistant-Surgeon to the Middlesex Hospital.

Mr. R. B. McCausland, M.B., F.R.C.S., surgeon to Stevens' Hospital, Dublin, has announced himself as a candidate for a seat on the Council of the Royal College of Surgeons, Ireland, at the coming election on the first Monday in June.

DR. WALTER ESEX WYNTER, F.R.C.P., has been appointed Lecturer on Pharmacology and Therapeutics at the Middlesex Hospital Medical School, and Mr. Alex. G. R. Foulerton, F.R.C.S., D. Ph. Lecturer on Public Health at the same institution.

SURGEON-GENERAL SIR W. GUYER HUNTER, K.C.M.G., will take the chair at the annual dinner of the Indian Medical Service at the Hotel Cecil on June 8th. The Hon. Sec. is Mr. P. J. Freyer, 46, Harley Street, London, to whom all communications should be addressed.

Dr. Grorge Johnston Stoney, some time chief in the laboratory of Lord Rosse's great telescope in King's County, afterwards Secretery to the Queen's University in Ireland for several years, and well known in other capacities as a very distinguished scientist, has been awarded by the Royal Dublin Society the first "Royle" medal ever struck, in consideration of his most valuable publications on Boyle and Marriott's law.

The late Sir B. W. Richardson, M.D., F.R.S., who in his day was known as the Apostle of Temperance, is to have a Memorial Brass unveiled to his memory at the London Temperance Hospital on Thursday, the 18th inst. The Medical Temperance Association, of which he was for some years president, originated the idea, and few who have worked for the cause deserved the honour more. Dr. Sims Woodhead, Dr. Clark, M.P., and other members of the profession will take part in the ceremonial.

Scotland.

FROM OUR OWN CORRESPONDENT.

EDINBURGH UNIVERSITY.

FROM a report recently issued by the General Council, it appears that the number of students attending the University continues steadily to decline. The total number in 1890-1 was 3,488; in 1897-8, 2,780. The fall is most conspicuous in the medical faculty (from 1,951 to 1,405) and in arts. In the latter, however, the docrease of 200 is more apparent than real, and is due to the There is a concreation of a faculty of science in 1893. siderable decrease in the number of divinity students, number of those studying law mained pretty constant. In contrast to the dimi-nution in the number of students, it is note-worthy that the expenditure (now under the control of the University Court) on salaries to principal, professors, lecturers, assistants, and examiners has increased from £48,167 to £54,213. The principal and professors only benefit by the increase to the extent of some £1,600, while the salaries of lecturers amount to £4,798, as compared with £1,226 nine years ago. Steps are at last being taken to catalogue the University library. The work will, of course, take a good many years and cost much money, but it will incomparably increase the value of the library. Two University chairs, History and Physiology, are now vacant.

MEDICAL STUDENTS AND GLASGOW FEVER HOSPITALS. - Should Fees be Charged?—Dr. Johnston, Medical Superintendent of Belvedere Hospital, has reported to the Corporation Hospitals Committee on the question of clinical instruction in the City fever hospitals to students attending the medical schools in Glasgow. was pointed out by the superintendent, in tabular form, that the attendance was increased from 38 in 1893 to 127 in 1897-98. Formerly it was not compulsory for students to attend fever wards or hospitals of that kind, but now the new regulations of the General Medical Council make it compulory on all medical students in their fourth year to attend cliniques and lectures on fever and infectious diseases, and the medical superintendent (and lecturer) in order to meet the increased number of students was obliged to increase his classes from two to five, and latterly to seven, which, he says, is the maximum number that he is capable of undertaking. Further, the number of students are increasing steadily, and the period of time over which the course of instruction extends has been prolonged, until only two months (August and September) in the year are quite free from regular classes. The Medical Superintendent says it is worthy of note that, so far as he is aware, no student has ever carried infection from the hospitals, or contracted any infectious disease during the period of attendance at the cliniques. Now infectious disease the question arises: Should the Corporation charge the students a fee for their instruction on fevers? students naturally feel this an extra call on their already overtaxed pockets, and it is pointed out that it will be an advantage to the community for the practitioners of the future to become familiar with the symptoms and appearance of fevers, &c.; they will be better able to diagnose them at an early stage, and so assist sanitation. We do not say that a fee should not be charged for the advantages derived in being taught the practical part of infectious diseases, but let it be a modified fee. The fee for reporting a case of infectious disease is 2s. 6d., and a penalty of 40s. for not reporting, which seems somewhat absurd, and should be modified, when it is remembered that measles, although an infectious disease, is not included in the list of such for report. It is to be hoped that the Corporation will be able to see their way to save the already overburdened student from this extra

THE DUNDER MEDICAL SCHOOL.—Dundee possesses an excellently equipped medical school, and is not unnaturally anxious to attract a large number of students. Owing to the transference of Dr. Muir to Glasgow University, his chair at Dundee is vacant, and University Jottings suggests that Dundee could not get a

CORRESPONDENCE.

teacher with a more attractive personality than Dr. Sutherland, assistant to the Professor of Pathology in Glasgow University, who is among the number of applicants for the Chair of Pathology in Dundee College.

Typhoid Epidemic.—An outbreak of typhoid fever has taken place in Bathgate, a mining locality some little distance from Glasgow. At the outset the subjects were seized with influenza, but after a week or, in many cases, fourteen days, the well marked appearance of typhoid fever showed itself. This peculiarity seems to have misled practitioners of the district, who returned the cases as influenza. During the past three weeks more than thirty cases have been reported, and several deaths have taken place. Since the recognition of the disease the cause of the outbreak has been discovered to be due to the water supply, and is causing much alarm.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday evening last commenced as general meeting for the election of officers, &c., Dr. F. T. Roberts being elected President for the ensuing year.

The first thing after the routine business had been disposed of was a report by Messrs. Gould, Sheild, and Stanley Boyd in reference to Mr. Battle's case, illustrating "the value of Coley's fluid for inoperable tumours." Having read the hospital notes of the case, and the published accounts and examined microscopical specimens prepared by Mr. Shattock, they formulated the following conclusions:—(1) That the pathological appearances were not conclusive; (2) that the clinical history did not exclude syphilis; and (3) that in view of the extreme difficulty of accurately diagnosing sarcoma from inflammatory formations only those cases the nature of which had been indisputably proved should be admitted as evidence of the value of any therapeutical measure.

TWENTY CASES OF ENCYSTED VESICAL CALCULI.

Mr. Bruce Clarke pointed out that in these cases where the stone is fixed to the bladder wall the usual symptoms of stone are absent, hæmaturia and pain rarely occur, and cystitis is usually the only symptom with which these cases are associated. At an early stage the symptoms they present are assumed to be due to some other cause, and the stone is often only detected when the bladder is opened. This was so in half the cases he then related The exact position of the stone in the bladder wall varies considerably. Some are imbedded in the prostate, and some lie loose in cysts in other parts of the bladder, but these cysts are usually found near its base. The author showed that most of these cases occurred in persons between the age of 60 and 70, and insisted on the desirability of exploring doubtful cases of cystitis which do not yield to ordinary methods of

Mr Swinford Edwards concurred in praise of suprapubic exploration, and deprecated attempts to crush encysted calculi in situ.

Mr. Buckston Brown insisted on the importance of distinguishing between sacculi and pouches, pointing out that though a stone in a post-prostatic pouch could be removed suprapubically without laceration of the bladder wall, that was not the case with a really encysted calculus.

Mr. Freyer said he had operated on nearly 1,000 cases of stone in the bladder, and had only met with 20 or 25 instances of encysted stone. He pointed out that when the opening connecting the pouch with the bladder was small, a cutting operation was necessary, preferably the suprapubic operation, but if the opening were large the stone could be dealt with in situ. In 400 operations for stone on patients of all ages, with stones of all sizes, a cutting operation had only been found necessary in 8.

Mr. F. Eve related two cases of Resection of the Large Intestine with Recovery, and a discussion ensued, in which Mr. Battle and Mr. Wallis argued against the use of a button or bobbin in anastomosis of the large intestine, both surgeons preferring lateral anastomosis by suture.

Correspondence,

We do not hold ourselves responsible for the opinions of our

THE ATTENUATION OF SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR SIR,-Dr. George Ogilvie asserts in the MEDICAL Press and Circular of May 3rd, that the "similarity" of the aggravated form of disease among British troops invalided home from India, to that depicted by Fergusson in Portugal, was first pointed out by himself, and states that my statement "in proof of the truth of Fergusson's views that the similarity of the aggravated form of disease among British troops invalided home from India was originally adduced by myself" "is a

production of daring imagination, a fiction, &c.

In the Lance of Jan. 29th, 1898, I stated that
"Dr. Ogilvie considers that the sad state of the
British Army at the present time in India (which I might say is a counterpart to the state Army noted by Fergusson in Portugal, is sufficient to considerably shake any theory of general immunity. The observations of William Fergusson (not Ferguson), for two years the Inspector of Hospitals to the Portuguese Army, seem to me to be so conclusive, and, moreover, verified at the time by Staff Surgeon Jebb that it is impossible to accept Dr. Ogilvie's interpretation." I repeat it was impossible. In Dr. Ogilvie's paper in the British Journal of Dermatology, November, 1897, and, as Dr. Ogilvie states, noticed in the Lancet, he had discredited Fergusson's observations on mitigated disease in Portugal in 1812; had enunciated the view that "the hereditary transmission of syphilitic immunity was a remote possibility, and that the attenuation of syphilis, whenever it takes place, is affected by the improvement in hygienic preventive and therapeutic measures (ride his letter, Lancet, March 5th, 1898). one word had he said of Fergusson's native views of climate or noted causes of mitigation of syphilis, and while Dr. Ogilvie noted the sad state of the British troops invalided home from India; subscribed to the explanation of malignancy by lack of hygienic preventive and therapeutic measures as opposed rypished present the approximation of control of syphilis among British troops depicted by Fergusson in Portugal, nor his explanation of climate with its "febrile affections," intemperance, &c.

Such conclusions and omissions, obviously founded

upon imperfect knowledge of Fergusson's work, led me to direct attention to the work of this great Army Surgeon in the fourth volume of the Transactions of the Royal Medical and Chirurgical Society, not only in justice to his name and work, but in favour of the many

causes of mitigation and aggravation of syphilis.

In the Lancet of April 23rd, 1898, in defence again of Fergusson, I state: "He advanced the alternative view of climate (malaria) and intemperance to account for increased virulence, either of which theories may apply at the present day." Again, May 24th, as opposed to mercurial abuses.

On the other hand, Dr. Ogilvie, in his paper in the British Journal of Dermatology, July, 1898, in noting the aggravated form of syphilis in troops invalided home from India states, "The resemblance this description bears to Fergusson's narration is striking." Again, in the British Medical Journal, of November 19, 1898, he asserts, "In my paper on syphilis among British troops, Portugal, 1812, India 1896, to which you refer in the British Medical Journal of November 5, I have pointed out that there exists a striking resemblance between the state of affairs among British troops in Portugal, 1812, as described by Fergusson, and the state of affairs among British troops in India, 1896." On both occasions this similarity is used by Dr. Ogilvie to further his contention that malignancy is explainable by lack of hygienic pre-Fergusson later admitted the aggravation of syphilis among British troops in Portugal by the abuse of mercury, so now, perhaps, "a similar cause might be operative in India." ventive and therapeutic measures, and that whereas

Unless Dr. Ogilvie has noted the "similarity" anywhere else previous to my letter in the *Lancet*; of Jan. 29th, 1898,, I repeat the "similarity" was originally adduced by myself, and in proof of the truth of Fergusson's observations and views respecting malaria as an aggravating factor in the foreigner, and in no way inconsistent with attenuation in the native.

2. With regard to Prof. Neumann and Dr. Ogilvie's remarkable statements, I think if your readers will refer to Dr. Ogilvie's paper they will find my remarks in the MEDICAL PRESS AND CIRCULER, March 1st, correct.

Dr. Ogilvie's statement in his paper as opposed to that in the MEDICAL PRESS AND CIRCULAR is as follows:— Prof. Neumann in his historical introduction, "says that Portugal is 'less infected' with syphilis with regard to the intensity of the disease as well as its extent, that the intensity of the disease as well as its extent, that the course of the disease is a very favourable" one, that "spontaneous cure is not rare," that this benign character of the disease is apparent in the hospitals, that he, therefore, is in opposition to Fergusson, who "pointed out the malignancy (?) of syphilis in Portugal." This latter statement is evidently a slip of the memory excusable in so bulky a work. The note of interrogation is Dr. Ogilvie's, and he here clearly objects to the statement that Fergusson pointed out malignancy in Portugal. But Fergusson, corroborated by Guthrie did point out malignancy in corroborated by Guthrie, did point out malignancy in Lisbon, in contradistinction to the attenuation noted in the bulk of the people, and I assumed that Neumann, being aware of this, found himself in opposition, and deliberately stated it, and that it was not a slip of the memory as Dr. Ogilvie supposed. Dr. Ogilvie now states that Neumann has corrected the statement as a misprint, which I regret, for from this as well as from his previous views noted by Dr. Ogilvie discrediting Fergusson's observations on mitigated disease in Portugal, I fear he is not fully acquainted with Fergussons remarkable work. Dr. Ogilvie thinks it a curious malady to show extremes between "very mild" and "malignant," but there is no inconsistency in Fergusson's observations, because it is known that in seaport towns, e.g., Lisbon, syphilis from various causes assumes for the most part an aggravated form.

3 With regard to Professor Tarnowsky (St. Petersburg) Dr. Ordivides professor townsky the statement

burg), Dr. Ogilvie does not quote correctly the statement which appealed to me in favour of transmitted hereditary immunity. He states that Tarnowsky relates "thirty cases of syphilis in the majority of which both parents and children had acquired syphilis," whereas my quotation is "in syphilis which never enters the gummatous period, and which is even exclusively limited to the initial symptoms abortive syphilis so to say, parental syphilis has transmitted a lesser receptivity to the syphilitic diathesis." I must leave it to your readers to judge for themselves the importance of such a statement, and to compare it with the apparently contradictory opinion Dr. Ogilvie quotes from the same authority. While adhering to transmitted immunity as one cause of modified syphilis, I deny, and have denied that it is the only cause. Dr Ogilvie limits his interpretation of attenuation to "acquired immunity, hereditarily transmitted." mitted," whereas it has been my endeavour to direct attention afresh not only to modified syphilis, but to the many causes of attenuation, apart from the question of treatment.

4. With regard to Dr. Ogilvie's complaint that I have unfairly drawn attention to his wrong spelling of Fergusson's name, which he says was done by mistake, and that I have not done so to others, the point is that it is Dr. Ogilvie who professed to throw discredit on Fergusson and his views, presumably with a full acquaintance of Fergusson's original work; whereas in this first paper there is no evidence of such; and the repeated incorrect spelling of Fergusson's name supports this

incorrect spelling of Fergusson's name supports this view, which Dr. Ogilvie has not thought fit to deny.

On the contrary, the late Mr. Henry Lee's conclusions and appreciation of Fergusson's work were founded on knowledge of Fergusson's original work. The mistake in the spelling of the name occurring in his chapter in his work "On Syphilis," was occasioned, as he informed me, through his having written this chapter (1862) from memory of Fergusson's original work. This will be at

once evident to those who are acquainted with the published lectures of Mr. Lee, delivered at the Lock Hospital in 1854, in which the name of Fergusson is spelt correctly.

I am, Sir, yours truly,
John A. Shaw-Mackenzie. May 6th, 1899.

"THE ANTI-VIVISECTION GALA,"

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIE,—Your leader on this subject has at least the merit of being good tempered, and, therefore, I am induced to put in a word to say that I am the "eminent surgeon" who took part in the function and against whom you perpetrate at least two mistakes. You seem to think that my conversion to anti-vivisection views is a recent matter, but it is a matter of nearly thirty years old. My first contribution to the literature of the subject was made twenty-six years ago, and the paper, which has been made a kind of text-book for the cult is eighteen years old, has appeared in nearly a dozen different languages, with combined issues of some half a million copies. If such a connection could bring about the fall for which you obscurely prophesy, I should have felt it long ago; yet, strangely enough, I never did. On the contrary, when the paper was read I had only one medical supporter, a woman, whilst now I could command hundreds.

Some day I shall have a tombstone put over me and an inscription upon it. I want only one thing recorded on it, and that to the effect that "he laboured to divert his profession from the blundering which has resulted from the performance of experiments on the sub-human groups of animal life, in the hope that they would shed light on the aberrant physiology of the human groups." Such experiments never have succeeded, and never can; and they have, as in the cases of Koch, Pasteur, and Lister, not only hindered true progress, but they have covered our profession with ridicule.

I am, Sir, yours truly,

LAWSON TAIT.

195, Newhall Street, Birmingham.

[How anyone can gainsay the unquestionable benefit to science of observations on living animals surpasses our comprehension. We are driven to the conclusion that Mr. Tait and his fellow anti-vivisectionists have a blind spot in their mental retinæ.—ED.]

MEDICAL AID ASSOCIATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think it is evident that the Medical Aid Officer has totally misinterpreted the letters that have appeared on the subject. Speaking for myself I have in no instance dealt with the question of salaries. In fact I submit that the remuneration received by medical offiers is hardly worth commenting upon. What is most objectionable is the system of canvassing for patients. I feel sure that "Medical Aid Officer" will not be prepared to defend a system whereby medical men build up practices by filching other practitioners' patients. I am not generally in the habit of using "heated" language in my correspondence, and I venture to appeal to you, sir, whether I have done so in this particular instance. It may interest the "Medical Aid Officer" to know that at a very largely attended meeting of the South Wales Branch of the British Medical Association held at Newport on May 2nd, a resolution that I proposed on the subject of medical aid associations was considered too mild, and that one was actually proposed and unani-mously carried asking the General Medical Council to declare it "infamous conduct in a professional sense

How can we possibly expect the working classes to consider ours a dignified profession when they find men willing to ally their names to associations whose existence entirely depends on a house-to-house visitation?

It may be convenient for some of the leaders of the profession to ignore the existence of the evil, but I would like to point out that serious diseases are not usually cured by ignoring their presence.

I am, Sir, yours truly, 99. T. GARRETT HORDER. Cardiff, May 3rd, 1999.

Obituarn.

DR. JOHN EUSTACE, OF DUBLIN.

THE death of this much esteemed gentleman, at the ripe age of seventy-nine, has been announced within the last week. He and his brother—dead now for many years—were specialists in Psychology, and the joint proprietors of two private asylums, situated at Drumcondra, near Dublin, which establishments Dr. John Eustace held until his death. His qualification of M.B. and M.D. of the University of Dublin, dated from 1851. He was a member of the Society of Friends, and was universally respected, not only for his integrity, but for his business capacity and his geniality and kindliness.

Parliamentary Aews.

Vaccination.—Sir W. Priestley (Edinburgh and St. Andrews Universities) asked the President of the Local Government Board whether it was true that in Ipswich and other localities, where previously there had been great opposition to vaccination, the cases of vaccination had notably increased since the passing of the Act of last year, and that many parents who had been per-suaded to apply for certificates of exemption had not presented them to the vaccinating officer, but had subsequently had their children vaccinated. Mr. Chaplin, in reply, said there was distinct evidence that in a number of localities where previously there had been a great amount of default under the Vaccination Acts the number of vaccinations performed since the new Vaccination Act came into operation on January 1st last has been in excess of that for any corresponding period in recent years. In respect of Ipswich, the average quarterly number of vaccinations performed by the Public Vaccinator during 1897 and 1898 was only 33, whereas in the first quarter of the present year the number vaccinated was 198 Mr. Chaplin, in reply to Mr. Webster, stated that according to the latest information it was not the fact that during the present small-pox epidemic in Hull all the cases admitted to the hospital—which were 26 and not 25—were unvaccinated. Nineteen had been vaccinated, and the Medical Officer of Health reports these cases to be of a modified character and that none had died. (Cheers.) The remaining seven were unvaccinated; of these four had died. He had no means of estimating the proportion of unvaccinated persons of all ages in Hull, but during the last five years for which returns have been received some 20 per cent. of the children whose births were registered in the two Unions in which Hull is comprised, and who survived when the returns were made, were then unvaccinated.

MEDICAL OFFICER FOR THE EDUCATION DEPARTMENT. The Committee of Council of Education have decided not to appoint a Medical Officer to deal with public health questions that are constantly occurring in connection with elementary schools, but propose for the pre-sent, at any rate, to refer matters under the Superannua-tion Act to the Medical Officer emoloyed by the Post Office and the Civil Service Commissioners.

Medical News and Pass Lists. Medical Defence Onion.

The following officers of the Union have been reappointed for the year:—President, Dr. W. S. A. Griffith, F.R.C.P.; treasurer, Dr. J. A. Masters, M.R.C.P.; hon. sec., Dr. Campbell Pope, F.R.C.S.; general secretary, A. G. Bateman, M.B.

THE following members have been elected vice-presidents of the Union, and, together with the executive officers and elected members, form the Council of the Union:—Mr. Gunton Alderton, L.R.C.P.; Mr. C. A. Union:—Mr. Gunton Alderton, L.R.C.P.; Mr. C. A. Ballance, F.R.C.S.; Dr. Edgar Barnes; Dr. James Barr, M. 3.C.P.; Mr. James Bisshop, L.R.C.P.; Mr. A. H. Dr. Reginald Dr. Frederick Nicholls; Dr. Edward Nix; Dr. Reginald Pratt; Dr. F. A. Purcell; Dr. Prior Purvis; Dr. Walter Rigden; Dr. R. Saundby, F.R.C.P.; Dr. F. J. Wethered, F.R.C.P.

THE MEDICAL PRESS.

The French Hospital and Dispensary.

THE thirty-first annual dinner on behalf of the funds of this institution took place on Saturday, the 6th inst, at the Hotel Cecil, M. Paul Cambon, the French Ambassador, in the chair, supported by the Lord Mayor of London and Sheriffs, and by many members of the corps diplomatique. The chairman said he had himself had an opportunity of inspecting the hospital, and had been greatly impressed by the ample provision for the care of the sick. He also spoke on terms of commendation of the convalescent home which had been recently opened at Brighton in connection with the hospital. He conat Brighton in connection with the hospital. gratulated them upon living at the latter half of the century, than which he believed at no time had social, Christian and charitable sentiments more stirred the hearts of men. The Italian Ambassador responded to the toast in French. He pointed out that the hospital received not only French sufferers but sufferers of all nationalities. He alluded to a certain minister who was repreached for having appointed as surgeon to a vacant post a candidate who had not obtained the highest marks at the competitive examination. On being pressed to defend his selection he said that the candidate in question was the most conservative among the candidates, adding that conservatism in a surgeon was a valuable quality. The Lord Mayor also responded to the toast, which he thought tended to promote feelings of amity and good fellowship between the two peoples. During the evening the secretary, M. Pontdepeyre, announced subscriptions and donations amounting to 23,200. The musical arrangements were under the direction of Chevalier Tito Mattei, who was assisted by Mdlle. Hélène Michaëlis, M. J. Thomas, and Signor Giuseppi Maggi.

FEES FOR ATTENDANCE ON A MEDICAL MAN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The writer has attended a retired medical man at latter's own request, one attendance lasting for seven weeks.

Patient died recently, leaving property, real and personal, to well-to-do relatives and the religious body to which he belonged, but nothing to the writer. As he left neither wife, family. nor poor relations behind, would not writer be justified in sending in a bill as for attendance in the case of an ordinary well-to-do patient? The amount of estate for distribution exceeds £6,000.

I am, Sir, yours truly,

"Dublum."

[We do not hesitate to express the opinion that the case described by our correspondent fully justifies his demanding his fees and enforcing his claim. If his doing so could have been, or could now be, of any injury to his medical confrere or his relatives, our correspondent might judiciously abstain from doing so, but, in our opinion, the circumstances narrated entirely absolve him from the observance of etiquette, and will acquit him of unkind or unsympathetic treatment of the family. We should, however, suggest that, for the sake of his own self-respect his demand ought to be moderate. He would follow the bad example of the family if he made any grasping claim.—Ep.]

PEVENSEY.—A damp upper soil is almost invariably connected with malaria. It is also associated almost certainly with specific diarrhose, with typhoid fever, and in all probability with tuberculosis. Among other possibilities is that of the relation of cancerous diseases to dampness of soil, a theory that is ardently advocated in some quarters. Coming to your question, we should advise you to get a dry and porous soil if you can do so conveniently. If preduded from that course by unavoidable circumstances, the next best thing is to see that the curtilage of your house is well drained and that the basement is absolutely impervious throughout. Subsoil drainage has nearly rid the Fens of ague.

TUBERCULOSIS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—If medical men will urge the preachers and teachers in their respective neighbourhoods to induce breeders of stock to show consideration for the animals under their control two advantages will result—the animals themselves will be happier and better, and the food supplied be wholesomer.

I am, Sir, yours truly,
F. LAWRENCE,
Hon. Sec. Church Sanitary Association.
Westow Vicarage, York, May 7th, 1899.

CURIOSITIES OF THE TELEPHONE,

A CORRESPONDENT sends us the following amusing dialogue, the A CORRESPONDENT sends us the following amusing dialogue, the source of which we regret being unable to acknowledge, not knowing whence it is taken:—"Are you there?" "Yes." "Who are you, please?" "Watt." "What's your name, please?" "Watt's my name." "Yes; what is your name?" "I say my name is Watt." "Oh! Well, I'm coming round to see you this afternoon." "All right. Are you Jones?" "No; I'm Knott." "Wo are you, then, please?" "I'm Knott." "Will you tell me your name, please?" "I'm Will Knott." "Why won't you?" "I say my name is William Knott." "Oh! I beg your pardon." "Then you'll be in this afternoon if I come round, Watt?" "Certainly, Knott." They were then "rung off" by the Exchange.

Meetings of the Societies and Tectures.

STABB, EWEN CARTHEW, F.R.C.S.Eng., Surgeon to Out-patients at the Great Northern Central Hospital.

TAIT, J., L.R.C.P., L.R.C.S.Edin., Medical Officer for the Sharnbrook District of the Bedford Union.

WILSON, A. GAERICK, M.R.C.S.Eng., L.R.C.P.Lond., Junior Outpatient Surgical Officer to the Royal London Hospital, Moorfields, E.C.

WINDER, WALTER ESSEX, M.D., F.R.C.P., Lecturer on Pharmacology and Therapeutics at the Middlesex Hospital Medical School.

Marriages.

ALEXANDER—WOODWARD.—On May 3rd, at St. Clement Danes, James Whitelaw Alexander, M.B.C.P., L.F.P.S., The Lodge, Armley. Leeds, second son of the late Thomas Alexander, M.D., F.F.P.S.Gelas., to Laura Woodward, niece and adopted daughter of the late James and Margaret Alexander, Grove

daughter of the late James and Margaret Alexander, Grove House, Bipon.

KILDARL—WILLOCK.—On May 4th, at St. Andrew's Church, Fulham, Edward Hulse Willock, M.B.C.S., L.B.C.P., second son of the late Edward Hulse Willock, 3rd Bengal Cavalry, to Eliza Frances Iris, eldest daughter of the late William Sobieski Kildahl, of Dublin.

LEVICE—CASTLEDINE.—On April 27th, at Kirkella, Harry Driffield Levick, M.B., B.Sc., F.B.C.S., of 132, St. Paul's Terrace, Middlesbrough, son of Henry Levick, of Thranstone, to Harrlett Minnie Castledine, M.B., B.Sc., daughter of the late Henry Castledine, of Gloucester Gate, Regent's Park, London.

Deaths.

EUSTACE,—On May 4th, at his residence, Elmhurst, Glasnevin, Dublin, John Eustace, M.D., J.P., aged 73.

PAGET.—May 7th, at Litchfield Lodge, Hereford, Clara, widow of Sir George E. Paget, K.C.B., M.D., F.R.S., of Cambridge,

Sir George E. Paget, R.C.B., M.D., T.R.C., aged 73.

PINE. On May 4th, at Royston, Herts, Sarah Ellen, widow of the late Richard Pyne, M.R.C.S., J.P., aged 89.

REYNALDS.—George Frederick Reynalds, M.R.C.S., L.R.C.P., of 4.

Normanville, Church Road, Teddington, almost suddenly, at Taquah, West Africa, on Wednesday, February 15th, aged 30, from blackwater fever.

Scott's Emulsion

In Diabetes, Gout, Rheumatism and Bright's Disease.

Should the physician desire cod-liver oil to be a part of the treatment of any of the above diseases, and should he prefer an emulsion of this oil, he will undoubtedly be pleased to know that the sweet taste of Scott's Emulsion is due to GLYCERINE, and not to sugar. We do not use sugar to make our preparation palatable. There is consequently no danger from uricacidæmia or glycosuria.

The value of glycerine in Scott's Emulsion cannot be too strongly emphasized. Nature makes glycerine in the digestion of fats, showing the need of it. The glycerine also facilitates the absorption of the oil, thus further promoting the final object toward which the minute and permanent division of the oil is the first step.

Add to this combination of cod-liver oil and glycerine, the hypophosphites of lime and soda, and you certainly have a preparation that merits at least comparative tests.

BENGER'S

GOLD MEDAL AWARDED

Health Exhibition, London.

FOR INFANTS, INVALIDS, FOOD.

This delicious highly nutritive and most easily digested Food is specially prepared for Infants, and for those whose digestive powers have been weakened by illness or age.

The following letter addressed to F. B. BENGER & CO., Ltd., is published by special permission of the Russian Court.

"Balmoral Castle,

"Scotland, 25th Sept., 1896.

"Sirs,—Please forward to Balmoral Castle one dozen 2/6 Tins of BENGER'S FOOD for H.I.M. THE EMPRESS OF RUSSIA, addressed to Miss Coster. We have received the box ordered from Peterhoff.

"Yours truly, F. COSTER."

The Lancet describes it as "Mr. Benger's admirable preparation."

THE MEDICAL PRESS says:—"Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick."

The British Medical Journal says:—"Benger's Food has by its excellence established a reputation of its own."

The Illustrated Medical News says:—" Infants do remarkably well on it. There is certainly a great future before it."

A Government Medical Officer writes:—"I began using your Food when my son was only a fortnight old, and now (five months) he is as fine a boy as you could wish to see."

From an eminent Surgeon:—" After a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed."

A Lady writes:—"Really I consider that, humanly speaking, Benger's Food entirely saved baby's life. I had tried four other well-known Foods, but he could digest nothing until we began the 'Benger.' He is now rosy and fattening rapidly."

BENGER'S FOOD is sold in Tins at 1/6, 2/6, and 5/-, by Chemists, &c., everywhere.

Wholesale of all Wholesale Houses and Shippers, or of the Manufacturers,

F. B. BENGER & CO., Ltd., Otter Works, Manchester.

Bynin

Perfection of Liquid Extract of Malt

Although Ciquid, BYNIN possesses the same diastasic power as the ordinary thick Extract.

BYNIN mixes readily with milk, helping Being Ciquid, complete digestion, and preventing the formation of large clots of casein.

BYNIN is far more pleasant to take, more As Ciquid, easily mixed with other food, and more quickly assimilated than the thick Extract.

Bynin is a boon to Rursing Mothers, replacing Alcoholic drinks.

DIASTASIC ACTIVITY.—"We find that at a temperature of 100°F. one ounce will digest perfectly one pound of starch. This is a most satisfactory result, and, coupled with the fluidity and pleasant flavour, renders this preparation a most valuable one."—The Lancet.

Allen & Hanburys Ltd., Plough Court, London.

REPORT

On an Exact Bacteriological Investigation made to ascertain the Value of

Sanitas" Fluid, "Sanitas" Oil, & "Sanitas" Emulsion

As DISINFECTANTS for GENERAL USE.

By C. G. MOOR, M.A. (Cantab.), F.I.C., F.C.S.,

Member of the Society of Public Analysts, Joint Author of "Applied Bacteriology," &c., &c.

4 DANES INN, W.C., LONDON, July 2nd, 1898.

C. T. KINGZETT, Esq., F.I.C., F.C.S.,

THE "SANITAS" COMPANY, LIMITED,

BETHNAL GREEN, LONDON, E.

BETHNAL GREEN, LONDON, E.

DEAR SIR,

I beg to present you my report on the experimental investigations I have conducted on the preparations manufactured by your firm, named "Sanitas" Oil, "Sanitas" Emulsion, and "Sanitas "Fluid.

The experiments were made to ascertain and establish, if possible, on a scientific basis, the efficiency of these preparations, and their suitability for the purposes for which they are designed as indicated by your publications and labels giving directions for use.

The experiments instituted for this purpose were as follows:

(a) In the case of the preparations above mentioned, various disease organisms—namely, those of Anthrax, Cholera, Diphtheria, Staphylococcus Pyogenes Aureus and Typhoid were brought into contact with the disinfectant for a given time and in a manner detailed below, and means were taken to ascertain whether the disinfectant employed was sufficiently powerful to determine the death of the organism in a given time.

whether the disinfectant employed was sufficiently powerful to determine the death of the organism in a given time.

(b) A second series of experiments was undertaken to ascertain the effect when similar cultures were exposed to different strengths of these disinfectants for a standard time.

(c) Experiments were also made to ascertain the effect on ordinary air, as regards the removal or extermination of organisms suspended in it, by spraying with "Sanitas" Fluid.

"Sanitas" Fluid.
(b) In the case of "Sanitas" Oil, I have experimented as to the action of the vapour given off at a temperature not exceeding that of the human body.
(c) Finally, I have tried some experiments to ascertain the action of "Sanitas" Oil and "Sanitas" Fluid on the Bacillus of

TABLE 1.

EXPERIMENTS WITH "SANITAS" OIL.

Silk threads infected with cultures of the following organisms were exposed in "SANITAS" OIL for the times shown below and then incubated in broth. Growth is shown by a + sign, no growth by a

Diphtheria	_	_	_
8. P. Aureus	+	_	_
Typhoid	_	-	_

Controls all grew well.

Controls all grew well.

I next proceeded to ascertain the strengths of these disinfectants required to ensure the death of the above-named bacteria in a given time—and in the following experiments the time of exposure of the bacteria to the action of the disinfectant was in all cases ten minutes. In these experiments I used the method of shaking together an actively growing broth culture of the organism to be tested, with such a quantity of disinfectant that the resulting mixture contained the strength of disinfectant specified in the tables below; the exact details of the method of experiment are described in Pearmain & Moor's Applied Bacteriology, 2nd Edition, pages 377-382. (Ballière, Tindall, and Cox).

TARIX S

"SANITAS OIL.—As the Oil is not readily miscible with water the "Sanitas" Emulsion, which contains 45 per cent. of "Sanitas" Oil, was employed. Ten minutes' exposure.

Anthrax and S. P. Aureus were also both destroyed by the 50 °/o. mixture in ten minuces' exposure. Controls all grew well

(5). I have made several experiments as to the destruction of bacteria floating in the air of a room by spraying the air with "Sanitas" Oil, and with "Sanitas" Fluid—testing the air by means of Hesse's tube.

Hesse's tube.

The removal of bacteria from air by spraying will, doubtless, depend very greatly on the mechanical action of the particles of spray, because, as is well known, bacteria are very largely removed from air by a shower of rain, therefore, too much importance must not be attached

as as wen known, bacteria are very largely removed from air by a shower of rain, therefore, too much importance must not be attached to such experiments.

Taking, however, the mean of several experiments, whereas the air of the room contained a considerable number of bacteria before spraying, the numbers were reduced, after spraying, to under five per cent. of those previously found.

(6) "Sanitas" Fluid does not give off much vapour at ordinary temperatures; but, Sanitas" Oil, on the other hand, is sensibly volatile at room temperature, and I have tested the action of the vapour given off by "Sanitas" Oil, at blood-heat on bacteria similar to those used in the broth and thread experiments.

Some of the growth from agar tubes was smeared on filter-paper and suspended in a wide-mouthed jar containing a little "Sanitas" Oil. The whole was placed in the incubator (37° C.), and, after an hour, cultures were made on to nutrient media. The result was that only the two most resistant organisms—namely, Anthrax and Staphylolocus Pyogenes aureus—had survived, while Cholera, Diphtheria, and Typhoid failed to grow.

(7) Having a culture of Bubonic Plague brought by a student from

(7). Having a culture of Bubonic Plague brought by a student from Hong-Kong. I tried the effect of "Sanitas" Fluid and "Sanitas" Oil on it. The bacillus was killed in each case by a ten minutes' exposure to a strength of 33 per cent. of each disinfectant—the only strength tested.

tested.

In conclusion, I regard the results of my investigation as affording ample evidence that the "Sanitas" preparations are thoroughly reliable, when employed in the strengths and for the purposes specified in the directions issued by the proprietors, while their non-poisonous nature and pleasant character render them applicable in many instances where such substances as carbolic acid or mercurial chloride would be inadmissible or dangerous

MALFORMATIONS OF THE KIDNEY AND DISPLACEMENTS WITHOUT MOBILITY.

WITH ILLUSTRATIVE CASES AND SPECIMENS.

By DAVID NEWMAN, M.D., F.F.P.S., Surgeon, Royal Infirmary, Glasgow.

(Continued from page 480).

II. VARIATIONS IN FORM AND SIZE.

1. General Variations in Form-Lobulation. — Slight changes in shape from the typical normal kidney are by no means uncommon, and in more marked instances the organ may be elongated so as to become sausage-shaped, or it may be increased in thickness and globular in form, resembling the shape of the kidney in the forms. The form cong the kidney of the kidney in the fœtus. In a few cases the kidney has been found to assume the discoid shape. These alterations from what we may assume as the normal type, are often unassociated with any other anomaly; but when an abnormal condition exists, such as malposition of the kidney, atypical distribution of vessels, or malformations of other genito-urinary organs, then lobulation of the kidney is more frequent in occurrence, and more marked in degree. In etus and in young children slight lobulation is seen, but usually after the first year of life the lobules become fused, and are no longer apparent, unless in exceptional cases. In some of these the separation of the lobules may not be very distinct on the surface of the organ, but if a vertical section of it be made the original lobulated condition of the gland is seen. The persistence of this fœtal condition is generally more marked at the anterior than at the posterior aspect of the kidney. A section of the kidney shows the medullary substance arranged in wedges, which form the pyramids, separated from one another by the columns of Bertini. These pyramids correspond to the embryonic lobules of the kidney, though several

lobules may fuse together in one pyramid.

2. Hypertrophy of one kidney—Hypertrophy of one kidney is not often met with independently of some condition which has produced a functional weakness

of its fellow.

Hypertrophy of both kidneys is, however, often seen in cases of diabetes insipidus, and perhaps also

in diabetes mellitus.

Enlargement of one kidney only may, however, occur independently of any functional inactivity or structural defect of its neighbour. The kidney may go on increasing in size beyond the normal limit, just as we may have excess of growth in one limb, or undue growth of individual fingers or toes, of the tongue, the larynx, or the lower jaw.

CASE 13.—Simple hypertrophy of the left kidney only, right kidney normal in size and appearance.

At a post-mortem examination upon a man, æt. 36, who died from fracture of the skull, I found the

right kidney to be normal in weight, $6\frac{1}{2}$ ounces, while the left weighed $10\frac{3}{4}$ ounces. The man was of average height, and weighed $11\frac{1}{4}$ stones. Both kidneys, on microscopic examination, were found to be typically healthy, with the exception of the histo-logical elements of the left kidney which were uniformly enlarged, as has been observed in cases of

compensatory hypertrophy.

(3) Fusion of two kidneys.—(a) Horse-shoe kidney; (b) sigmoid kidney; (c) disc-shaped kidney. The amount of fusion that takes place between two kidneys varies greatly. We may have the two organs united together across the vertebræ, at their lower extremities, by a narrow, thin, and flat isthmus, which may be formed of connective tissue only, as illustrated in Fig. 12, or the union may be made up of kidney parenchyma; these are the lowest grades of coalescence, and from these we meet with all degrees of fusion antil we reach a condition where the two or rusion antil we reach a condition where the two kidneys become completely incorporated in one another, so as to form either one disc-shaped organ (Fig. 17), generally situated in the middle line, or an elongated body on one side of the spine—the sigmoid kidney (Fig. 16); but in fused kidney, however unshapely the renal mass may be; the renal form may be entirely lost on both sides; the hilum may be absent; the polyic may be distorted, and the blood. absent; the pelvis may be distorted; and the blood-vessels most irregular in their distribution; there is still one feature in all its varying forms, namely, that they all possess evidence of two ureters, and not

one only, as in true examples of single kidney.

We will first consider the lower degrees of fusion, and afterwards will give instances where more complete incorporation of the two organs has taken

place.

(a) Horse-shoe kidney is the most common form of fusion. The two organs are joined together at their lower ends, sometimes by a simple band of tissue, as, for example, in Figs. 12 and 13. In other instances the union is more complete, while the renal form of the two lateral segments may not be retained, as in Fig. 14. Or, again, as in Fig. 15, not only may the renal outline be considerably distorted, but there may also be marked lobulation, as well as anomalous distribution of the bloodvessels, or deformity of the pelves and ureters.

CASE 14.—Horse-shoe kidney, united by an isthmus of fibrous tissue at the level of the bifurcation of the

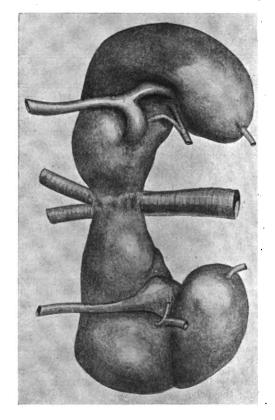

aorta. Renal form well retained. (a)

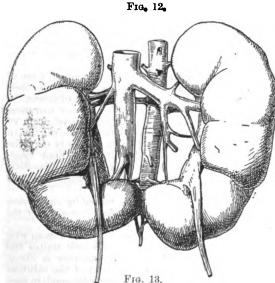

Horse-shoe kidney from the body of a man who died of pneumonia; the isthmus which unites the lower ends of both kidneys to one another is about 1 inch broad, and is situated in front of the bifurcation of the aorta; that vessel is unusually small in size. The right ureter arises from the pelvis by two distinct channels, and passes downwards in a groove, which is more distinctly marked than the corresponding one on the left side. The left ureter occupies a similar position, but the pelvis from which it arises is almost normal in form.

The blood supply is by five arteries, which pass off directly from the aorta. Two arteries supply the right segment, while the left is supplied by three. Considering the anomalous distribution, the arterial

(a) Glasgow Royal Infirmary Museum, Series VII., No. 3.

supply is wonderfully symmetrical. On both sides an artery passes directly to the upper and convex aspect of the kidney, while the other arteries pass

into the kidney at the hilum. In the specimen the veins have not been preserved (Fig. 12).

Drs. Sutherland and Edington published in the Glasgow Medical Journal, Vol. XLIX., page 89, an example of horse-shoe kidney. where the departure from the normal is even less than in the case just referred to. In their case the two kidneys are united by an isthmus of renal tissue which measures 1.3 cm. vertically, and 3 mm. antero-posteriorly. Poth kidneys, however, are distinctly lobulated (Fig. 13).

CASE 15 .- Horse-shoe kidney with lobulation and

complete fusion of both kidneys, malformation of pelves, and anomalous distribution of bloodvessels.

Both kidneys retain to some extent their renal form, and are united at their lower ends by a distinct lobule, which is marked off by two deep grooves, on the right side the pelvis is not greatly malformed, but on the left it is abnormally small, and is separated into two distinct branches, one passing to the upper, the other to the lower part of the organ. The right segment receives one artery, while the left is supplied by two, one entering at the hilum, the other close to the upper end of the kidney. Both renal veins pass out at the hilum (Fig. 14).

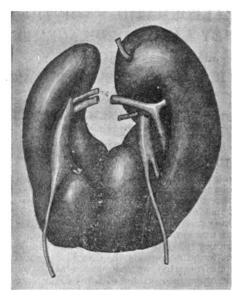

Fig. 14.

Case 16.—Horse-shoe kidney with complete incorporation of the two organs. Lobulation of both segments, the ureters deformed, and anomalous distribution of the bloodvessels. (a)

The two kidneys are completely united at their lower ends, and the whole renal mass although lobulated is, roughly speaking, uniform in diameter, and in this respect contrasts with the previous specimens.

When removed from the body the mass weighed 15½ ozs. The arteries, which are small in size, sprang direct from the aorta, and the veins passed to the vena cava direct. On the right side three arteries enter the kidney on its upper aspect, while the left segment is supplied by an artery which enters the deformed hilum on the right side. Three venous trunks unite to form one vein before the blood is emptied into the vena cava. while on the left side one vein only leaves the kidney from the hilum. On the right side the pelvis is divided into three distinct branches, which unite, at the lower limit of the horse-shoe, to form the right ureter. On the left side the pelvis is also segmented into three parts, forming roughly with the ureter the appearance of a St. Andrew's cross. The ureter passes downwards in a deep groove on the anterior aspect of the horse-shoe.

As a rule the horse-shoe kidney rests on both sides of the spinal column, but lower down than normal, the isthmus generally crossing the vertebral column about the level of the bifurcation of the aorta. The band of union is almost always at the lower extremity, so that the concavity of the horse-shoe presents upwards. Cases, however, have been recorded where the union was found to be at the

⁽a) Royal Infirmary Museum, Series VII., No. 4.

upper, in place of the lower, ends of the organ. It has been already shown that the bond of union between the two segments may be slight, or may be very intimate. In the former, the blood-vessels, pelves, and ureters seldom depart much from the normal in their number or distribution; but when the binding of the two organs is very complete, the auxiliary structures also are markedly anomalous. This circumstance may raise the question whether or not the anomalous distribution of vessels may be regarded as a cause of the malformation of the kidney. The pelvis may be divided into several separate cavities, which unite to form the ureter some distance from the hilum. Monquiot (a) publishes a case where a kidney was placed transversely across the lumbar vertebræ, and had four pelves, four ureters, and as many arteries and veins. Whatever the other deformities may be the ureters seldom pass

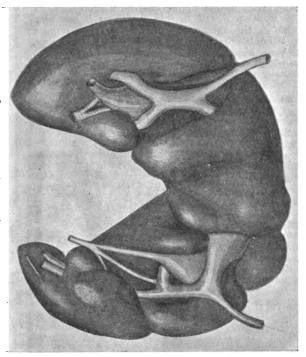

Fig. 15.

behind the renal mass. Durham (b), however, describes a case in which the ureters passed behind the organ. The united mass weighed 13½ ozs., and was formed by the union of the lower extremities. The structure

of the kidney is described as normal.

Sutherland and Edington describe an interesting example of horse-shoe kidney, in a male child, where there was a pyonephrosis limited to the left segment. On this side the pelvis was greatly dilated, and there were cavities representing dil-ted calices, which largely replaced the renal tissue and still contained remains of pus. The left half of the isthmus showed a similar lesion; the right side of the specimen and the corresponding portion of the isthmus were normal.

Morris (c) describes and illustrates a most unusual form of fused kidney, and one with which I am not familiar. The two kidneys lie together, as if the hilum of one kidney was placed against the outer convex aspect of the other. The following is his de-

scription of the specimen:—
"The two kidneys formed an irregularly shaped

(a) "Journal des Savants," 1878, Mai 16me. (b) Guy's Hospital Reports," 1860, p. 407. (c) "Surgical Diseases of the Kidney," 1885, p. 96.

mass which weighed 13 ozs., and was lying on the front of the promontory of the sacrum. It was not an ordinary horseshoe, for the vessels and ureters were arranged most unusually. The central part of the mass was fissured by a sulcus, in which the ureter for the left kidney coursed downwards and the vein for the same upwards, passing into the vena cava just above the junction of the two iliacs. In the right half of the mass the ureters and vessels, instead of being situated centrally, were on its outer side; the ureter being in front of the vessels as in the left, and as is usual in fused kidneys. The arterial supply in each consisted of two or three arteries for each half of the mass about the size of radials derived from the common iliac arteries, and entered the lower part of each kidney. The suprarenal capsules were in their normal positions. The renal substance to the naked eye was healthy."

(b) Sigmoid kidney. Sigmoid kidney is an end to end fusion of the two organs. In this anomaly both kidneys occupy one side of the body only, but while the condition is unilateral it cannot be properly included under the term "single kidney."

The following specimen from the Museum of the Royal Hospital for Sick Children, given to me by Dr. Lewis R. Sutherland, illustrates very beautifully a typical sigmoid-kidney. I may quote his description of it in the Glasgow Medical Journal for February, 1898, p. 95:—

"Fusion of kidneys in a female child. The fused mass, which measures 11.5 cm. in length, presents an elongated reniform outline, and is possibly formed by the superposition of one kidney on the other, as represented in the accompanying sketch (Fig. 16).

"The anterior surface of the mass is irregularly

lobulated; the posterior surface is smooth. There are two distinct pelves, one above the other, each in its own hilum. The upper hilum presents antero-

internally; the lower anteriorly.

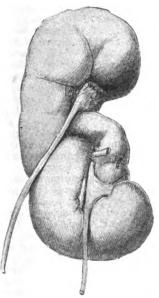

Fig. 16.

"The ureters, which are of normal dimensions pass downwards and outwards from the corresponding pelves, and lie in grooves on the anterior surface of the mass. The upper entered at the right, the lower at the left angle of the trigone. The bladder was normal. vascular relations were not fully determined.

"The suprarenal bodies were normally disposed. An examination of the generative organs was not made. Microscopic examination of the fused mass shows normal renal tissue.

"The specimen was removed post-mortem from a girl about 7 years of age. The The

mass occupied the right renal region, and was distinctly palpable in life (G.H.E.). There was no trace of renal tissue found on the left side.

"Note.—The appearances suggest an incomplete union of two kidneys—the smaller (lower part of the mass) representing the left; the larger (upper part) the normally placed right kidney.

"From the relations of the lower ureter and pelvis inversion of the left kidney may possibly be inferred, as well as coalescence with the anterior surface of the inferior extremity of the right kidney. (Royal Hospital for Sick Children.)

Almost precisely similar specimens are described by Dr. G. Broesike, of Berlin (a), and by Dr. A.

Birmingham (b).

Sigmoid kidney may be regarded as intermediate between horse-shoe kidney and disc-shaped kidney. The first-mentioned fusion is very complete, while in the latter only the lower extremities of the organs are united. They differ also in the circumstance that the disc-shaped kidney and the horse-shoe kidney are most frequently placed in the middle line, while in sigmoid kidney one kidney is transferred to the opposite side, where it is joined to the lower or inner part of the opposite organ. Probably sigmoid kidney is the rarest form of fusion.

Disc shaped kidney is (c) Disc-shaped kidney. applied to those instances where incorporation of the two organs is very complete, as for example in the following cases—an illustration of which has been

given to me by Drs. Sutherland and Edington:

"Fusion of kidneys in a male infant Hypospadias.
Umbilical hernia sac. The kidneys form a mass of approximately reniform outline, measuring 6.5 cm. vertically, 3 cm. laterally, and 2.5 cm. antero-posteriorily. The anterior surface shows distinct lobulation; the posterior surface is smooth (Fig. 17).

"The hilum faces anteriorly or antero-internally, a small amount of renal substance being situated towards the middle line behind. Emerging from the hilum are two distinct simple pelves, one above the other. This is corroborated on making a section of the mass. The lower ureter passes to the right side of the trigone, and is crossed anteriorly by the upper ureter on its course to the left side of the trigone.

There are three sets of renal arteries: (1) an upper, entering the upper end of the hilum; (2) a lower, entering the lower end of the hilum; and (3) a third vessel supplying the intermediate parts. Branches 1 and 3 srise from the lateral aspect of the aorta, one above the other at the crossing of the renal vein. Branch 2 arises from the anterior aspect of the aorta to the right and below the origin of the inferior mesenteric artery. The renal vein is formed mainly by three tributaries emerging from the upper and middle portions of the hilum. It crosses the aorta in the normal situation of the left renal vein. There is entire absence of corresponding renal vessels on the right side.

'The specimen shows further the obliterated hypogastric arteries, and a portion of persisting urachus likewise obliterated. The bladder is normal (shown turned downwards and forwards in the figure).

"The specimen was removed post mortem from a

male infant, æt, 2 months, who died of acute broncho-

pneumonia.

"The 'fused kidney' occupies the left side. There was entire absence of kidney on the right side. The right suprarenal body, however, was present, as shown in preparation, but markedly flattened out on the under surface of the diaphragm. The left suprarenal body occupies its normal position. Both suprarenal bodies were supplied by vessels arising directly from the aorta, the left receiving in addition two twigs from the highest renal artery. The left suprarenal vein emptied into the left renal vein, the right suprarenal vein directly into the inferior vena Microscopic examination shows a normal structure. The vasa deferentia, vesiculæ seminales, and testes were normal. There was fairly well-marked hypospadias. There was also a small marked hypospadias. umbilical hernia sac.

"Note.—The relations of the ureters to one

(a) Virchow's Archiv., November, 1894.
(b) "Dublin Journal of Medical Science, Vol. XC., p. 47.

another, and the origin of the lowest renal artery, are compatible with the possibility of the lower half of the mass, having occupied a position to the right of the median line. (Royal Hospital for Sick Children.)'

C. VARIATIONS IN THE PELVIS, URETERS, AND BLOODVESSELS.

Malformation of the pelvis and ureters is fairly common, but these are generally of little importance.

The pelvis and upper two inches of the ureter are very frequently abnormal in cases of misplaced or malformed kidney, but even where the kidney is normal in position and in form the ureters may be deformed. These abnormalities have been already fully illustrated in the foregoing cases, in some of which the pelvis has been seen to be double or in several divisions, each of which may have a separate connection with the ureter.

The ureter may be double only for a short distance in its upper part, but in rare instances it has been found so throughout its whole course. We have seen a double ureter extending to within two inches, and cases have been described where it has extended

to within one inch of the bladder.

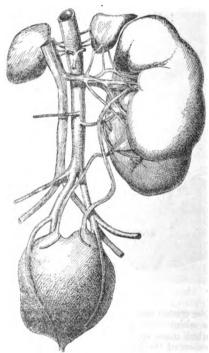

Fig. 17.

Mr. John Wood (a) describes such a case. He says: "That in a male subject four ureters were discovered emerging from the hilum of each kidney. they united after proceeding about four inches towards the bladder forming a pelvis from which sprang the ureter proper. On section of one kidney the hilum was found occupied by a quantity of fat and connective tissue, embedded in which the ureters could be traced to the infundibula communicating with the calices and pyramids; thus there was no pelvis within the hilum, but the calices united to form infundibula of which these ureters seemed to form a continuation, and they became united in the pelvis some distance from the kidney.

Cases also have been described by Thomson, Coen,

Richmond, Longé, Féré, Josso. It may be safely said that no abdominal arteries

(a) "Transactions" of the Pathological Society, London, Vol. VII, p. 261.

are more irregular in their distribution than are those which supply the kidneys. They may vary in number, in their source of origin, or in the mode in which they enter the kidney. Cases have been recorded where both renal arteries have originated from a common stem arising from the front of the aorta, or the renal blood supply may be augmented by branches from the internal, external, or common iliacs, from the suprarenal artery, from the hepatic artery, or from the middle sacral.

The mode of entrance of the arteries also varies. They may pierce the kidney at the bilum, or may enter at any part of its surface, but most commonly abnormal vessels are found at the upper extremity of the organ. Again, the renal arteries may give off branches to the diaphragm, to the ascending colon, to the liver, or to the pancreas.

These irregularities in source, number, and distribution are well known, and have been fully described by Professor M'Alister. (a)

Professor Joseph Coats showed a specimen at the Glasgow Pathological and Clinical Society, (b) which has some bearing upon the subject we are now considering. The specimen was one of hydronephrosis, where constriction of the ureter was caused by the pressure of an abnormal renal artery.

Professor Coats says, "The kidney has been supplied by two principal arteries. This artery has four branches, three of which pass into the kidney along the anterior border of the pelvis, whilst the fourth has passed rather downwards and backwards. In its passage this artery has encountered the ureter, and has crossed the latter shortly before its insertion into the apex of the pelvis. There is a deep groove produced by the artery, beneath which the ureter passes. The two rounded bulgings which here conceal the parts are, respectively, the dilated first part of the ureter and the apex of the pelvis. The dilated piece of ureter could be brought out by pulling on the ureter, and it was then seen that, at the place where the artery crossed the ureter, the wall of the latter was greatly thinned, the muscular coat being apparently destroyed."

We placed in the museum of the Royal Infirmary a peculiar abnormality of the kidney associated with a malformation of one ureter. The left kidney is about two inches longer than normal, and is divided by a deep groove into two distinct parts, the upper the larger, and the lower the smaller part, are each provided with a distinct pelvis and ureter, but the ureters join about two inches from the lower border of the organ.

A SERIES OF CASES OF ARTHROTOMY FOR THE RELIEF OF PAIN, REMOVAL OF SYNOVIAL FRINGES, LOOSE BODIES, AND FIBRO-CARTILAGES.

By C. B. LOCKWOOD, F.R.C.S.,

Assistant Surgeon and Lecturer on Descriptive and Surgical Anatomy, St. Bartholomew's Hospital.

THE first part of Mr. Lockwood's communication referred to four cases in which the wrist joint had been opened for the relief of pain. Two of these occurred in women, and were possibly pyæmic. joint was opened by longitudinal incision betwixt the extensor tendons, and was drained for some days, after which the wound completely healed. The The relief from pain was immediate and permanent. The

(a) "Journal of Anatomy and Physiology," Vol. XVII., p. 250. (b) "Transactions," Vol. III., p. 277.

third case occurred in a man and was proved by histological examination to be tuberculous. It was treated in a manner similar to the two former cases. Pain was immediately and per-manently relieved, and the disease was arrested. The fourth case also occurred in a woman. The inferior radio-ulnar articulation was inflamed, and had been for four years, and was the seat of extreme pain. It was opened by dorsal incision, and as the cartilage covering of the lower end of the ulnar was eroded and the bone inflamed, the head was removed. The incision was closed without drainage, pain ceased, and the ultimate recovery was perfect.

It was pointed out that in all these cases the operation was performed for the relief of pain. Mr. Lockwood had often performed arthrotomy in cases of acute septic arthritis in which pain had been present. Obviously, under these circumstances, the operation was not performed for the relief of pain but to give exit to septic or purulent fluid.

Arthrotomy for the removal of inflamed and elongated synovial fringes was next referred to. The case of a married woman was described at length. For six years she had had repeated attacks of synovitis, latterly the swelling and inflammation of the knee-joint had become almost continual. The symptoms were very like those which are caused by the presence of a loose body within the joint. None could be detected, and the joint was opened. The absence of a loose body was confirmed, but the whole of the synovial fringes of the joint were observed to be exceedingly long and inflamed. It seemed likely that some of them may have got nipped betwixt the articular surfaces. They were all removed. For this purpose the ligamentum patellæ was divided. A speedy recovery ensued. Nine months after the operation she said that the knee was better than it had been for years. She was able to walk about and perform her household duties. The movements of the joint were good and painless. It contained no fluid. Mr. Lockwood thought the membrane was still a little swollen. In connection with this case, the best manner of opening the knee-joint for the total removal of fringes was discussed. Another case of a similar character was likewise described.

Next some cases of arthrotomy in chronic osteoarthritis were described. These were undertaken because the chondrifical and ossified synovial fringes got betwixt the articular surfaces either by having become detached or because they had very long pedicles. One of these patients was in her 70th year. Nevertheless, three weeks after four loose bodies had been removed from the joint she was walking about. In a second case, in addition to pedunculated cartilaginous fringes a pedunculated fatty growth of the synovial membrane was taken away. In yet another case of osteo-arthritis pedunculated fringe was removed. The joint ceased to lock, but the operation was followed by a certain degree of stiffness due to the progress of the osteo-arthritis. The avoidance of this complication avoidance of this complication was discussed. Finally cases of excision of the internal semilunar fibro-cartilage were mentioned. One was described in which the history four years after the operation showed that the result had been perfect. In a second case of removal of the internal semilunar fibro-cartilage the history was brought down to three years after the operation. With the exception of the scar the knee-joint was normal. The patient led a most active life and considered the joint as good as the other, quite perfect in spite of the absence of the fibro-cartilage. The third case was peculiar, having occurred in a woman. In this, again, the removal of the fibro-cartilage, whilst curing the locking of the joint, was attended with no other appreciable effect.

GENERAL HEALTH AS A FACTOR IN SKIN DISEASE. (a)

By MORGAN DOCKRELL, M.D.

In selecting a subject for my Presidential Address I was influenced by the desire to point out the importance that perfect harmony should exist between those practising general medicine, and those confining their atten-tion to the special branches of medicine. And although I have on other occasions, and in other places, emphasised the fact that the interests of general and special practitioners, from a merely commercial view, are identical, the present seemed to me to be a fitting occasion to consider the identity of these same interests from that higher and more scientific plane where, free from personalities, pettiness, and all uncharitableness, we can look on disease defacing, as it does, the most perfect work of the great Artificer, and, looking, remember that no matter how local such disease happens to be, it exercises an effect on the whole economy, producing general disturbance, which reacts on the local trouble, thus indissolubly binding together cause and effect, necessitating a knowledge of systemic medicine with that of local treatment, and making the general practitioner a necessity to the special practitioner, and the specialist of service to the general practitioner.

My object then, gentlemen, this evening is to indicate

clearly, and I hope convincingly, that it is equally impossible, for the specialist to practice his speciality successfully without treatment of the general health, as it is for the general practitioner of medicine to ignore the treatment of local disease on the ground either that the patient will grow out of it, or that by the perseverance of systemic medicine alone the local trouble

will be cured.

And this takes me more immediately to the subject of my address to you—namely, "General Health as a Factor in Skin Disease." To some this title may appear almost a paradox, understanding as they rightly do that health is the maintenance in equilibrium of all the parts of an organised being so that the natural functions of all the organs may be performed freely and properly, and, therefore, any departure of the cutaneous envelope from the normal, either in its secretion, or thickness, or appearance constitutes a breach of this definition, and is, of necessity, an interference with general health. Unfortunately, however, this is not the case, and so one finds a large number of those practising dermatology ignoring the treatment of certain skin diseases by other than local means, or at the most skin diseases by other than local means, or at the most prescribing certain empirical remedies internally, which have a reputation for curing particular diseases, without taking the trouble to ascertain the conditions of general health which have led up to them. And although it may be urged that such a distinguished authority as the late Dr. Tilbury Fox was in the habit of dividing diseases of the skin for the purpose of therapeutics into those, "1, which are purely local, 2, which require mainly local remedies, but demand the use of such as are general as auxiliaries to cure: 3. where use of such as are general as auxiliaries to cure; 3, where general are the most important, local measures being employed as secondary ands to cure." I believe if he were living in these days he would recognise the importance of general treatment in all cutaneous diseases.

In the present day we have Kaposi stating "that both pathological histology and experiment have proved most cutaneous diseases to be purely local diseases which days local in the tienness of the chiral and the local diseases which develop in the tissues of the skin, and which in a measure can be at any time produced at will in one who is in perfect health."

Jameson, on the other hand, says: "All measures which will cure our patients are not only permissible but to be recommended, and thus a combined external and internal treatment is best for all." With this latter opinion I readily agree, and I cannot help thinking that this, so to speak, impressionist method of simply prescribing for the condition that strikes the eye, is largely due to the overcrowding of our out-patient

(6) Abstract of Presidential Address, delivered to the West Kent Medico-Chirurgical Society, May 5th 1899.

departments which prohibits us from giving that attention to general health which is so essential to skilful treatment, and especially is this the case with those who have not had the only true training for specialism,

namely, some years in general practice.

For greater convenience I will deal with my subject under two heads, namely: 1. Conditions of general health requiring treatment first in those diseases where internal treatment is said to be unnecessary. 2. Quite apart from certain orthodox internal remedies advised for

particular diseases.

1. Those diseases where internal treatment is said to be

unnecessary.

Now, gentlemen, in the treatment of diseases of the skin it is always well to bear in mind a condition which, for want of a better term, may be called the "tone of the skin," namely, where the functions are healthy and performed with vigour, that is where the skin is well strong or in due tension, not over strung. When there strung or in due tension, not over strung. When there is any departure from this, the general health is at fault, and so one finds certain diseases of occupation taking and so one inus certain diseases of occupants which place, as, for example, the form of eczema, which affects barmaids, washerwomen, hairdressers, and others, who have carried on their calling for years without any trouble till from other causes their general health becomes impaired. Surely there is some-thing more than mere local irritation to account for the square patch of eczema in the palm of the left hand of the bricklayer where the brick comes in contact with it, and those patches sharply limited in the right hand to the parts which grasp the trowel. And if not, how is it that he never gets better till his general health is attended to, and how is it that as the health improves, the local disease quickly responds to treatment. There is one factor, and one only, in all these conditions which enables the skin to resist the irritation of occupation,

and that is general health.

You are all familiar with "Warts" (verruca vulgaris), and, I trust, but few of you hold Kaposi's view that they and, I trust, surface of you do, you can readily satisfy yourselves as to its fallacy by watching how quickly children looked after by a nurse with warts on her hands contract the disease if they happen to get out of health. Warts will last for years, resisting all kinds of local treatment until the mal-assimilation and the constipation, which is so commonly present, are treated. however, sulphate of magnesia, as advised by Colrat, of Lyons, or, in some cases, thyroid extract, be given internally in combination with local treatment, the warts disappear and no recurrence takes place as so often happens

when only treated by local means.

But I can fancy some of you saying, the growth of hair out of place in woman can only require the local treatment of electrolysis. Here, again, general health must be taken into account. Amenorrhea is often present, and when treated, strong hairs cease to appear. Young unmarried women with strong sexual proclivities which remain unsatisfied, require the administration of bromides internally. Again, in married women, where through the fear of pregnancy the sexual act is not com-pletely performed, hairs develop and only cease to recur on the cause being removed. Again, young widows develop hairs, which disappear on re-marriage. And I would point out that the loss of mental balance is often so great owing to the worry or the disfigurement of constantly recurring hairs, that to prevent insanity, removal of the ovaries has been found necessary as the only way to check their continued growth.

Lest I weary you I will now pass to the second head,

2. Conditions of health requiring treatment quite apart from certain orthodox internal remedies advised for particular diseases.

Gentlemen, the treatment of skin diseases is no longer a rule of thumb, the time has gone, and well gone, when a disease coming under observation means the use of a particular drug; it is now known that although a drug may be of benefit in one disease its use is subservient to those states of general health which have led up to and predisposed the individual to the local indication apparent on the skin. Hence it is the duty of every self-respecting practitioner who wishes to practice his art in a

scientific spirit to make himself conversant with the state of health of all the organs of the body, 'o carefully inquire into the secretions, and the habits of his satient, and then, and not till then, to turn his attention to the disease of the skin complained of; above all, to remember there is no therapeutic panacea for any disease. Arsenic has its uses, but they are very limited. It has been a vastly over-rated drug, and its wholesale indiscriminate use has done an immense deal of harm in the past, and I fear in the present is still doing a certain amount.

If we take the different conditions of general health exercising a marked effect on skin diseases, I would place over-fatigue as the most important factor. In the present state of civilisation we suffer from the overfatigue of work and the over-fatigue of pleasure. The old saw that change of work was the best recreation no longer holds good. Our pleasures have become a toil, and are often harder work than our ordinary business. So, complete rest in bed will often cure an eczema or a pruvitus in a few weeks, which for months, has baffled

Then again worry exercises a marked predisposing cause in some of the diseases affecting the hair, not so much the ordinary anxieties of business as the petty annoyances of domestic infelicity, the nagging wife, the drunken husband, the sickly child, the interfering mother-in-law, all play their part in producing the neurasthenia which results in alopecia areata. Here your pilocarpin and thyroid extract internally are of no avail, unless you build up the nervous system by means of electricity, didynim, and other nerve tonics. Habits also require attending to, the matutinal pipe often indulged in travelling up to town in a smoking carriage is highly detrimental, producing, as it does, cardiac depression, just as later in the day the heavy luncheon, which is followed by brain work results in wasting of nerve tissue and indigestion, through neither the brain nor the digestive organs having the proper blood supply to carry on both processes at the same time.

Sexual Indulgence also has to be regulated, bearing in mind that what is excess in one is but moderation in another. Let me quote an example of this. In 1894 a patient consulted me for complete loss of hair and gave the following history:—As a young man, up to the age of 25, he had an excellent growth of hair, within three months of his marriage he was completely bald, and remained so till the death of his wife, which occurred four years later. Within a year he had a good head of hair, and this remained so till his second marriage five years afterwards; but six months only had elapsed when he was quite bald again, and has remained so to the present day. During his widowerhood he had connection about once in four months, while during his second marriage he did not have intercourse oftener than every two weeks.

Uric acid also has to be dealt with, not only as a pre-disposing cause when circulating in the blood, but also as an exciting cause when excreted by the skin. At the same time I do not wish to be understood for a moment as suggesting that there is any such condition as gouty eczema, any more than I believe that uric acid per se means gout. Uric acid plus something else, probably either a parasite or a neurosis, may result in a disease of the skin, so uric acid plus x results in gout. But that there is any of the varieties of eczema particularly found in gout, and thus allowing of the term of gouty eczema, I absolutely deny. If, then, uric acid in excess is present in any patient suffering from disease of the skin it must be dealt with by careful dieting, following out one of the several methods so ably supported by their dif-ferent exponents, all equally good for certain individuals, though not all equally applicable to the same individual.

In those who have had syphilis, and who suffer from diseases of the skin not of a specific nature, it is absclutely necessary to treat with anti-syphilitic remedies, as otherwise one often finds a comparatively simple disease presenting marked obstinacy.

Time has not permitted me more than briefly to state the importance of general health in a limited number of cutaneous diseases, but it is of equal importance in those

I have not mentioned; and so, gentlemen, whether we are general practitioners or specialists we each have our work to do; let us then do it to the best of our ability, recognising the good in all branches of our common profession, and above all remembering that the care of the general health is the chief factor in the treatment of disease.

Clinical Records.

TWO CASES OF RESECTION OF THE LARGE INTESTINE, WITH RECOVERY. (a)

By FREDERIC EVE, F.R.C.S.,

Surgeon to the London Hospital and to the Evelina Hospital.

Case I. was a large left scrotal hernia, strangulated for three days. Herniotomy showed that the sac contained a knuckle of the transverse colon, which was gangrenous. A glass tube was inserted into the intestine, and the latter was attached to the wound. Five weeks later the intestine forming the artificial anus was brought out of the abdomen after opening the peritoneum, resected and sutured. The intestine was returned, and the abdomen closed. Primary union and recovery without complication.

Case II. was an example of carcinoma of the descending colon, for which the writer was indebted to Dr. F. J. Smith. A woman, aged forty-seven, had suffered with pain in the abdomen, vomiting, constipation, and occasional melæna for seven months. A tumour in the left loin had been noticed for some months.

Occupying the left loin, just below the ribs, was a tumour, movable from side to side, and evidently situated in the descending colon. The constipation culminated in an attack of obstruction, during which the first operation was performed. This consisted in bringing out the tumour with several inches of healthy bowel, and fixing the bowel to the parieties. The bowel was drained by the insertion of a glass tube.

Ten days later the protruding portion of the bowel was removed, and mesenteric edges of the divided ends brought together with sutures.

After allowing an interval of a month for the inflammatory effusion around the wound to become absorbed, an incision was made around the artificial anus down to the peritoneum. The latter was not opened, but was separated from the parieties for about two inches all round the protruding bowel. The free ends of the intestines were refreshed and brought together with Lembert's sutures. The parieties were then closed over the bowel. The wound was completely healed three weeks after the operation. At the present time the patient appears perfectly well, and has suffered no inconvenience.

The writer was of opinion that in these and similar cases the bowel should be drained, even although only moderate symptoms of obstruction existed.

Although Murphy's button could be inserted very rapidly and readily, the intestines could not be completely drained, and the shock of the resection was added to the illness from which the patient was suffering.

He thought that for the large intestine, at any rate, suture was safer than the use of Murphy's button.

Case II. was published especially to draw attention to the merits of extra-peritoneal resection and suture for artificial anus as the safest method. It was introduced by the late Dr. Greig Smith.

This operation was attempted in Case I., but had to be abandoned, owing to the extreme thinness and friability of the peritnoeum. This was probably due to stretching of the membrane from the presence of a large hernial sac in its neighbourhood.

Mr. Gordon, surgeon to the Adelaide Hospital, has been appointed as Medical Officer to the Bank of Ireland vice Dr. Harrison resigned. Mr. Gordon has acted as locum tenens for some time past.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD FRIDAY, MAY 12TH, 1899.

Mr. Langton, F.R.C.S., President, in the Chair.

Dr. Hale White and Mr. Golding-Bird read a paper on

THREE ADDITIONAL CASES OF RIGHT COLOTOMY FOR CHRONIC COLI1IS.

The object in all three cases was to give the colon absolute rest.

Case I.—The patient was a lady, æt. 36, seen with Dr. A. E. Taylor. She had had membranous colitis twenty years with latterly great pain, and almost complete inability to take food. She was wasted, anæmic, and a complete invalid, unable to take any exercise. The whole colon was tender to pressure. On May 13th, 1896, the first stage of right lumbar colotomy was performed, the bowel being opened six days later. The patient did uninterruptedly well, was relieved from pain, and gained in strength. In May, 1897, the artificial anus was closed. In November, 1898, the patient said she was perfectly well, she ate ordinary food, took outdoor exercise, and was about to learn to ride a bicycle.

door exercise, and was about to learn to ride a bicycle.

Case II.—The patient was a woman, æt. 31. In
September, 1896, she began to have abdominal pain, and
soon, because of the pain, gave up taking solid food. Her
illness continued until her admission into Guy's Hospital, under Dr. Pye-Smith, in December, 1897, when she
was found to be passing membrane. She was then
very anæmic and weak, and was suffering severely. As
she became worse, in spite of all medical treatment, the
first stage of right lumbar colotomy was performed
March 3rd, 1898, the bowels being opened on March 8th.
She remained four months in the hospital, and when
she left she was in perfect health, and had remained
so up to the last time she was seen. It was proposed to
close the artificial anus this spring. The patient was
averse from hurrying, as she was so well in her present
condition.

Case III.—The patient, a man, et. 35, had been in the tropics and Egypt. Eight years ago he had bad diarrhœa with bleeding. This had continued on and off till his admission to Guy's Hospital. He had suffered much from abdominal pain. He had been treated in hospitals medically without any success. He was admitted into Guy's Hospital in November, 1898. He had continuous diarrhœa, had lost control over the bowels, was very wasted, anemic, and had the appearance of a man who had not much longer to live. As he was becoming worse, on December 31st, 1898, the first stage of a cæcotomy was performed, and the bowel was opened five days later. He gained much flesh and colour, quite lost his abdominal pain, and left the hospital at the end of February feeling well enough to work, and in May reported himself as very well. He was now of good colour, and plump.

The authors referred to their previous published case, two other English cases and the German case. They pointed out that all a priori argument was in favour of a right colotomy for chronic disease of the colon, for it secured absolute rest for that structure, and the cases now brought forward showed clearly that the colon was not necessary for the maintenance of perfect health. They recommended palliative or curative right-sided colotomy, for severe and otherwise, hopeless examples of the following diseases:—

(1) Intractable membranous colitis. (2) All forms of chronic ulceration of the colon that had resisted medical treatment, and which were obviously otherwise incurable. Most cases of very chronic dysentery were probably to be cured without colotomy. (3) Cases of idiopathic dilatation of the colon.

The colotomy must be right-sided, and colotomy was preferable to executomy, for when the latter operation was done, fluid faces escaped from the artificial anus, and this gave rise to much trouble, while further it was difficult to prevent some faces

passing on into the cclon. In the three cases of membranous colitis reported, it was interesting to observe that the formation of membrane ceased directly the bowel was stitched to the skin, and before it was opened. Its formation appeared to be reflexly inhibited, and this was of importance as pointing to a large neurotic element in the cases, a view which is supported by the fact that membranous colitis is most common in women, that all the cases operated upon have been women, and all have had a history of pelvic troubles. The authors believed that it was not necessary to wash out the bowel from the artificial to the natural anus, and they considered that more experience was needed before deciding upon the time for which the artificial anus should be left open, but it should certainly not be less than six months.

should certainly not be less than six months.

The PRESIDENT said that the authors' results seemed to show that an opening into the ascending colon would relieve this terrible condition. He himself had a case under his care at the present time in which he proposed to open the colon. He asked whether from the point of view of surgical treatment any distinction was drawn between membranous cases and those of mucous colitis; also whether there had been any difficulty in closing the opening in those cases in which it had been kept open for several months.

Dr. Hingston Fox mentioned the case of a gouty woman, at 48, under treatment for chronic colitis. She had hamorrhage from the bowel, which was attributed to hamorrhoids. In August last she took to her bed with severe attacks of hamorrhage, and frequent motions containing much mucus and pus. Enemata and local treatment caused much irritation. The symptoms ultimately subsided very rapidly after the sphincter had been forcibly stretched by Mr. Charters Symonds, and she remained well for some months, but there had recently been some return of symptoms.

Dr. NORMAN DALTON asked whether the method had ever been tried in cases of acute ulcerative colitis?

Mr. J. Charters Symonds said that in the case mentioned by Dr. Hingston Fox he had been led to dilate the sphincter because the disease appeared to be localised to the lower end of the rectum, and he mentioned another case in which there was hemorrhage from the rectum in which examination revealed nothing abnormal. In that case also the symptoms ceased after dilatation of the sphincter. He thought that right colotomy was better than left, and mentioned a case in which he regretted that he had chosen the left operation. The patient was a man, sixty years of age, who had had four attacks of hemorrhage from the bowel. There was a hectic temperature and signs of ulceration. A left inguinal colotomy was performed and the lower part of the bowel washed out. This was followed by temporary relief, but the bowel subsequently contracted and the artificial anus could not be closed. At the necropsy many nodules of new growth could be seen on the wall of the intestine, and Mr. Symonds thought that longer relief would have been given if the ascending colon had been opened instead of the descending.

Mr. W. J. Walsham asked what method was adopted for the purpose of closing the wound.

Dr. HALE WHITE, in reply, said that the intensity and not the variety of colitis was the guide as to surgical treatment. He did not know of any cases of acute ulcerative colitis which had been treated by this method.

Mr. Golding Bird, in reply, said that he had not had any difficulty in closing the wound. He used the method which had been employed by Laurie, freeing the bowel for three-quarters of an inch round and then uniting the raw surfaces by Lembert's sutures. Cases of acute ulcerative colitis were seldom recognised. He mentioned one case in which a girl who was admitted for supposed anal fissure died with symptoms of acute colitis and subacute peritonitis, and after death very extensive ulceration of the whole colon was discovered.

EMPYEMA OF THE MAXILLARY 6 NUS.

Dr. St. Clair Thomson related a case of empyema of the maxillary sinus, undoubtedly of two years' and probably of seven years' duration, with persistent cough

and regularly recurring headache, which was completely cured in eight weeks by simple drainage through a tooth socket. He recorded the case, because there was a tendency on the part of some rhinologists lately to disparage the method of treatment through the alveolar border, which was first employed by Cowper as long ago as 1698. Indeed, some practitioners held that this method was quite futile in cases of long standing. He quoted a case in which he had positively diagnosed the empyema two years before the print was presented on the long standing. two years before the patient was operated on, and in which the history pointed to the presence of pus in the antrum of Highmore for possibly seven years. During this period the patient had suffered from chronic cough, which had resisted every treatment. She had also for more than four years had what she described as a frightful headache, lasting three days, and regularly recurring with the cessation of menstruation. The maxillary sinus was opened with a drill through the alveolar border; a spiral (Ellis) drainage tube was inserted; and the cavity was washed out once daily with a simple alkaline lotion. At the end of a month the liquid came through quite clear, and doubtless treatment might then have been discontinued. For the sake of security the washing out was continued at decreasing intervals for another month, when the drainage tube was removed and the opening allowed to close. The patient's cough entirely ceased. the headaches never recurred; and the cure was confirmed by observation nine months afterwards. This case suggests that in all cases of empyema of the maxillary antrum—especially where there is already a hollow tooth socket—this simple method of treatment should be tried before having recourse to more severe operative measures. The opening is easily made; the patient is able to carry out the treatment at home; and it does not prevent a more extensive operation later if the suppuration proves intractable. The case also shows that a long history of empyema does not necessarily show that the case will resist cure by this easy method. Mr. T. MARK HOVELL and Mr. FREDERIC EVE read a

paper on

CASES ILLUSTRATING THE PATHOLOGY AND TREATMENT OF CHRONIC IMPYEMA OF THE MAXILLARY SINUS.

The paper demonstrated that chronic antral empyema was frequently associated with the formation of papillary outgrowths from the lining of the cavity so abundant in some instances as to fill it. These could only be effectually dealt with by free opening of the cavity and removal of the growth; and even then they sometimes recurred. Antral suppuration was sometimes the earliest symptom of malignant disease commencing in that cavity. In six consecutive cases related, numerous papillary growths existed in three, a large polypus in one case, granulation in one case, and in only one instance was the lining membrane of the cavity natural. In the three cases presenting well-marked papillary growths suppuration had existed for periods varying from five months to three years, while in a patient with polypoid growth the discharge from the nostril had existed for two or three years. The pus contained streptococci in three cases in which a bacteriological examination was made. Treatment.—This consisted in freely opening the antrum through the canine fossa so that the cavity could be inspected, and the growths removed; and in two instances a counter opening was made through the inner wall of the antrum at the level of the floor of the interior meatus. The cavity was first packed with iodoform gauze, and afterwards treated with antiseptic irrigation. In one case the growths recurred, and the antral wall was again scraped. The three patients whose antra contained papillary growths had previously been treated by tapping through the alveolus and the insertion of a tube without improvement. All the patients were cured except one, who was greatly improved. It was pointed out that the antral growths would tend to increase the mischief by causing retention of pus owing to the blocking of the orifice into the nostril, or such a small opening as could be made through the alveolus. The only treatment likely to be effectual was therefore free exposure of the cavity and removal of the growths. Bare pieces of fangs projecting through the floor should be sought for. The eventh case related was that of a gentleman, æt. 57, in

whom antral suppuration was the earliest symptom of malignant disease in that cavity. On opening the antrum it was found to be filled with carcinoma, the existence of which had not previously been suspected. The superior maxilla was subsequently removed success-

Sir Felix Semon thought that it was possible to treat the great majority of cases of antral empyema success fully by the method of simple drainage through the alveolus, although there appeared to be a tendency among the younger rhinologists in favour of more complicated methods of rocedure. Most of the cases were due to mental trouble. In a minority of cases of some standing there were papillary outgrowths, and then opening and scraping as performed by Mr. Eve and Mr. Hovell were required, but the milder method should be tried first as a routine treatment.

Mr. Charters Symonds agreed that alveolar drainage should always be the first step. In the long standing cases where this did not effect a cure the antrum should be opened, and an independent opening made in the inner wall below the inferior turbinated bone. It was usual in such cases to find polypi or papillary outgrowths.

Mr. W. J. WALSHAM agreed with what had fallen from Mr. Symonds, and mentioned a case in which the empyema was found to be due to a fang which had been retained when the tooth with two other fangs had been extracted.

Mr. Eve, in reply, said that he and Mr. Hovell per-braned simple drainage through the alveolus first The formed simple drainage through the alveolus first cases which they had brought forward represented the minority in which this procedure did not cure the condition.

Dr. St. Clair Thomson, in reply, said that the interesting paper by Mr. Hovell and Mr. Eve tended to confirm his thesis that the simpler method should be tried first. He understood that it was Mr. Hovell's practice to try alveolar drainage in all cases, and that it was only in the resistant cases that he sought the co-operation of Mr. Eve for the canine operation. It would be interesting to know the proportion of cases in which Mr. Hovell had found this necessary. As to how long it was wise to persevere with this simple method, he had himself known of cases which had healed up after having to continue it for eighteen months. On the other hand, there were many patients in whom the secretion of pus continued, but who were so content with the daily washing out of the antrum that they declined further measures.

OBSTETRICAL SOCIETY OF LONDON. MEETING HELD WEDNESDAY, MAY 3RD, 1899.

MB. ALBAN DORAN, F.R.C.S., President, in the Chair.

RUPTURED TUBE FROM A FATAL CASE OF TUBAL GESTATION.

Dr. Addinger showed the uterus and appendages removed post-mortem from a young woman, who died within ten minutes of her admission to hospital. On the previous day, while carrying a tray upstairs, she suddenly felt faint, and was obliged to go to bed. doctor who saw her next day ascertained that she had missed a period, and diagnosed ruptured tube-a diagnosis which was confirmed by Mr. Bland Sutton. On her arrival at the hospital she at once became unconscious and blanched, and in spite of the injection into the subcutaneous tissue of over two pints of saline solu-tion, she shortly afterwards expired. The abdomen was immediately opened, and was found full of blood. The Fallopian tube on one side was infantile in respect of development, and the other had a rupture, from which blood was still exuding. No focus had yet been discovered. The left ovary was large and felt cystic.

Dr. Horrocks questioned the value of the subcutaneous injection of saline solution under the circumstances, seeing that it must necessarily be somewhat delayed in absorption, as the circulation must have been very slow. He would have preferred injecting directly into a vein. He referred to the case of a woman who after one operation for ectopic pregnancy, subsequently developed a second extra-uterine gestation in the other tube.

510 THE MEDICAL PRESS.

Dr. Morris asked whether there were any means of distinguishing between tubal abortion and ruptured tube. That, he observed, was important, because in the case of abortion one need be in no hurry to operate, whereas in the other event early intervention was indicated.

Dr. Eden said he had seen the patient on her arrival, but her condition was already too grave for anything to be done; in fact, she died almost at once. With regard to the injection, he pointed out that before they had completed the injection of the second pint of fluid the first lot had been absorbed, though the whole proceeding did not take more than five minutes. Under such urgent circumstances, he thought it was better to inject subcutaneously than to waste time looking for the median basilic vein.

FIBROID OF THE BROAD LIGAMENT WEIGHING FORTY-FOUR AND A HALF POUNDS (TWENTY KILOGRAMMES) REMOVED BY ENUCLEATION; RECOVERY. WITH TABLE AND ANALYSES OF THIRTY-NINE CASES.

Mr. Alban Doran said:—In this case, where the tumour seems to be the heaviest of its kind on record, the patient was 28, and her last confinement was six years before operation. Shortly afterwards a tumour developed in the left iliac fossa; three years later it became impacted in the pelvis. Dr. Ward Cousins succeeded in pushing it into the abdominal cavity; this gave great relief, but the tumour grew rapidly and albuminuria and anasarca set in. The catamenia remained normal throughout. The tumour grew in such a manner that the lower ribs were not stretched out, but pushed back behind it. In order to spare as much blood as possible, the ovarian and round ligament vessels were ligatured proximally and distally, the capsule divided between the ligatures, which were then tightened, and lastly the incisions in the capsule united, so that after its complete division horizontally, and the securing of the cervix uteri, the tumour was enucleated without loss of blood. The cut edge of the capsule was drawn together with a purse-string suture, its cavity being packed with iodo-form gauze. The serre-nœud was left on the cervix as it answered well its purpose, and lay separated by the capsule and its packing from the peritoneal cavity. Though very weak for a few days, the patient did well. The packing was removed in forty-eight hours; the deep The packing was removed in total cases and cases are cavity soon shrunk up. The author, after reviewing tables prepared by Sänger, Bayard Holmes, and Lang, brought forward a table of thirty-nine cases of "fibroid" (fibroma and myoma) of the broad ligament, with an analysis. In no less than six the patient was under thirty years of age, and in just as many over fifty. Menstruation seemed unaffected, nor was flooding ever noted. In two cases, including the author's, there were renal symptoms, from pressure on one ureter. The growth was often rapid, but in Binaud's case, closely watched for two years, the tumour only attained the weight of 9 oz. The large tumours caused pain and discomfort, interfered with nutrition, but rarely proved painful. In twenty-seven cases, including all under 20 lbs. in weight, the tumour was sessile, embedded in the folds of the broad ligament. In eleven, possibly twelve, the tumour was pedun-culated; in one the pedicle was twisted. In twenty-five cases the weight was given. The tumour weighed over 40 lbs. in one, the case here related; between 30 and 40 lbs. in two; between 20 and 30 lbs. in two; between 10 and 20 lbs. in ten; between 1 lb. and 10 lbs. in eight; and 1 lb. in two. Of the eight pedunculated cases, six or possibly seven recovered from an operation resembling ovariotomy. Six out of twelve simple "enucleations" of sessile tumours died, but all six date before 1890. Vautrin, of Nancy, twice did panhysterectomy after enucleation, saving both patients. Pollosson, of Lyons, successfully enucleated the tumour, deep in the pelvis, from under the peritoneum ("paraperitoneal" method). In three cases the serre-nœud or elastic ligature was applied to the cervix. All re-covered. When the tumour is small, and limited to the side from which it originated, it may sometimes be

safely removed with its ovary and tube, the hypertrophied connecting tissue uniting it to the uterus serving as a pedicle. When the tumour is large, the removal of both appendages and amputation of the removal of both appendages and amputation of the uterus is usually unavoidable. Retro-peritoneal hysterectomy is probably the best procedure, if practicable. The chief duty of the surgeon in enucleation of broad ligament tumours is to avoid loss of blood. The patients are nearly always sickly and anæmic, although flooding does not occur in this class of tumour, and they bear hemorrhage badly. The author urges the method which he adopted as the best way of avoiding loss of blood. Pressure forceps on the distal side are untrustworthy.

RETRO-PERITONEAL FIBROID UNDERGOING SUPPURATION.

Dr. C. H. ROBERTS read notes of a case of large retroperitoneal fibroid, apparently not of uterine origin, also occurring in the broad ligament. Most of the tumour had been converted into an abscess cavity. It, with its contents, weighed 38 lbs. It had only slight adhesions to the uterus. It was removed from a woman. æt. 50, who had never been pregnant. It had first been noticed thirteen years before, and eight years ago was subjected to the electrolytic treatment. During the last month she had lost flesh rapidly. but the only definite pressure symptom was ædema of the feet. The abdomen measured 48 inches. Mr. Meredith removed the tumour, the lower part was solid, but the upper part was tapped, and 13 pints of thin greyish pus escaped. It was completely enucleated, and an elastic ligature applied to the cervix, which was subsequently cut through and removed along with the uterus.

Dr. Horrocks raised the question as to the microscopical signs on which one relied to distingwish between fibroid and sarcoma. When he had asked this question on a previous occasion, he had been told that if the growth recurred it was a sarcoma, and if not, a fibroid; but he urged that one would like something more definite for clinical purposes. He thought that clinically

the President's case looked malignant.

Dr. Maclean recalled that eighteen months ago he had shown a specimen of fibromyoma of the broad ligament, weighing 14 lbs., removed from a woman, et. 39. In the upper part of the tumour was the uterus, three times its natural size, and the ovaries and tubes were pressed to the right side. There was a connection with the uterus on the right side about the thickness of the

Mr. Butler-Smythe pointed out that in view of these cases the uterus was pushed up and the vagina elongated, and he referred to a case which he had seen with their President, in which the top of the uterus was on a level with the umbilicus. Under the circumstances the usual incision would be useless. He thought the President's case was one in which the intra-peritoneal treatment would have been best. He himself had had a similar gigantic tumour to remove, but unfortunately the patient died during the operation.

Mr. Alban Doran, in reply, said he had since had to operate in two other cases of fibroid of the broad ligament, one of them ending fatally, but it was one that had already been tampered with, the patient having four years previously been operated upon in the Colonies by a surgeon, who, finding a cystic tumour, thought it was malignant, and had drained. The wound had never healed, and the condition was septic. On operating he found a cystic sessile fibroid, and he performed retro-peritoneal hysterectomy, but she died 53 hours later from shock and sepsis. The second case was the one he had seen with Mr. Butler-Smythe, and there he operated by the intra-peritoneal method. The patient forty-four years of age, had first noticed the tumour four years pre-yiously. It proved to be a sessile cystic fibro-myona burrowing deeply behind Douglas's pouch. He performed retro-peritoneal hysterectomy, and as he did not care to drain he drew up the capsule firmly from behind the cervix, and sewed it over the flap of peritoneum in front of the uterus. The patient was actually convalescing, but in the second week she had had a sharp attack of parametritis. That he pointed out was always a danger in retro-peritoneal operations, but even so he thought it was preferable to drainage. He could not think the tumour in his original case was malignant, for such a large tumour if malignant would certainly have provoked severe constitutional disturbance, and would have got much softer.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD FRIDAY, APRIL 7th, 1899.

The President, Mr. R. L. Swan, in the Chair.

HEY'S INTERNAL DERANGEMENT OF THE KNEE-JOINT.

Dr. Knott read a communication on this subject, in which he made emphatic objections to the generallyreceived view that this lesion was a displacement of one of the semi-lunar fibro-cartilages of the articulation. He described the signs and symptoms of the condition as it had frequently occurred in his own person, and compared them with the original description of Hey, and the subsequent accounts of other recognised authorities on the same subject. Dr. Knott's own view was that a subluxation of the corresponding condyle of the femur took place, the joint then becoming "locked," with the arti-cular surface of the condyle "over-riding" the prominent margin of the inter-articular fibro-cartilage.

Mr. T. Myles said that the most striking feature of the descriptions in the text-books of this injury was the apparent total ignorance of the ordinary elementary anatomy of the knee-joint. For instance, in a recent work of Allingham's (?) he has evidently never dissected the attachment of the internal semilunar cartilage. He himself had seen a considerable number of cases. In two cases he opened the joint expecting to find a loose cartilage, but found a pedunculated cartilage in the kneejoint. One case had a history pointing to displacement of the internal semilunar cartilage, but he found a small pedunculated cartilaginous body, growing from the front of the joint, projecting between the condyle and tibia. On two other occasions he found the anterior attachments of the internal semilunar cartilage completely torn away. Annandale (?) originated the operative treatment of this condition, but personally he had always failed to attach the semilunar cartilage to the In every case in which he removed a piece of the cartilage the patient always complained of permanent weakness in the joint. Skiagrams of the affection he considered to be most misleading and absolutely futile, and the length of the ligamentum patellæ would be compensated for by the increased contraction of the quadriceps extensor.

Mr. R. C. B. MAUNSELL had removed a semilunar cartilage a year ago from a girl's knee. She had complained for several years of recurrent attacks of the dislocation. Recovery was rapid, and the patient was now perfectly

strong.

Mr. Croly mentioned the case of a gentleman who came to him with one knee slightly flexed and hopping on the good leg; his knee-joint was "locked." He failed to find relaxation of the ligamentum patellæ, nor could he feel anything nummular on the inside of the knee. Extension, followed by sudden flexion, gave instant relief, and patient insisted on walking home. The interesting thing was the slight violence causing the affection, but that applied to all dislocations. The joint was locked in all the cases he had seen. The reason why the external cartilage was not displaced was that the popliteous tendon tied it so tightly in its groove. He thought there was a difference in symptoms of loose cartilage and this affection. The former caused a sickening sensation within the knee itself, whereas the latter caused intense pain over the line of the internal semilunar cartilage. He thought that Mr. Maunsell was very fortunate in the case where he had removed the cartilage, but he did not approve of the proceeding.

ADVANCEMENT OF THE RECTI MUSCLES OF THE EYEBALL.

Mr. Story described the method of advancing the recti muscles in the treatment of strabismus, which he had devised more than three years ago, and had considered to be his own peculiar property till a publication in the "Annales d'Oculistique" had informed him that the essential point in his operation had been anticipated, so far as publication was concerned, by Valude. The essential point is splitting the tendon longitudinally, and suturing each half of it separately to the conjunctiva or sclerotic. Each half is engaged in a loop of suture lying at right angles to the direction of the fibres of the tendon, and the knots are tied over glass beads to prevent the sutures cutting too rapidly through the conjunctiva.

Mr. Benson was impressed by the satisfactory results, the operation not being followed by the disfigurement which often resulted from lumpiness of the edge of the tendon near the margin of the cornea in former operations. He himself had employed a modification of Schweigger's operation, and frequently shortened the tendon rather than advance it to the edge of the cornea, and had been well satisfied with the results. One of the great difficulties was not so much to get a result as to get the result, and it was extremely difficult to measure the amount of result that will be obtained. In his modification of Schweigger's operation it was necessary, in order to avoid strain on the sutures, to put in an anchor suture. The pulley operation was a most abominably complicated thing to do. He thought it probable that for the majority of cases the operation described by Mr. Story would answer the purpose better than any other single opera-

Mr. Maxwell pointed out that when a tendon is advanced it is not the cut end alone which unites to the eyeball, but the conjunctiva having been raised up from the globe, a raw surface is left below and above, and the tendon becomes adherent to that raw surface at the level of its division to the eye. The great objection, he thought, in almost all operations, is that the tendon is divided, and if any slipping should occur, the patient's condition is worse than formerly. Another objection is that the suture is inserted into the tendon at one side, which is firm enough provided the thread is carried across the tendon, but the other end is inserted into the conjunctiva, which is soft and delicate and easily torn. He described a method of his own to obviate slipping, in which tendon was stitched to tendon and the muscle was not divided at all, and even if slipping should occur, the original condition would remain.

Mr. Story, in reply, approved of Mr. Maxwell's operation. He did not think that there was the same chance of one of the sutures giving way in his operation as in many others, because the only pull in his operation was directly along the tendon to the conjunctiva.

HARVEIAN SOCIETY OF LONDON. MEETING HELD THURSDAY, MAY 4TH, 1899.

PEYTON BEALE, F.R.C.S., Vice-President, in the Chair.

ARTHROTOMY FOR THE RELIEF OF PAIN.

MR. C. B. LOCKWOOD related a series of cases of arthrotomy for the relief of pain, an abstract whereof we publish on page 505.

Mr. Howard Marsh insisted upon the importance of the subjects raised in the paper. In regard to pain as a symptom of many joint affections he pointed out the important part played by tension and agreed that in many instances this was best relieved by free incision into the joint. Transverse division of the patella was perhaps the most satisfactory method of freely exposing the interior of the knee. Mr. Marsh had operated in about forty cases for the removal of the internal semiabout forty cases for the removal of the internal semi-lunar fibro-cartilage; in all the result had been satisfac-tory, and in none had any impairment in the function of the joint been recognisable. In a few instances the affection had been met with in women and twice in children under ten years of age.

Mr. HEBBERT ALLINGHAM had operated in fifty cases for one or another of the various conditions mentioned in Mr. Lockwood's paper. The series included eighteen cases in which the internal semilunar cartilage was excised and thirteen in which the dislocated cartilage was sutured in position, and eleven cases in which loose

cartilages and three in which osteophytes were removed. In one case of chronic rheumatism the joint was drained and in three cases although nothing definite was found to explain the symptoms the latter were relieved by arthrotomy. In Mr. Allingham's opinion the most satisfactory view of the interior of the knee-joint was obtained by a longitudinal division of the patella through an incision beginning at the upper part of the joint and continued downwards into the ligamentum patellæ.

Mr. W. J. Walsham had, during the last 18 months, also operated upon about twenty cases of the kind under discussion without any mishap. He insisted upon the importance of careful preparation of the patient for such operation and thought it very advisable to keep the knee fixed on a splint for a week, if possible, beforehand. He strongly advocated transverse division of the patella as the best means of freely exposing the knee-joint. Mr. Walsham agreed that the symptoms of a dislocated semilunar cartilage were often not such as were described in the text-books and might consist of little more than a crack or snap during the movements of the In the treatment of such cases after operation he advised that movement should be commenced at the end of a fortnight and that the patient should be allowed to walk at the end of three weeks.

Mr. Jackson Clarke referred to the case of an athletic man who had had pain in a knee-joint for four years, originating in a sprain sustained in playing golf. symptoms were so severe that at first it seemed likely that the joint would require to be opened Mr. Clarke, however, first tried the effect of a support that prevented lateral and rotation movement at the knee. This measure proved successful, and enabled the patient to play football, polo, and other vigorous games. At the end of a year the apparatus was left off and the patient

had no further trouble.

Mr. RAYMOND JOHNSON referred to a case in which suppuration in the knee-joint followed an operation for the removal of a semilunar cartilage. He at once drained the joint by free lateral incisions, and recovery followed with a very fair amount of movement. He believed the infection of the joint took place from the skin, and was in part accounted for by the fact that at the time of the operation there was still a good deal of fluid in the joint. It was certainly much safer in these cases to delay operation until the attack of synovitis had subsided. A question was asked as to the probable nature of some cases of diffuse villous synovitis in which there were no definite evidences of osteo-arthritis. The speaker also referred to the comparative rarity of the origin of loose cartilages in joints resulting from detachment by injury of a portion of the articular surface.

The CHAIRMAN congratulated Mr. Lockwood upon the success with which he had followed up such a considerable series of cases. The long villous processes found in the synovial membrane in some cases of rheumatoid arthritis were microscopically identical with the villous processes normally found in the rabbit's knee, and which had masses of mucoid material projecting from them.

Mr. Lockwood replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD ON APRIL 18TH.

The President, Dr. BERRY, in the Chair.

DR. ENRICH gave a microscopical demonstration.

Mr. Hall showed (1) a small dermoid cyst of the ovary, in which there were three cavities, the first contained hair, the second teeth and bone, and the third a mucoid fluid. (2) A calculus removed six months after lithotrity.

Dr. Kerr showed a case of optic neuritis following

Dr. RABAGLIATI showed the pelvic organs with some intestine removed post-mortem from a patient who had suffered from fæcal fistula, following pelvic abscess.

Mr. WILMOT showed a patient suffering from

acromegaly.

Dr. METCALFE read a paper on the

OPERATIVE TREATMENT OF UTERINE CANCER. Afteralluding to a case of cervical cancer which he had

recently had under treatment, Dr. Metcalfe discussed the relative propriety of the operations of supra-vaginal amputation, and of vaginal hysterectomy. While admitting that there was a very large body of modern opinion in favour of complete hysterectomy he cited Schröder, John Williams and others who advocated supra-vaginal amputation, and pointed out that the immediate mortality from hysterectomy was higher than from supra-vaginal amputation, while the recurrence rate was no lower. The advocates of hysterectomy say that the high recurrence rate is due to the fact that hysterectomy has been reserved for more severe cases. while supra-vaginal amputation has been practised on the early cases. Dr. Metcalfe then described the distribution of the pelvic lymphatics, and expressed the opinion that it is impossible by vaginal hysterectomy to remove the whole of the diseased area, together with the lymphatic glands, and consequently that if the disease has spread beyond the limits of the uterus, recurrence is probable after either hysterectomy or amputation of the cervix.

Drs. Rabagliati, Wood, Hall, and Althorpe discussed the paper, and Dr. Metcalfe replied.

Mr. MIALL read a paper on

CONTAGION FROM A HISTORICAL POINT OF VIEW.

He said: Disease was considered transmissible, in very early times, by charms and ceremonies, some of which are still extant. Ideas of cleanness and uncleanness, which are almost universal among primitive people, also involved the idea of contagion which prevailed at the dawn of history in Egypt, Persia, and Greece. In India inoculation for the small-pox was practised by the priests still earlier. Thucydides records the contagious character of the plague at Athens, B.C. 430, and about the same time Hermippus, the comic poet, mentions the itch as transmissible. A little later Isocrates alludes to consumption as contagious, and Aristotle has no doubt of the contagious nature of the plague. But the strictly medical writers in Greece before the Christian era ignore contagion. They account for epidemics by noxious airs, influences of celestial bodies, eclipses, tidal waves, earthquakes, famine, wars, and other causes affecting many at the same time. The Greeks had no word for contagion, but they expressed the fact in numberless ways, quite unequivocally. Aretæus was the first medical author who recognised contagion at all, this was in the second century, A.D. Lucretius first uses the term contagion, which soon acquired a technical meaning. He was followed by Virgil, Ovid, Livy, and most Latin authors, except the medical writers. The latter do not allude to the subject till we come to Cœlius Aurelianus, though the Greeks had long adopted the notion. Bubonic plague can be traced back further than any epidemic disease; it is now possible to identify it in the sixth century, AD., when it pervaded the Roman Empire, eastern and western, for fifty years. According to Gibbon, it depopulated the most flourishing countries, some of which have never recovered. In three months, five to ten thousand persons died daily at Constantinople. At this time, Mayrius looks upon it as decidedly contagious, while Procopius, another contemporary historian denies contagion in strong terms. For a thousand years after this the same disease appeared at intervals in every country in Europe. The recognition of small-pox by Rhazes in the tenth century was an important event in the history of epidemics, for though the disease had probably appeared long before, it was not properly marked off by physicians. From that time messles, chicken-pox, and ultimately scarlet fever, typhus, and enteric fever were gradually analysed and separated from one another. The belief in contagion was gradually placed on a firmer foundation. Rhazes does not lay much stress on it, though he admits that smallpox and measles are contagious. He dwells principally on the great susceptibility of children, and the less susceptibility of older persons. There are thus three lines of thought in ancient history in regard to epidemics. The idea of contagion, that of the patient's susceptibility, and that of a common cause for epidemics. These three theories still contend with one another.

France.

FROM OUR OWN CORRESPONDENT.

Paris, May 13, 1899.

PULMONARY CONGESTION WITHOUT EXPECTORATION. AT the last meeting of the Medical Society, M. Rénon spoke on certain cases in which affections of the lungs in the adult followed their course without expectoration. In the pulmonary congestion of Woillez the absence of expectoration was the exception. Woillez remarked it once and the speaker knew of four other examples. In the pleuro-pulmonary congestion of Potain expectoration was the rule, and he found on record but one case where it was absent.

In spleno-pneumonia that absence was much more frequent, and influenza, by modifying considerably the regular evolution of pulmonary congestions, had contributed to the frequency of the phenomenon, M. Huchard insisted on a new form, which he styled bronchoplegia, in which the patients did not expectorate, and which was due to the action of the influenzal poison on the pneumogastric.

The common features of these congestions were violent dyspnea and a double souffle, with a slight sound of bronchophony. In the majority of cases the absence of the expectoration did not much influence the evolution of pulmonary congestions, consequently the prognosis need not be modified. Exception should be made, however, in respect of bronchoplegia, which was frequently fatal.

THE TRUE CAUSE OF APPENDICITIS.

M. Taisans said that for a long time already different authors remarked a coincidence between appendicitis and certain affections of an influenzal nature, hence the conclusion that influenza might under certain circumstances engender appendicitis. For him this variety, far from being the exception, should be considered as the rule, as appendicitis breaks out in the course of an attack of influenza, or sets in some time after that attack. In any case the relation of cause and effect between the general malady and the affection of the appendix was extremely probable.

This view of the etiology of appendicitis furnished the only explanation of two facts of incontestable reality; viz., that appendicitis had become extraordinarily frequent within the last ten years, that is to say, since the great epidemics of influenza made their appearance. In the second place each annual epidemic of influenza is accompanied by a kind of epidemic of appendicitis. The speaker concluded by saying that in his opinion the true cause of appendicitis was influenza. An Incubator ad hoc.

A medical journal relates the following curious incident. A young girl became passionately fond of a young man who finally refused to marry her. The parents of the disappointed belle brought an action against the obstinate flance for seduction. A medico-legal examination was ordered by the court, which revealed the linen stained with blood and the hymen ruptured. The girl declared that she had a violent struggle with her seducer before he committed the act. No trace of violence, however, could be found on her body. On examining the vagina the medical expert was no little surprised to find an oval smooth foreign body there, which turned out to be a hen's egg! In the extraction it broke, and was received in a semi-liquid state in a basin. The most curious part of the affair would have been if the egg

previously fecundated had sojourned the necessary period in the vagina of the young virgin transformed into an artificial incubator. She would have been delivered of a chicken, and the medico-legal question would have been complicated with a problem of teratology.

PREVALENCE OF TYPHOID FEVER.

The seasonal increase in the prevalence of typhoid fever in Paris is once again exciting public attention in a disagreeable way. Interested pleas are continually being put forward with the view of exonerating the water supply from the responsibility, and it is quite possible, after all, that the extensive disturbances of soil which have been entailed by the preparations for the approaching exhibition may have contributed to swell the death-roll. Although water pollution is always the principal factor in the productions of widespread epidemics, there are many other possible sources of infection open to explain the numerous more or less sporadic cases. Foremost among them is the deplorable condition of Paris from a hygienic point of view. There are special technical reasons for suspecting the water supply, too intricate for explanation here, but a powerful Government department is interested in proving that all is for the best in the best of worlds, the large number of deaths from such an eminently preventible disease as typhoid fever to the contrary notwithstanding.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 13th, 1899.

AT the Surgical Society Hr. Eiselsberg, Königsberg, read a paper on

HEMORRHAGE FROM THE STOMACH AFTER OPERATIONS During the past three years he had observed hæmorrhage from the stomach after operations in six cases in seven years in the Königsberg Klinik. (1) The day after Bassini's operation; (2) after hæmorrhage and ligature of omentum; (3) after omental hernia; (4) after extirpation of carcinoma of the rectum, there was no hæmetemesis, but collapse and death on the fifth day; the autopsy revealed numerous hæmorrhages in the mucosa of the stomach and peritonitis; (5) strangulated hernia, replacement, purulent peritonitis, death in three days; in the stomach were 30 fresh erosions; (6) ileus laparotomy, torsion of omentum, hæmatemesis, death; the autopsy showed peritonitis and fresh ulcers of the stomach, of carcinoma of the rectum, extirpation; the wound did well, but on the ninth day collapse, black stools and death, the autopsy revealed a deep duodenal ulcer. There could be no doubt as to the causal relation between the operation and the hæmorrhage. Vomiting after narcosis could not be the cause, as in two cases there was no vomiting; in six cases, however, there was ligature of the omentum, and in the seventh the omentum was probably contused. In an experiment on an animal, multiple hemorrhages into the stomach followed twisting of the omentum.

Hr. Konig, jun., Berlin, related a case of PERSISTENT VOMITING.

The patient, a woman (shown), had suffered for fifteen years from persistent vomiting, at last all food was In June 1898, posterior gastroenterostomy was performed, but with no benefit, and six weeks later a second attempt was made. This time the two loops of intestine were united by Murphy's button, but again no good resulted, the vomiting still continued. The patient then came to Berlin under v. Bergmann's care, when laparotomy was again performed. The bowel was firmly attached to the stomach and lay behind it. It was closely sutured to the stomach, and a communication made between the two loops. A further gastroenterostomy was made, this time anteriorly with attachment of a broad piece of bowel. The result was good, the vomiting ceased entirely and the nutrition was good. She had gained 6 kgrm. in weight.

Hr. Braun, Gottingen, performed gastroenterostomy in November, 1897, on a man, æt. 25, who suffered from severe gastric troubles. The patient did well. Eleven months afterwards acute peritonitis came on and he died. The cause, as shown by the autopsy, was perforation of the jejunum some centimetres from the stomach, from an u'cer, apparently caused by outflow of gastric juice.

Hr. Kahn related a similar case. A year after successful gastroenterostomy acute abdominal pain came on with death within twenty-four hours. A perforation had taken place, where the jejunum joined the stomach. Anterior ante-colic gastroenterostomy had been performed.

Hr. v. Bech, Carlsruhe, reported a case of gastroenterostomy with Murphy's button. After some months renewed acute symptoms of ileus made a second laparotomy necessary, when the Murphy's button was found firmly seated in its original position. After this the button descended spontaneously, and the symptoms disappeared. As the cause of illness he had found in some cases acute flexion of the intestine from adhesions In one case obstruction of the bowel was found to be caused by a tumbler belonging to a bedroom water-bottle fixed in the rectum. This was with difficulty removed without breaking. This patient then called to mind that once, on getting out of bed, he had sat down suddenly on the water-bottle, with the tumbler placed in an inverted position over it. The neck of the bottle was smashed, and the tumbler, which he thought was also broken, had passed up into the rectum!

Hr. Kader, Breslau, related the case of a woman who had been operated on by a gynæcologist. Ten days later ileus-like symptoms came on. The wound was reopened and the patient remained under treatment for six months, and at the end of that time she was discharged improved. But again symptoms resembling ileus came on, and the patient became very weak. Then a piece of cloth, the size of a pocket handkerchief, was removed from the rectum, which had plainly been left in the abdomen, and had found its way into the bowel. Later on, acute strangulation took place and peritonitis. At the laparotomy a loop of small intestine was found kinked and gangrenous in the pelvis. Death. At one part of the intestine a cicatrix was found, the point of entrance of the cloth. In order to study the passage of foreign bodies out of the peritoneal cavity into the bowel. he performed the following experiment: He drew an indiarubber ring round a piece of bowel and returned it into the abdominal cavity. Later on the ring had become embedded in new growth around it, and still later it had passed into the bowel, the wound in the intestine being closed with a cicatrix.

Hr. Hadlich, Kassel, recited the case of a man on whom laparotomy was performed. At the operation the colon

was found to end in a blind pouch, a space a handbreadth in width separating the two blind ends. The destruction of the intervening portion had probably been caused by adherions, resulting from appendicitis.

Hr. Henzel recited a case of the long continuance of a foreign body in the abdominal cavity. Six years ago a young man had been operated on for echinococcus of the abdominal cavity. The operation was tedious, and as collapse threatened the abdomen was closed in a hurry-The patient recovered. Fourteen months afterwards he felt violent pain in the region of the sigmoid flexure, with drawing up of the left leg and a tumour on the left side of the abdomen. Echinococcus was again diagnosed. The abdomen was opened, a large quantity of exudation was found, and in the midst of this a large torsion forceps, which must have been left in at the first operation $2\frac{1}{2}$ years before. The patient recovered.

Austria.

FROM OUR OWN CORRESPONDENT.]

VIENNA, May 13th, 1899.

HYSTERIA.

At the Medical Club, Schlesinger showed a female patient, et. 16, with peculiar movements of the head which were probably hysterical as she formerly had other marked nervous movements that suddenly disappeared In the present illness the movements of the head were backward, and in order to control them the finger had to be put in the mouth in order to hold the head forwards.

ESTIMATION OF PHOSPHORUS IN THE BLOOD.

Dr. A. Jolles exhibited an apparatus which he has devised for the measurement of phosphorus in hæmatic analysis. Where the phosphorus is present only in small quantities as in the blood the process is usually long and tedious, but with Jolles' phosphor-meter the operation is greatly simplified. In his demonstration he referred to the essential elements of the blood cells and emphasised the fact that it must not be considered a simple albuminous body, but one containing a phosphatic proteid or, as Kossel has aptly termed it, nucleoalbumine. Smith had isolated albumen and cytoglo bin from the red corpuscles, and altogether these are not complete. A group of nucleo-proteids have been formed. Recent investigation of the albuminous part of the leucocytes and "nucleo-histon" show them to contain 3.025 per cent. of phosphorus which form by decomposition a nucleïn or leuco-nucleïn with 4.7 per cent. of phosphorus, the peculiar feature whereof is its combination with an albuminous base. It is acknowledged that the flat corpuscles have homogenous contents and mostly of albumen the nucleus contains the nuclein. The non-albuminous substance of the cell is richer in phosphorus as in lecithin, which by its acid combination plays an important part in the blood. The relative proportion of phosphorus in the normal blood is constant in the leucocyte' but whatever its function may be there can be no doubt as to its importance. In pathological conditions it is often increased or diminished in the presence of microorganisms, poisons, or other foreign bodies. when the task of the leucceytes seems to be to change injurious into innocuous material.

The bacterial foundation of a bacterial property in the leucocyte has been more than once repeated in the

publications of Kossel, Metschnikoff, Roux, Hahn, Schattenfroh, &c., which would lead us to the conclusion that there must be some enhanced property of the cell to assume a defensive attitude towards infection by causing an increased secretion of alexine. With this knowledge, the destruction of red blood corpuscles and the increase or modification of leucocytes or other constituents would probably increase the average amount of phosphorus, which could be early recognised as a pathological change. In the normal condition blood serum contains very little lecithin, or debris, as well as phosphate of soda. He therefore concludes that the phosphatic contents of the cell comprise the total phosphorus, while the serum has relatively very little in the normal condition. An examination, to be of any practical service, must have for its object the determination of the phosphorus present in the cellular element as well as the

The principle of his method is the depth of colour produced by potassium molybdate when heated to 80 degs. C. (176 Fahr.). In order to separate the phosphorus from its various combinations in the blood, it is first evaporated to dryness, and carbonised and subsequently dissolved in soda and nitre (3.1) with the addition of a little nitric acid. It is again evaporated, and afterwards re-dissolved in hot water, when it is ready for the colorimetric apparatus. Hitherto the inaccuracy of the colorimeter when compared with gravimetric estimation have rendered the results very fallacious. To overcome this source of error Jolles has devised his phosphormeter, which is a combination of various tubes containing different quantities of phosphorus, under similar conditions which thus can be easily compared with the substance under examination. In conclusion, he gave a demonstration of 22 healthy cases where the blood cells and blood serum contained fixed quantities according to age sex, and mode of life.

The Operating Theatres.

MIDDLESEX HOSPITAL.

LARGE FIBRO-CYST OF UTERUS WITH AN OVARIAN Tumour.-Dr. William Duncan had under his care a patient, æt. 55, who, after undergoing a fatiguing walk, suffered with acute abdominal pain. She was found to have acute peritonitis, and this, under appropriate treatment, passed away, and then a cystic tumour was detected in the abdomen, reaching up to the level of the No vaginal examination was made, the patient being a single woman. Abdominal section was performed, and when the peritoneal covering was opened a large cyst, having all the appearance of an ovarian cyst, presented itself. There were numerous recent adhesions over the surface; these having been broken down a Spencer Wells's trochar was inserted into the cyst and about two quarts of clear serous fluid drawn off, and the emptied cyst was drawn out of the abdomen: it was now found to have a solid portion at the base and this again was found to be springing from the fundus uteri by a fleshy pedicle about an inch in diameter. This last was transfixed with silk and tied. Peritoneal flaps were cut and reflected down, then the tumour was cut across about half an inch above the level of transfixion. The stump was covered over by continuous sutures drawing together the flaps of peritoneum. On

passing the hand down into the pelvic cavity this was found to be filled by an unilocular ovarian cyst about the size of a cocoanut. This was removed in the usual manner and the abdominal walls sutured in three layers. Dr. Duncan remarked that this case presented some interesting features :- 1. That the patient had not only a large pelvic cyst of the uterus, but also an ovarian cyst filling up the pelvis of the existence of which she was absolutely ignorant, nor had they caused her any symptoms whatever until the onset of the peritonitis after her long walk. 2. The tumour felt through the abdominal wall, and also seen after the opening of the abdomen, had all the signs of an ordinary ovarian cyst, and it was only after the drawing out of the collapsed cyst from the abdominal cavity that it was found to be a fibro-cyst springing from the fundus of an uterus which was in itself perfectly normal in size and appearance. 3. The pelvic cyst, although free from adhesions, could not be drawn up until strong pressure was made by the fingers of an assistant per vaginam. The patient made an uninterrupted recovery.

WESTMINSTER HOSPITAL.

DOUBLE CASTRATION FOR TUBERCULOUS DISEASE OF BOTH TESTICIES.—Mr. WILLIAM TURNER operated on a man, æt. 42, who had been admitted with swelling of both testicles; that of the right one commenced two months ago and gradually increased in size; it was tender at first, but lately has become insensitive; the left testicle commenced to swell a month ago and was still tender and There was no tuberculosis history in the nainful. patient's family, and his children were all alive and quite healthy. He lived in the country and there was no cause so far as he knew for this condition. The epididymis of both testicles was very much enlarged, and also hard and irregular. At the posterior and outer side of the right epididymis there was a fluctuating swelling which was firmly attached to the skin and not translucent. The vas deferens on either side was markedly thickened though the structures of the cord were not affected. There was an inguino-scrotal hernia on the right side, and on examination per rectum a craggy mass about the size of the end joint of the little finger was found in the position of the right vesicula seminalis, the prostate too was slightly enlarged and tender. The left vesicula was apparently normal. He had been complaining lately of some frequency of micturition, and the urine contained a slight amount of albumen, though there was no definite indication of pus. There were no signs of phthisis or of any other tuberculous lesion elsewhere. On the left side an incision was made over the external ring, the structures of the cord divided the testicle shelled out of the scrotum through the opening, the vas and the blood-vessels ligatured separately, and divided as high as possible, and the testicle removed. On the left side the incision was carried right into the scrotum, and the adherent skin removed with the testicle en masse. Above, in the inguinal region, the incision was carried well external to the internal abdominal ring, the external oblique was slit up, and the sac of the hernia isolated; the sac had a large sub-peritoneal lipoma attached to it lying in the canal; the lipoma was removed and the sac freed; the structures of the cord were then separated from their coverings, and the vas isolated. The vessels, &c., were ligatured and divided, as on the other side, and the vas separated down about two

inches, through the internal ring to the brim of the pelvis' ligatured, and divided, the end being touched with pure carbolic, as there was some purulent fluid in its lumen-The hernial sac was transfixed and ligatured, after Mitchell Banks' plan, and the canal closed by McEwen's method, the external oblique being sewn up with a continuous suture. The whole wound was brought together with a continuous silk suture, a drainage tube being inserted in the lowest part of the scrotum. Mr. Turner said that he had advocated this operation in preference to simply opening and scraping the abscess, particularly owing to the fact of the vesicula seminalis on the right side being markedly affected, and the probability of some further trouble in the urinary tract in consequence of the albuminuria and of the enlargement of the prostate. The ultimate prognosis of cases of this description, he remarked, appears to be bad, owing to the early affection of the prostate, bladder, and kidneys, but he thought it seemed only reasonable to hope that a free removal of so great an amount of the disease might give the patient a better chance of recovering from the rest of the trouble. It was quite evident, he pointed out, that the testicles were perfectly useless to him as sexual organs, this being borne out by the patient's history. As regarded the immediate prognosis, he thought there did not appear to be any reason why the patient should not go on satisfactorily; but it might be interesting to see whether the affection in the lumen of the vas on the right side would affect that part of the wound with tuberculous disease, and ultimately lead to the formation of a tuberculous sinus. He did not consider it justifiable to continue the separation of the deep parts for the removal of the remaining portion of the vas in the pelvis, as that would have involved the complete removal of the right vesicula seminalis, and this, he thought, would have been very heroic treatment. He hoped, with the removal of the greater part of the disease, the remaining portion of the vas would gradually shrink with the improvement of the patient's general health. He did not anticipate any nervous symptoms, such as dementia or mania, to follow the removal of both testicles, as they were both greatly affected with tuberculous disease, the double castration of normal testicles, however, he pointed out, having often led to such effects.

Vital Statistics.

The deaths registered last week in the thirty-six great towns of the United Kingdom corresponded to an annual rate of 16.5 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 18, Birmingham 16, Blackburn 13, Bolton 19, Bradford 18, Brighton 17, Bristol 15, Burnley 16, Cardiff 10, Croydon 15, Derby 9, Dublin 24, Edinburgh 18, Glasgow 20, Gateshead 13, Halifax 18, Huddersfield 18, Hull 17, Leeds 18, Leicester 14, Liverpool 20, London 16, Manchester 20, Newcastle-on-Tyne 17, Norwich 14, Nottingham 15, Oldham 17, Plymouth 22, Portsmouth 14, Preston 19, Safford 19, Sheffield 14, Sunderland 17, Exansea 14, West Ham 10, Wolverhampton 17. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 2.2 in Manchester, and 2.6 in Bolton; from whooping cough, 1.8 Birkenhead and in Preston, and 2.8 in Burnley; and from diarrhæa, 1.5 in Derby. In none of the large towns did the death-rate from scarlet fever, or from fever reach 1.0 per 1,000.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 17, 1899.

SPORT v. VIVISECTION.

THE National Anti-Vivisection Society of Great Britain has had another gala day. Our readers will remember at the former great foregathering held a few weeks since, the promoters killed the fatted lamb over an "eminent" surgeon, who alone of the elect of medicine had joined their standard. The fallacies of the arguments advanced by their pillar of support were pointed out at the time not only in our own columns but also in those of several of the leading lay newspapers. This second meeting at St. James's Hall, following hard on the heels of the first, was not sanctioned by a single member of the medical profession who has established any claim to scientific consideration. A number of titled folk, with the aid of a few church dignitaries, met together and showed their profound ignorance of the methods and meanings of vivisection, while they calmly assumed the right to guide mankind in the regulation of a branch of experimental science of which they clearly had not touched the fringe. One speaker, a type of the sentimentalist, sincere, eloquent, titled, narrow, maintained that the Society was engaged in one of the noblest causes that had come before the nation since the abolition of slavery. To prolong human life by the torture of animals was morally wrong, and if the vivisectors could make us live a hundred years it would be a miserable exchange for the extinction of pity in the human heart. This curious piece of antivivisectionist metaphysics is 1 iddled with the fallacy of assumption. Let us see how far it will hold water. If it be wrong to prolong human life by the torture of lower animals (admitting, for the sake of argument, that questionbegging phrase), surely it is no less wrong to kill them for the purpose of sustaining life.

Digitized by Google

should all become vegetarians or die the But it is a moot point if there be not a remote common origin of vegetable and animal life. At any rate, the vegetarian destroys alien life every time he eats an onion or munches a radish. The vegetarian then supports his own life by means that are more cruel, inasmuch as they involve destruction of alien life, than the methods of the vivisectionist who merely "tortures' - again accepting an absurd term-lower animals to subserve the welfare of humanity. But what is the position of our gentle metaphysician towards the sportsman who tortures the lower animals for mere purposes of amusement and recreation? For an answer to that pertinent question we may turn to the utterances of his chairman, the Duke of Portland, who has at length answered the repeated challenge thrown down to the anti-vivisectionists upon the matter of sport. The downright views of the noble lord are those of an avowed sportsman. Let us examine them. The object of the sportsman, said he, was to kill his quarry outright with as little pain as possible. Then why does his grace not shoot tame deer instead of pursuing them as Master of the Queen's Buckhounds over half a county? Surely instantaneous death inflicted by a cartridge would be better for the deer than being flayed and disembowelled by barbed wire fences and being torn to pieces Moreover, "the object by savage dogs. the sportsman" — as defined by the Duke namely, to kill his quarry outright with as little pain as possible, would be certainly and absolutely attained by the keeper's gun. As with deer, so with foxes-Then the noble chairman went on to advance the extraordinary argument that sport, and the laws that protected it, were the greatest friends to the animals pursued, because if it were not for sport they would very soon be extinct, and would no longer exist except as specimens in the Zoological Gardens. We presume his Grace speaks of protected sport, because the extinction of wild animals, as, for stance, the giraffe and elephant, is being effected at this present moment in Africa still in the sacred name of sport. What animals the speaker had in view it is hard to imagine. Does he assert that the fox and the deer would become extinct in England if they were not hunted and shot? If so, we very much question whether they would thrive and multiply multitudiuonsly were they no longer the object of the tender solicitude of sportsmen. Pheasants and partridges are not indigenous to this country. We venture to assert that the United Kingdom would not be a penny the worse were every animal now the object of sport in the country extinct within a couple of years. Nay, more, it may be pretty safely asserted that agriculture and the productive power of the nation would be benefited thereby, although the sportsman, titled and otherwise, would have to seek his diversion in other directions. Henceforth it must afford a comforting if somewhat grim satisfaction to every sportsman that the animal he is pursuing with intent to kill is deriving solid benefit from his kindness. Bad for the individual the chase undoubtedly

must be, but think of his kindred and his posterity saved from the obscurity of the Zoological Gardens. What creature would think of the terrors of a flight for life from the fangs of a bloodthirsty pack. when the survival of his species was at stake? Then came the Duke's trump card, so to speak, in this flourish of sportsman rhetoric. Sport tended, so he explained to his enthusiastic following, to the better understanding of the case, the requirements, and the natural habits of animals, which knowledge was absolutely necessary to keep them in health and therefore in the enjoyment of life. To round off his argument he need only have added that sport tends to the better knowledge of how best to kill the unfortunate lower animals which it is his tender object to keep in health and enjoyment of life. The fox and the deer that head the run across country may henceforth be happy that they are kept by the sportsmen out of the hands of the accursed vivisectionists in order that their health and happiness may be maintained—that is to say—up to a certain pitch, and apart from such accidents as barbed wires or railway engines, or the attentions of sharp-fanged hounds.

To the merely scientific onlooker it would seem that the experimental investigation of disease conducted upon the lower animals would lead to a sounder knowlege of how to prevent and how to cure their maladies. Pasteur, who made and confirmed his discoveries by means of vivisection, was enabled to stamp out anthrax in the herds of Europe. The saving of suffering involved in that simple statement is incalculable. A fact of that kind, however, hardly falls within the limited knowledge of the anti-vivisector, which rarely extends beyond the "torture trough" and the "cruel and degrading practices" of vivisection—that is to say, words that declare his mind to be made up before he approaches the discussion of the subject. The Duke of Portland believes that horses are better looked after in Great Britain because we are a nation of sportsmen. That may be so; but we venture to say that any day his Grace will find more cruelty to horses in one short street in a busy City than he would find in twenty years of vivisection. His Grace is Master of the Queen's Buckhounds. We have often commented on the gross cruelty to tame deer hunted under his auspices. He has now broken silence, and under cover of a veiled attack upon the medical profession has indirectly proclaimed to the world his defence of that species of sport which seeks to promote the comfort of the "carted" tame deer. We trust Her Majesty will carefully consider the views advanced by the Duke of Portland at St. James's Hall.

THE NEW REGISTERS.

THE General Medical Council has issued the "Medical and Dental Register" for 1899 within the past week, nearly a month later than last year's date, and nearly two months later than

the date of some previous issues. Probably the increased size of the Medical Register may account for some of this delay, but it is a coincidence that the lapse of punctuality has occurred just after the retirement of Mr. Miller from the Registrarship and the accession of Sir William Turner to the Presidency. The total strength of the British medical profession, as represented by the Register, is 35,057, and of the dental speciality 4,966, the medical practitioners having increased by 415 since last year, and the dentists only by 29, this discrepancy being accounted for by the gradual dying off of the mob of chemists' boys, tobacconists, and such-like who obtained admission to the Dental Register without qualification in 1878. It is more than twenty years since Mr. Tomes and Sir John Lubbock inflicted on the dental speciality this blow, and there still remain 3,217 such practitioners to be disposed of before dentistry can assume its proper status as a speciality We have said that the total strength of the profession holding British qualifications in all parts of the world is represented by the Register to be 35,057, but, as we have repeatedly pointed out, the official list affords only a widely approximate estimate of the actual number of qualified men. As anyone who has to do with the compilation of medical directories knows, a very considerable number who obtain qualifications never register at all. At first it is incumbent on them to save the £5, which the process costs; afterwards, when they have established themselves in practice, they, in Ireland or the colonies, gain very little by registering because they very rarely are called upon to sue for their fees. Furthermore, if they succeed to a property or to a monied wife, the probability is that they drop the profession altogether, and never appear in the official list from first to last. Then there are the men who die, but whose names remain on the Register for years afterwards. The compiler of the Register cannot deal with these cases as a directory compiler would do, for, before he erases a name he must, even if he saw the man die, send to his registered address two registered letters at an interval of three months asking whether he is alive or not. But, again, the individual may not have died, but simply migrated, in which case, after his name has been erased, he may turn up again, and a long process and payment of a renewal fee must be gone through before he can be restored. All these sources of error make the Register quite unreliable in many respects. We make these observations because some of our comtemporaries have been grumbling at the inaccuracy of the Register, and we do not think it fair to the compilers to lay upon them the blame which is chiefly attributable to the law. Much, however, may be done by watchfulness. Before the regime of Mr. Miller as Registrar the Register teemed with mistakes, and he reduced it to comparative accuracy by persistent ferreting out of the dead and migrated men. We have, as yet, no reason to doubt that the new Registrar inherits his energy in this direction.

VENEREAL DISEASE IN THE NAVY.

THE recently issued statistical report of the health of the Navy for the year 1897 contains some interesting figures regarding the prevalence of venereal disease in the Service during that period. The total force of officers and men afloat was 80,540, and out of this number 11.906 cases of venereal disease returned. The cases admitted of following classification:—Primary syphilis, 3,956; secondary syphilis, 2,177; gonorrhea and its sequelæ, 5,773. Again, 218 men were invalided in consequence, and there were ten deaths. In comparison with the previous year, the ratio per 1,000 cases of primary and secondary syphilis shows a slight increase in 1897, and contrasted with the average ratios of the last ten years, there is an increase in the latter disease, but a decrease in the former of 5.39 per 1,000. Furthermore, a slight increase for 1897 is also apparent in the ratios for gonorrhœa and its sequelæ. The report shows that the ratio of cases per 1,000 for primary syphilis was 49.11; for secondary syphilis, 27.03; and for gonorrhea and its sequelæ, 7167. must be conceded that these figures are very high, and far beyond what might be the case were efficien t control exercised in the prevention of contagion. The question of invaliding, moreover, must always be a serious one, but this is nothing in comparison with the loss of time and labour incurred by the men being placed on the sick list while suffering from venereal disease. Approximately about 12,000 men were unable to do their necessary duties for longer or shorter periods during 1897 in consequence of attacks of syphilis or gonorrheea. On the China station the number suffering from the latter disease reached the enormous total of 118 per 1,000. It is not needful to tax the imagination in order to determine what the result of this loss of effective strength would be to the Service in the event of hostilities. And after all this is the point of view from which the subject should be viewed. Social purists, with, of course. the best intentions, cannot, or will not, see that the evil arising from the dissemination of foul diseases must be worse in its effects than the offence against morality by which that dissemination is brought about. Surely our first duty in the interests of humanity is to prevent disease. If the reasoning of the social purists were carried to its logical conclusion it would be an offence against religion for man to interfere with the dissemination of disease in any form. Fortunately, however, there is no danger of such a condition of affairs ever becoming an "article of faith" outside the confines of that limited but misguided sect, the "Peculiar People." Nevertheless, one of the worst features of the whole matter is that the social purists are for the most part utterly ignorant of the oftentimes terrible effects of venereal disorders upon the health of the victims. The former may or may not know that a disease like constitutional syphilis is an hereditary one which is apt to play havoc with the offspring of syphilitic parents. They probably know nothing of the pitiable state into

which a young wife may be reduced by gonorrhoan conveyed to her by her infected husband. These and other matters bearing upon the question at issue cannot be ignored; under present circumstances, however, it would seem to be the case that the race, or at least some portion of it, is exposed to serious degenerating influences in consequence of the sentimental opposition of those who are ignorant of their subject. Wiser councils in time may prevail but meantime much harm is being done by the absence of measures designed to control the dissemination of venereal disorders.

Rotes on Current Topics.

Coley's Fluid in Sarcoma.

Not long since, Mr. Battle brought before the Medical Society of London a very remarkable case of sarcoma which had completely subsided under the influence of injections of Coley's fluid. The case excited a good deal of interest, but it was pointed out at the time that growths reputed to be malignant do sometimes undergo resolution, even in the absence of all treatment. Moreover, although Mr. Battle had done his best to establish the diagnosis in his case, it was objected that it did not rest upon an unassailable basis. The question was referred to a committee for further inquiry, and their report has now been received. They express the opinion that the microscopical preparations do not present unequivocal evidence of the sarcomatous nature of the growths, though Mr. Shattock had held that they did; moreover, it was thought that the possibility of the growths being syphilitic had not been absolutely excluded, and it was agreed that the clinical history of the case was, if anything, rather opposed to the diagnosis of sarcoma. The committee rightly enough insist that no conclusions bearing on the therapeutical value of a remedy should be based upon cases which do not present the necessary element of absolute certainty of diagnosis. For the present, therefore, Coley's fluid must be regarded as still on its trial. As it is a method of treatment by no means devoid of risk to the patient, and in view of the extreme difficulty of establishing the diagnosis beyond the reach of carping critics a positive conclusion is likely to be delayed, but it is better so than that a delusive panacea should be foisted on the public only to bring discredit on medical science when experience has shown that it was only a therapeutical Will o' the Wisp.

The Need of Hospital Reform.

THE Charity Organisation Society are doing their best to bring about the establishment of a certain hospital board for London, but all who have paid the least attention to their efforts must feel irritated by the lamentable lack of organisation which they have hitherto displayed in the promotion of that object. Whoever has been responsible for the proceedings so far cannot be congratulated upon the result. One of the most prominent features in their undertaking is that the Society does not seem to be in touch with

those anxious to help forward the movement. Again, they issued a post-card recently summoning a meeting upon the subject, giving the names of various well-known medical men who were expected to speak, one being so described that it was almost impossible to comprehend to whom the secretary intended to refer. This, of course, was only a small detail, but it is sufficient to show that the organisation of the Charity Organisation Society in this regard is more inefficient otherwise. At the meeting. which was held on the 8th inst., Lord Methuen in the chair, an excellent, practical, and useful speech was made by Sir William Broadbent. After pointing out that if a central hospital board were established, such a board would be capable of abolishing to a great extent the prevalent abuse of medical charities, Sir William expressed the hope that a union of the Prince of Wales's and the Hospital Saturday and Sunday Funds would be shortly made. and that the so-called Central Hospital Council would eventually become combined with the proposed central board. No better arrangement than this could be suggested in the interests of the hospital charities, and we are glad to note that these views are held by Sir William. If now Sir William would only gain the ear of the Prince of Wales, and impress upon His Royal Highness how valuable the arrangement would be, he would be doing a great service to the hospitals, besides placing the whole subject of the administration of these public funds upon a proper business basis. Under present circumstances it seems difficult to understand why three separate funds should exist. It would clearly be better if there were one Common Fund, whose administration were placed in the hands of a representative body elected from among all the charities entitled to benefit therefrom.

Christian Scientists in New York.

THE Christian Scientists have hitherto been allowed a great deal of liberty in New York, but the scandal has now become so great that the authorities have been compelled to take action. Several families have been proceeded against on the charge of culpable negligence in not providing medical attendance for relatives who had died, and it is hoped that by taking active measures of this kind, it will be possible to suppress the evil. It is somewhat curious, however, that such irregular practitioners as the Christian Scientists should have found any favour among a practical people as the Americans. In this country a good deal of attention was drawn to the matter by the death of Harold Frederick, but the evidence given at the inquest upon his case revealed some eccentricity on his part in regard to medical men which was sufficient to account for the mistake that he made in having a Christian Scientist to attend him. But that there should be any such persons as Christian Scientists at all is another curious matter. for of all the pretenders among health curers, they form a class which has fraudulency stamped upon it, besides being utterly wanting in any detail of attrac-

A Vaccination Centenary.

THE hundredth anniversary of the first vaccinations in Vienna, and on the Continent of Europe, was celebrated last week in the Austrian capital. On May 10th, 1799, a native of Geneva, Dr. De Carro, who was practising in Vienna, received from Dr. Edward Jenner some vaccine virus, and with it he vaccinated his two eldest sons. Dr. De Carro had made the acquaintance of our great countryman while studying medicine in Edinburgh. Soon afterwards a law was passed stipulating that vaccination should be carried out in the Austrian Army. Meanwhile Dr. De Carro began to prepare the lymph in Vienna according to Dr. Jenner's instructions, and by him it was sent to all parts of the world-for example, to Greece, Turkey, Bombay, Ceylon, and Sumatra. Thus, next to Jenner, it is probably only just to attribute to this Viennese practitioner the credit of disseminating the valuable prophylactic measure of vaccination throughout the world. for the active part which he took in connection therewith it is quite likely that the benefits of vaccination would have been much less quickly disclosed.

The Unqualified Dispenser.

THE General Medical Council has done its best to throw cold water on the outcry against the employment by medical practitioners of unqualified dispensers, and the Government is apparently delighted to have an excuse for leaving matters as they are There is not much reason to suppose that such accidents are common, but it is impossible to gainsay the assertion that if they are frequent the public would not be likely to hear of them, seeing that it rests with the person who has most to lose from a scandal to get the dead past to bury its dead. Still one would have expected the General Medical Council, which has shown such tenacity (of late) in prohibiting unqualified assistants from performing professional duties, to have displayed the same interest in respect of the assistants equally unqualified from a dispensing point of view because dispensing is an essential part of medical practice for the bulk of practitioners. calls attention to the matter and, very cogently asks how it happens that the General Medical Council, which dealt out such Rhadamanthine justice three years ago to the man who was acting as the practitioner's assistant without qualification has so far changed its mind now that it "believes that the best protection to the public is afforded by the responsibility of the practitioner for the acts and defaults of the servants he employs." Truth suggests, which we would not dare to do, that the volte face of the General Medical Council is attributable to the fact that the unqualified medical assistant did frequently become and was likely to become a serious competitor for practice and fees, while the bottlewashing boy could not be dangerous in that sense. The question is likely to come up at the forthcoming meeting of the Council, but we are not sanguine of any progress being accomplished in this direction. During the last few years the most noteworthy measures decided

upon in Council have been introduced at the instance of the Direct Representatives, and the latter are not likely to throw themselves into a movement which could not fail to render them loathsome in the eyes of the majority of their constituents, without, politically speaking, any compensation. The fact that the outcry was started by the chemists and druggists, obviously in deference to trade interests, will not commend it to the profession. Public opinion is not alive to the importance of the complaint, and in the absence of a popular outcry, the unqualified dispenser is likely to pursue the even tenour of his way unharmed by interference at the hands of the General Medical Council or of the Privy Council.

The Baby Incubator in the Law Courts.

An action was tried last week before Mr. Justice Day in which the proprietor of the Imperial Baby Incubator sued Dr. Devane for damages for having failed to carry out an undertaking entered into, in virtue of which Dr. Devane was to examine!babies brought for incubator treatment at the Crystal Palace, and to attend to the health of both babies and nurses. From some cause, or causes, into which we need not enter, matters did not run smoothly, and ultimately a baby died in the incubator. This led to the exhibition being put an end to, and as the plaintiff attributed the mishap to the negligence of the doctor he claimed damages. We cannot help thinking that the managers of the Crystal Palace were gravely to blame for having authorised such a distressing exhibit, \mathbf{and} we fully endorse remarks which fell from the Judge condemnation thereof. There is undoubtedly a sphere of usefulness for baby incubators, but that sphere is not in a public exhibition. It is a strictly medical matter, and in future the proprietor of this apparatus will be well advised to restrict his publicity to a medical public. It is hardly necessary to add that the jury gave their verdict in favour of the defendant.

Instruction in Tropical Diseases.

AT the festival dinner of the "Dreadnought" Seamen's Hospital Society, which took place last week at the Hotel Cecil, Mr. Chamberlain emphasised the fact that in the great work of civilisation and government our greatest enemy is not the hostility of the natives, nor the physical difficulties inseparable from residence in countries in which primeval nature still holds full sway, but rather the attacks of deadly diseases which weaken where they do not kill, and carry off many of the ablest and most energetic of our countrymen who carry the flag into these distant parts. He pointed out that it is not so much a question of mere hygiene, though this is not to be despised. What is required is a body of trained practitioners and, above all, of trained observers and investigators, who shall make the subject their own, and gradually wrest from Nature the secret of affording immunity against, and cure for, the various murderous diseases which render many otherwise eligible parts of the globe uninhabitable for human beings.

A Liverpool Hospital Scandal.

SINCE we alluded to this discreditable affair in our last issue, the donors and subscribers of the Liverpool Cancer and Skin Disease Hospital have met and passed a resolution proposed by the chairman, "that the report of the Special Committee be approved; and that Drs. Taylor and Whitford be removed from the office of honorary surgeons to the hospital." An amendment to this was proposed by a member, "that the subscribers and donors being dissatisfied with the result of the Committee's investigation, the Lord Mayor be appealed to and requested to appoint a committee to investigate the matter raised in the report." One would reasonably conclude that such an amendment was the most honourable and conclusive course to pursue in order to escape further criticism, and to close a scene that has now become repulsive with charges and recriminations, and thoughtful men will regret with us that this was not adopted. Our surprise is intensified by the chairman's preface to the resolution to the effect that certain letters were not in evidence while the sub-committee was investigating the management! This is an awkward statement. Is there not other information still wanting which an independent inquiry would discover? Another bad feature was noticeable in the voting: forty-five voting for the proposition and thirty-three for the amendment. Of the forty-five who voted for the proposition thirty-six were stated to have qualified as governors ten days before the time of meeting at the minimum qualification. This is a magical coincidence and phenomenal if true, reflecting the utmost discredit on those whose sole aim should have been the assurance of offering every opportunity for a disinterested inquiry and the restoration of order, peace, and confidence in the institution. We are not yet without hope that the managers will accept an independent inquiry and free themselves of the odium that still hovers round the whole transaction.

Food and Drug Adulteration.

THE fierce tussle which has been going on in the Grand Committee on the Adulteration Bill is nearly coming to an end. The contending parties may be divided into three camps; first, the adulterators who want leave to incorporate as much margarine in socalled butter, as much starch in cocoa, as much water in real butter, and so with other commodities as will pay them best; second, the home producers who are striving with all their might to boycott foreign produce by preventing margarine being coloured to look like butter, or preventing foreign meat or other produce being sold as home stuff; third, the purists, represented by the Government, who desire to protect the public against both these parties. The only important point which remains for decision is whether an invoice produced in court shall protect the immediate vendor against prosecution. It is the law, at present, that the shopkeeper selling an adulterated article shall be held innocent if he can present to the court a warranty from the person from whom he bought the article-That provision has seldom been operative, because either the shopkeeper knew perfectly well that the article was adulterated, and asked no questions because he wished to sell it cheap, or because the producer objected to give anything in the way of a written warranty, knowing that, if prosecuted, the shopkeeper could fall back upon him for damages. Consequently the average shopkeeper is never able to produce any better evidence than an invoice, and the purists strive to have such document accepted as a legal guarantee. The sanitary authorities are not favourable, because such decision would push them back, in their endeavour to force the Act, upon unknown persons whose names and addresses they cannot know at first, and who often are out of the legal jurisdiction.

Cat's Meat Sausages.

A CASE tried last week by the North London Police Court magistrate opens up various considerations of the deepest gravity as affecting the health of the people. To put the matter in a few words a sausage maker and a cat's meat dealer, both in the wholesale trade, were charged with having deposited and sold unsound meat for human food. The collusion and the fact were abundantly proved, and from the evidence it appeared that meat not good enough for cats was considered fit for sausages. Both defendants were fined £50, with the alternative of two months' imprisonment. Considering the vast amount of untraceable and deadly disease that stalks through the metropolis, we venture to consider an offence of this kind one of the most criminal that could be committed. Everyone who dies from eating such a sausage as that vended by these rascals—and such deaths must be manifold—is to all intents and purposes murdered by a reckless tradesman for the sake of a few pence blood money. Needless to say these wretched conspirators paid their fines, and doubtless went home chuckling to their suburban villas. The only fault we have to find with the magistrate's verdict is that there should have been no alternative to the fine, which should have been inflicted in addition to the imprisonment. Fresh legislation of a Draconian character is needed to repress these constantly recurring bad meat offences. Some years ago the Daily Chronicle emitted a famous Philippic against the filthy practice of eating sound horseflesh. What has it to say about this fraudulent foisting of decayed horseflesh upon Her Majesty's lieges?

Joint-Stock Doctoring.

FURTHER inquiry into the genesis of this new company, "Bland Limited," established in Dublin for the purpose of carrying on joint-stock doctoring by any number of unqualified persons under the cover of one or two registered practitioners, informs us that the company is a syndicate established to take over the business of Leonard and Co., which carries on several branches in Dublin, and is believed to be practically under the control of Mr. MacWalter, a qualified practitioner. The scheme of the syndicate is undoubtedly a strong one from a commercial point of view, but if the Lord Chancellor passes the Bill for the control of joint-stock doctoring, which Bill

now lies on the table of the House of Lords, there will be an end to the company, as also there will be if the General Medical Council decrees the covering of such method of practice by a registered practitioner to be "infamous conduct in a professional respect."

The "Jigger" or "Chigger."

THE Government of Bombay has approved measures having for object to prevent the introduction of the disease known as the "Jigger," or, as it is sometimes written, "Chigger." The disease, it will be remembered, is produced by a parasite known to science as Pulex penetrans. It usually attacks the feet, the female burrowing under the skin, where it gradually enlarges to the size of a pea. In the earlier stages detection is almost impossible, the very minute black spot denoting the presence of the insect being easily overlooked. Later on, as the enlargement, due to the development of numerous eggs, increases, a slight itching or pain is felt, and the skin is seen to be discoloured. When fully developed, the sac containing the egg ruptures, the eggs escape and develop into the mature insect. The sac can be wholly removed, but the operation is a difficult and delicate one. When the sac is ruptured a very serious inflammation, proceeding to disease of the bone, is sometimes set up.

The Coming Annual Meeting of the Irish Medical Association in Cork.

So far as the arrangements for the annual meeting of the Association have been completed they will be as follows:-The meeting will open in the Examination Hall of the Queen's College on Tuesday, June 20th, at 3.30 p.m., and at the conclusion of the meet. ing the President and Council of the College will entertain the members. In the evening the dinner of the Association will be held at the Royal Victoria Hotel at 7.30 p.m. On Wednesday, the 21st inst., the profession in the county and city of Cork will entertain the members on an excursion to the harbour to view the Regatta, and luncheon will be served to them. We understand that the profession in Cork has invited many persons of distinction and official importance to the annual dinner. It is hoped that arrangements may be made with the several railway companies for the issue of return tickets to members attending the meeting at single fares.

Salaries of Medical Officers of Health in Dublin.

THE Guardians of the South Dublin Union have given formal official notice to the Medical Officers of Health within their jurisdiction that they will not, in future, pay the salary of £25 a year to each, and the doctors are referred to the Borough Council, i.e., the Dublin Corporation, for their sanitary emoluments. The Guardians of the North Union have not yet followed this lead, and it is doubtful that they will do so until their legal liability is put beyond question. Heretofore, the dispensary doctors have, in their capacity of

Medical Officers of Health, been recognised as being as much the functionaries of the Corporation as of the Union, but they have received their salaries without question from the guardians, and these salaries have been, we believe, paid exclusively out of the rates. Whether the new Local Government Act has made a change in this respect we are not at present able to say.

Infectious Disease Notification.

THE Bill to extend the compulsory notification system to all sanitary authorities throughout the kingdom got its second reading in the Lords last week, and may be now considered to be the law of the land. There is satisfaction in the reflection that no power can compel such authorities to undertake the expense and trouble of the system if they do not like to do so. They can simply ignore the system, as has been done in scores of districts in which, in accordance with the fashionable craze, the adoption of it was enacted many years ago.

The Disinfection of Empty Apartments.

THE Society of Hygiene of the Seine has had under its consideration this question. It appears that tenants of apartments in which infective disease has existed have, on many occasions, vacated the premises and gone beyond reach without letting anyone know that the rooms were infected, the consequence of which was that new tenants entered into possession and, in some instances, immediately caught the disease. A change of law was proposed which would make the outgoing tenant amenable for this concealment.

The Council Election at the Irish College of Surgeons.

In addition to the names of Messrs. Story, Patteson, Morrison, and MacCausland, mentioned in another part of our issue as candidates for seats on the Council at the forthcoming election, we record the names of Mr. Dallas Pratt, of Jervis Street Hospital, and Mr. Robert Henry Woods, Throat and Ear Surgeon to the House of Industry Hospitals.

Death of the "Sleeping Boys."

BOTH the Congo boys who have been in the Charing Cross Hospital for the last three months, suffering from "sleeping sickness," are now dead. The disease to which they have succumbed is common enough in certain parts of Africa, but the parasite—a variety of filaria sanguinis hominis—only attacks coloured people.

THE action brought by the Medical Defence Union for the recovery of a penalty against a retail chemist called Tempest, at Pontefract, was heard last week, he being charged with falsely representing himself to be a doctor of medicine. The case had been tried at a previous sitting, but the jury failed to agree. It was contended that the defendant had only acted within his rights as a registered chemist in giving people medicine, although it has been laid down

that to feel a person's pulse and to look at his tongue before giving medicine constitutes an infringement of the Apothecaries' Act. We regret to say that the jury gave a verdict in favour of the defendant. This is only another example of the ambiguity of the law on the subject of unqualified practice, and of the difficulty of enforcing it even when the main facts are not disputed.

A MELANCHOLY inebriate at Birmingham last week swallowed a quantity of laudanaum with suicidal intent, and the task of keeping him awake after the administration of the usual remedies fell to a constable, who took his duty au serieux. So vigorously did he carry out his mandate that, by the time he was relieved, he had scarcely a button left on his tunic or shirt, and everyone knows that the buttons are the most sensitive parts of a policeman's attire. We gather that the patient resented being shaken up at intervals, and retaliated by shaking the constable, also at intervals.

A HOSPITAL nurse at Birmingham, who, though summoned as a witness, failed to put in appearance at an inquest, sending as excuse that she was engaged at a serious operation, was last week fined £5, on the ground that her place in the operating theatre might very well have been taken by some other nurse. This is right as far as it goes, but it is to be hoped that the hospital authorities will intervene to disarm the coroner or else pay the penalty.

THE Jodrell Professorship of Zoology in University College, London, will be vacant at the end of the present session in consequence of the resignation of Professor Weldon. Applications must be sent in before June 5th.

PERSONAL.

PROFESSOR R. E. JEBB, M.P., has consented to distribute the certificates and prizes at King's College, London, on July 12th.

THE late Dr. C. J. Hare has bequeathed £500, free of legacy duty, to the endowment fund of the Royal College of Physicians, of London.

MISS ROBERTS has presented to the Royal College of Physicians of London a portrait, by G. T. Watts, R.A., of her father, the late Sir William Roberts.

SIR HENRY FREDERICK NORBURY, M.D., K.C.B., Inspector-General of Hospitals and Fleets, and Director-General of the Medical Department of the Navy, has been placed on the retired list.

MR. HY. GWYNNE LAURENCE, M.B.Lond., came out first in the Honours List for Medicine of the University of London last week, taking the Gold Medal and Scholarship of £100, and first class in obstetrics.

DR. J. BUCKLEY BRADBURY, Downing Professor of Medicine in the University of Cambridge, will deliver the Croonian lectures in June on "Some Points in connection with Sleep, Sleeplessness, and Hypnotics."

DE. J. B. COLEMAN, Visiting Physician to the House of Industry Hospitals, Dublin, and Dr. Francis Charles Martley, lately of St. Mary's Hospital, London, have been elected to be Fellows of the Royal College of Physicians, Ireland.

ME J. B. STORY, surgeon to St Mark's division of the Royal Victoria Eye Hospital, Dublin, (Professor), and recently examiner in ophthalmology in the College has announced his candidature for a seat on the Council of the Royal College of Surgeons of Ireland.

The order of the Medjidieh of the second class has been conferred by the Khedive of Egypt on Surgeon-General William Taylor, C.B., M.D., of the Army Medical Staff, and the same order of the fourth class to Lieut-Colonel Arthur Thos. Sloggett in recognition of service rendered in the Soudan during the recent campaign.

Scotland.

FROM OUR OWN CORRESPONDENT.

TUBERCULOSIS PREVENTION MOVEMENT IN GLASGOW. —The Glasgow Southern Medical Society has just concluded a lengthy discussion on "The Prevention of Tuberculosis." In view of the widespread interest in the matter and the likelihood of definite action being taken by the citizens shortly, it was decided that the discussion should not be confined to members of the medical profession, but that all classes likely to be affected by new regulations should be invited to take part in the discussion. Consequently there was a very representative body present of all kinds—farmers, health officers, veterinary surgeons, &c. The conclusions arrived at may be shortly stated as follows: - The mortality in this country from tuberculous disease is greatly on the decrease, that the disease is preventible, and much can be done by the co-operation of the public and the medical profession, if not to entirely exterminate it, to greatly lessen its ravages. It is a true germ disease and not hereditary as was formerly supposed. That it is communicable by the milk of cows, still more so from man to man, the chief danger being infective expectoration. Bad hygienic conditions tends to its propagation. It is proposed that there should be formed in Glasgow a society for the spread of knowledge regarding tuberculosis, and the means to be used for stamping it out. Every assistance is to be given to the sanitary authorities, and the City Improvement Trust should see that narrow lanes and back tenements be removed so as to admit more sunlight into places which are now in perpetual darkness. If the suggestions pointed out by the meeting be carried out, even to a minimum degree, we shall at last find Glasgow to be a veritable Hygiea.

MEDICAL OPPOSITION TO NOTIFICATION IN AYRSHIEE.—At the last meeting of the Northern District of the Ayrshire County Council, the Sanitary Inspector reported that several medical practitioners throughout the district had intimated that they would not sign the certificate adopted at the district meeting, for removal of cases of infectious diseases to the hospital. It was agreed to ask the opinion of the Local Government Board and county clerk as to whether the form adopted was within the provision of the Act.

A MEDICAL ELECTION DISPUTE.—The village of Eaglesham, not far distant from Glasgow, is at present much exercised over a muddle which lately occurred in the business of the Parish Council. About two months ago Dr. Pollock, the medical officer, resigned his appointment, Dr. Stuart, of Hamilton, bought the village practice, with the expectation that he would receive the public appointment, he being the only medical man in the village. The Parish Council met on March 25th to make the appointment, when Dr. Robertson, of South Harris, was

nominated along with Dr. Stuart. Six members attended the meeting, three of whom, not including the chairman pro tem., supported Dr. Robertson. The chairman, on being asked for whom he would vote, made reply which conveyed the impression to the clerk that he supported Dr. Stuart. A minute was accordingly prepared to the effect that Dr. Stuart was duly appointed, which was duly signed by the chairman after being read to the meeting. Dr. Stuart was duly notified of his appointment, but it now turns out that the chairman was under the impression that when he signed the minutes he was doing so in favour of Dr. Robertson, whom he wished to support. Dr. Robertson was also in due course informed of his success. The result is legal opinion is being taken to settle the matter.

GLASGOW MEDICO-CHIRURGICAL SOCIETY .- The following office-bearers have been elected for session 1899-1900: President, Mr. H. E. Clark. Section of Medicine—Councillor, Dr. J. A. Allan; Secretary, Dr. Hinshelwood. Surgery—Councillor, Mr. Maylard; Secretary, Dr. J. H. Nicoll. Pathology—Vice-President, Dr. J. Lindsay Steven; Councillor, Dr. Teacher; Secretary, Dr. R. M. Buchanan. Obstetrics—Vice-President, Dr. Edgar; Councillor, Dr. Gibson; Secretary, Dr. Balfour Marshall; Treasurer, Dr. Barclay Ness; Editorial Secretary, Dr. W. B. Jack; and General Secretary, Dr. W. K. Hunter.

Parliamentary Acws.

THE LAW OF CONSTRUCTIVE MURDER was admitted by the Home Secretary to require amendment, but the matter, in his opinion, presents such grave technical difficulties that the Government do not see their way to introduce a Bill with that object in view themselves, or to offer facilities for such a Bill, during the present session. In the meantime, the judges have been asked to communicate their views on the matter.

PRESERVATIVES IN FCOD.—In answer to a question, the President of the Local Government Board said it had been decided to appoint a departmental committee to

inquire into the use of preservatives in food.

VENEREAL DISEASE AT GIBRALTAR.—In reply to a question in the House it was stated that during the five years ending 1897 the admissions to hospital for venereal disease among the garrison of Gibraltar averaged 290 per annum per thousand, as against 152 at Malta and 170 among the home troops. The average daily number in hospital was 28.3 per thousand, as compared with 13.5 at Malta and 15 at home.

THE MIDWIVES BILL has again been postponed, and was put down for yesterday (Tuesday). Unless it then reached a second reading its fate is sealed for the present

session.

VIVISECTION.—In answer to Mr. Paulton, the Home Secretary stated that the special certificates issued to persons desirous of performing certain experiments on living animals were merely to authorise them to keep the animal alive after the influence of the anæsthetic had passed off when killing the animal would necessarily frustrate the object of the experiment, and they provided that the animal should be killed so soon as that object had been attained. He added that he would certainly not allow the issue of any certificate for experiments involving dissections or painful operations without the fresh use of anæsthetics. He declared his continued adhesion to the paragraph having reference to the exemption from the obligation to give anæsthetics, pointing out that these certificates were only given for such operations as inoculations and hypodermic injections which were of a comparatively painless character.

UNQUALIFIED DISPENSERS.—In reply to a question by Major Rasch as to the grounds on which the General Medical Council had declared accidents due to the employment by medical men of unqualified dispensers were rare, Sir J. Gorst said that the infrequency with which such accidents were reported to the Privy Council confirmed the opinion that they were very rare, and on this account the Privy Council had not thought it necessary to ask the Medical Council for any further information.

Correspondence

We do not hold ourselves responsible for the opinions of our

THE ANTI-VIVISECTION GALA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You think that I and my fellow anti-vivi-sectionists have a blind spot on our mental retine, while we think that you and your vivisectionists suffer from

chronic glaucoma.

It is not a question as to whether science has benefited by experiments on living animals or not, that is not the issue at all, for "science" is a word which is erroneously rendered. The real question is whether or not the arts of medicine and surgery have not been so consistently marked by experiments in themselves most abhorrent, that so much evil has been done and so little good, that they should be given up entirely. Everybody admits that such method of research is so untrustworthy as to be outside the use of surgeons altogether. The last important convert to this view is my much-esteemed friend, Mr. Frederick Treves, concerning the surgery of the intestines.

Dr. Vivian Poore, in his recent lectures, tells us that the thing medicine has greatest reason to be proud of is the banishment of typhoid fever, and this has been accomplished absolutely, in spite of the erroneous conclusions derived from experiments on animals. Will you venture to call the scandalous story of tuberculin a scientific triumph? Is the absolute failure of Pasteur's anti-rabic serum a therapeutic victory? Is the cold shoulder already given to antitoxin something very scientific and a matter of pride to our vivisection science? You really have incurable chronic glaucoma.

I am, Sir, yours truly,

LAWSON TAIT.

195 Newhall Street, Birmingham.

It is idle to bandy argument with a polemic who prefaces the most highly contentious statements with the bland "everybody admits." We are curious to know how far "my much-esteemed friend Mr. Frederick Treves" approves of Mr. Tait's throwing his mantle over him in this patronising manner.—Ed.]

Literature.

DR. SOUTHWOOD SMITH—A RETROSPECT. (a)

The author gives a picturesque account of the life of her grandfather—1788-1861—not in a series of tableaux, as is so often done, but in a veritable living-picture which irresistibly carries the reader's interest from start to finish. Brought up to become a minister of a body of Calvinistic Dissenters, at eighteen, from conscientious scruples, he gave that career up and was cut off by his family for ever. Left a widower with two daughters at twenty-four, he entered Edinburgh University and devoted himself to medicine; at this time he wrote "Illustrations of the Divine Government." Qualifying he went to Yeovil, where he took charge of a congregation, and, at the same time, practised medicine. Soon, how-ever, he was drawn to London, and was appointed physician to the London Fever Hospital; there he remained until his retirement from public life on the disappearance of the Board of Health in 1854.

The chief works of Dr. Southwood Smith's life were drawing public attention to the preventibility of fevers, the agitation that led to the Factory Acts, and the abolition of child and woman labour in coal mines; Dr. Smith also took a chief part in the erection of the first modeldwellings for the working classes, and established a sanatorium for paying patients which was the forerunner

of the present home hospitals. Probably no book outside Charles Kingsley's writings

(a) "Dr. Southwood Smith: A Retrospect," By his Grand-daughter, Mrs C. L. Lewes. Edunburgh and London: William Blackwood and Sons. 1898. Pp. xii -169.

gives a better picture of the splendid work that the sanitarians of this century have accomplished.

TWENTIETH CENTURY PRACTICE (a)

THE editor of this magnificent series of volumes of instuction for the practitioner of the now rapidlyapproaching new century is more and more to be congratulated on the excellent standard of uniformity which has been maintained throughout, and on the regularity with which the successive items have been placed at the disposal of the professional public. The theses of which the fourteenth volume is composed include "Scarlet Fever" and "German Measles," by Dr. Frederick Forchheimer, Professor of Physic and of Diseases of Children in the Medical College of Ohio, Cincinnati; "Measles" and "Glandular Fever," by Dr. Dawson Williams, of London; "Whooping-Cough," by Dr. Joseph Williams, of London; "Whooping-Cough," by Dr. Joseph O'Dwyer and Dr. N. R. Norton—both of New York; "Cholera Infantum," by Dr. A. Jacobi, of New York; "Cholera Nostras" and "Asiatic Cholera," by Dr. Theodor Rumpf, Director of the New General Hospital in Hamburg, formerly Professor at the University of Bonn, and Director of the Polyclinic at Marburg; Bonn, and Director of the Polyclinic at Marburg; "Dengue," by Sir Joseph Fayrer, Bart.. F.R.S.; "Beriberi," by Dr. A. A de Azevedo Sodré, Professor in the Faculty of Medicine of Rio de Janeiro, and editor of O Brazil Medico; "Miliary Fever," by Dr. A. Netter, Physician to the Hopital Trousseau, Paris, and Professeur Agrege in the University of Paris; and "Malta Fever," by Major David Bruce, M.B., C.M., of Pietermaritzburg, South Africa.

Among the items included in this rich mine of clinical and scientific information, we have studied with special interest the article on "Cholera," by Dr. Rumpf, who has here placed before the readers of the "Twentieth Century Practice" the vast store of experience which he accumulated during observations of the still recent epi-demics of that terrible disease in Hamburg. We will not pause for a moment to criticise this splendid contribution to professional literature, but recommend it most etrongly to the perusal of every practitioner of medicine. We will also here remark that the subject of "Cholera Infantum," to which so little space is devoted in most of our text-books of medicine, is here treated in one of the ablest articles of the volume by Dr. A. Jacobi.

Another article which we have studied with peculiar interest is that on "Beri-beri," by Dr. Sodre. This disease, which we had till lately been accustomed to look upon as a pure exotic, has recently been transplanted on so large a scale to some of our own British-and more especially Hibernian-institutions, that this very able contribution by the skilled and experienced hand cannot fail to attract special attention.

We think it unnecessary to repeat at any length the high opinion that we have formed of this excellent volume; we will conclude by observing that it is thoroughly worthy of its predecessors.

POISON ROMANCE.

" Poison Romance and Poison Mysteries," by C. J. S. Thompson (The Scientific Press, Limited), is a decidedly interesting reading. It reads more like a fairy story than a treatise on toxicology. The author deals in a positively amusing way with the poisons of antiquity, royal and historic poisoners, poisoning plots, and all such kinds of fascinating subjects. He gives us the true history of the Maybrick case, the case of Dr. Lamson, the Bravo mystery, and of many remarkable criminal trials, the details of which are summed up in a masterly manner. The author is evidently quite at home in this gruesome department, and knows how to present his material in a readable form. He is a true novelist, who has taken toxicology as a basis. A work of this description appeals very largely to the non-medical public, and we should not be at all surprised if Mr. C. J. S. Thompson blossomed out into a popular writer of some repute. He has struck an original vein, and it will be his own fault if he does not work it.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list :-

AILLIERE, TINDALL, AND Cox (London and Paris).

On Fractures and Dislocations. By Professor Helferich, of Griefswald. With 68 full-page plates and text, authorised translation (Balliere, Tindall, and Cox's "Hand-Atlas Series"). Price 15s. net.

The Analysis of Food and Drugs. Vol. II.—The Chemical and Biological Analysis of Water. By T. H. Pearmain and C. G. Moor, M.A.Cantab., F.I.C. Pp. 172. Price 5s. net.

CASSELL AND Co., Limited (London).

Hygiene and Public Health. By Arthur Whitelegge, M.D., F.R.C.P. Pp. 538, price 7s. 6d.

Materia Medica and Therapeutics. By J. Mitchell Bruce, M.A., Aberd., F.R.C.P.Lond. Pp. 609. Price 7s. 6d.

J. AND A. CHURCHILL (London).

A Short Practice of Midwifery. By Hy. Jellett, M.D., F.R.C.P.I., with a preface by W. J. Smyly, M.D., F.R.C.P.I. Second Edition. Pp. 281. Price 6s.

A Class-book of Practical Physiology. By De Burgh Birch, M.D., F.R.S. Ed. Pp. 272. Price 6s. 6d.

DAWBARK AND WARD, LIMITED (London).

The Natural Waters of Harrogate. By F. W. Smith, M.D. Pp 102. Price 1s.

H. J. GLAISHER (London).

Clinical Lectures on Neurasthenia. By Thos. D. Savill, M.D. Pp. 144. Price 5s. net.

E. Gould and Son. Limited (London).

Viscum Album, the Common Mistletoe as a Drug. By George Black, M.B.Ed. Price 1s.

CHAS. GRIFPIN AND COMPANY, LIMITED (London).

Practical Sanitation. By George Reid, M.D., D.P.H. Pp. 344.

KEGAN, PAUL, TRENCH, TRUBNER, AND Co. (London).

Victor von Richter's Organic Chemistry. Edited by Prof. R. Auschutz. Translated by Edgar F. Smith, Professor of Chemistry, Univ. Pennsylvania. Vol. I. Pp. 625.

J. P. LEGG AND Co. (London).

Hygiene of the Mouth. By R. Denison Pedley, F.R.C.S.Ed. L.D.S. Eng. Pp. 94. Price 2s. 6d.

H. K. LEWIS (London).

Exploration of the Urethra and Bladder. By M. Tuchmann, M.B.C.S., M.D., Wurzburg. Pp. 56. Price 5s.

The Middlesex Hospital Reports for the year 1897. Pp. 392.

Price 2s, 6d. net.

A Manual of Surgical Treatment in six parts. By W. Watson Cheyne, M.B., F.B.C.S., F.B.S., and F. F. Burghard, M.D. Lond., F.B.C.S. Part I. - General Surgical Diseases. Pp. 285. Price

E, AND S. LIVINGSTONE (Edinburgh).

The Students' Materia Medica. By Grace H. Giffen, L.B.C.P.Ed-Pp. 96. Price 2s.

LONGMANS, GREEN, AND Co. (London).

Royal University of Ireland. Calendar for 1899.

MACMILLAN AND Co. (London).

A System of Medicine by many Writers. Edited by Thos. Clifford Allbutt, M.D., F.R.C.S., F.R.S. Vol. VI. Pp. 944. Price 25.

SIR I. PITMAN AND SONS, LIMITED (London).

Some Diseases of the Rectum and Anus. By Sir Wm. Thomson, F.R.C.S.I. Pp. 56. Price 2s. 6d.

THE SCIENTIFIC PRESS, LIMITED (London).

Burdett's Official Nursing Directory, 1899. Edited by Sir Hy. Burdett, K.C.B. Pp. 651. Price 5s.

SPOTTISWOODE AND Co. (London).

The Medical Register for 1899. Under the direction of the General Medical Council.
The Dentists' Register for 1899. Under the direction of the General Medical Council.

JOHN WRIGHT AND Co, (Bristol).

The Medical Annual and Practitioner's Index for 1899. Pp. 720, Price 7s, 6d, net.

Animal Simples approved for Modern Uses and Cure. By W. T Fernie, M.D. Pp. 564. Price 6s. Golden Rules of Medical Practice. By Arthur H. Evans, M.D. Lond., F.R.C.S. Pp. 71. Price 1s.

⁽a) "Twentieth Century Practice; an International Encyclopeedia of Modern Medical Science by Leading Authorities of Europe and America." Edited by Thomas L. Stedman, M.D., New York City. Vol. XIV. London: Sampson, Low, Marston and Co. City. 1898.

Aew Instruments.

"MAGENNIS'S MIDWIFERY SURGICAL INSTRUMENT."

Use.-1. This instrument by cutting and, at the same time, compressing both the cut ends of the umbilical

cord will supply the place of the scissors and ligatures now used in

midwifery practice.

2. By the old method of ligaturing, the accoucheur, after tying with the first thread, stripes the umbilical cord along, and then requires some one to hold and compress at the particular place to which he has driven the blood, while he applies the second ligature. If he did not do this, the moment the umbilical cord is cut the bloods spurts over the bedclothes, &c.

3. When the clamp is applied the accoucheur is at liberty to attend to either the mother or child.

4. If the accoucheur is not satisfied that the ends are sufficiently

compressed the application of the clamp makes the tying easy and clean.

Mode of Using. -When pulsa-tion in the cord has ceased it is be placed to between the blades of the clamp resting on

the plain side, the knifed side is then pressed firmly down, and the catch retains it in position. Messrs. Arnold and Sons, London, are the makers.

NEW PESSARY HOLDER.

THE introduction and proper adjustment of a Hodges' Pessary has been always a puzzle to some practitioners, and it has now become fashionable to decry the use of this most valuable appliance for the reasons above stated.

By the use of the instrument depicted (made for Dr. Alexander Duke, of Cheltenham, by Messrs. Arnold and Sons, Smithfield), the proceeding will be much facilitated, the necessary manipulation being materially assisted by the leverage afforded by the holder.

It is hardly necessary to remark that the uterus should be replaced as nearly as possible in its normal position before the proper sized pessary is placed in situ. The neglect of this and the idea that the pessary will do all, has decidedly helped to bring it into disrepute. A properly fitted support will in every case give the patient relief, and thus gain her confidence towards subsequent treatment.

Volunteer Medical Association.

THE annual dinner of this Association took place on Wednesday, the 10th inst., under the presidency of Colonel O'Farrell, R.A.M.C., in the unavoidable absence of Major-General Trotter. About fifty of the members and their friends were present. Among the guests were Colonel Sir Howard Vincent, Colonel Edis, and Lieut. Colonel Daniel.

Medical Aews and Pass Lists.

The Royal University of Ireland.

A MEETING of the Senate was held on Thursday.

May 11th, 1899, at 11 o'clock.

Present: Sir Thomas Moppett, Pro. Chancellor, in the Hamilton, Sir Wm. Thomson, Dr. Leebody, Mr. Starkie, and Dr. Meredith and Dr. McGrath, secretaries.

A communication was received from the Clerk of Convocation notifying the election of Dr. T. Walton Browne as a member of the Senate. A resolution was adopted recording the regret of the Senate at the death of the late Right Hon. C. T. Redington, vice-Chancellor of the University. The election of the Vice-Chancellor was postponed to next meeting.

The results of the Spring Medical Examinations were submitted and approved. [Declaring University education in Ireland unsatisfactory.—Ed., Medical Press.]

The debate upon O'Conor Don's motion adjourned

from last meeting was resumed, and by leave of the Senate the amendment and original motion were with-

It was resolved that a studentship in Celtic language and literature be offered for competition in 1903. It was ordered that the list of scholars elected in 1897 be amended by inserting as first of the second class scholars in Modern Literature:-Helena Walsh, Lo reto Convent, North Great George's Street, Dublin.

An address of congratulation was adopted to Sir George Gabriel Stokes, Bart, LL.D., Sc.D., upon his attaining his fiftieth year as Lucasian Professor of Mathematics

at Cambridge University.

A communication was received from the Conjoint Examining Board in England intimating that such alterations had been made in their regulations as would place the medical students of this University upon the same footing as regards the examinations of that Board as the medical students of other Universities.

The Medical Society of London.

THE conversazione of this Society is the first leaf to fall from the tree of medical science, and marks the approaching autumn of the medical year. On Monday evening the spacious and handsome rooms of the Society in Chandos Street were crowded to repletion, and even a trifle beyond, by Fellows who had assembled in their hundreds to listen to the Oration, which was delivered in his best style by that versatile genius, Mr. Alban Doran, who chose for his subject "Shakespeare and the Medical Society." The orator gave abundant proof of an intimate acquaintanceship with the most out-of-theway corners of the great dramatist's literary monument, and the quotations with which his discourse was larded served him as so many salient points on which to hang remarks of exquisite drollery which excited bursts of laughter, alternating with rounds of applause as, with a light but dexterous wit, he drove home his pungent reflections. After the oration, which was preceded by a reception by the President, Mr. Edmund Owen, the conversazione proper began, the hum of conversation being masked by the strains of the Bijou Orchestra and sanctified by the incense burned on the shrine of the Goddess Nicotine.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held on the 28th ult. at 429, Strand, London, W.C. There were present Dr. de Havilland Hall (in the chair), Dr. J. B. Ball, Dr. G. E. Harman, Mr. W. J. Stephens, Dr. F. R. Mutsh, Dr. W. Knowsley Sibley, Mr. J. Brindley James, Dr. F. J. Allan, Dr. J. W. Hunt, Mr. F. Swinford Edwards, Mr. Edward Bartlett, and Dr. Walter Smith. The annual report for 1898 was agreed upon. It shows that the business of the Society has largely increased during the year. The Sickness Fund grew from £53,472 to £58,211, although

from this fund no less than £6,175 was disbursed during the twelve months to members incapacitated by illness. The quinquennial valuation report was also considered. The valuation made by the Secretary, Mr. F. Addiscott, F.I.A., and certified by the Consulting Actuary to the Society, Geo. S. Crisford, Esq., F.I.A., Actuary of the Rock Life Assurance Company, and one of the Public Valuers under the Friendly Societies' Act, shows that the Society possesses a surplus fund of between six and seven thousand pounds. This, if applied, as at the previous valuation in 1894, as a cash bonus, will allow of a return of 10 per cent. upon all sickness benefit premiums paid during the Quinquennium. These reports will be presented to the members at the annual general meeting to be held on 24th inst., at 5 o'clock, at the House of the Medical Society of London, 11, Chandos Street, Cavendish Square, London, W. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

West Kent Medico-Chirurgical Society.

THE Seventh Meeting of the Forty-Third Session, 1898-99, was held at the Boyal Kent Dispensary, Greenwich Road, on Friday, May 5th, 1899, at 8.45 p.m., Morgan Dockrell, Esq., M.A., M.D., President, in the chair, when the following was the business of the evening:—Dr. Morgan Dockrell delivered his Presidential n "General Health as a Factor in Skin After the conclusion of the President's Address on Disease." Address a very enjoyable smoking concert was held. Among the artistes who kindly gave their services were Messrs. Courtice Pounds, Carl Brandt, Walter Grace, F. H. Cheesewright (vocalist), Charles Frondi (musical sketches), H. Wharton Wells (piano), and Dr. Boyd Page (conjuring).

Royal College of Physicians of Londen.

AT a meeting of the Royal College of Physicians, held on Thursday, the President, Dr. W. Selby Church, occupying the chair, the following gentlemen were admitted Fellows of the College:—Dr. S. A. M. Copeman, London; Dr. W. J. Hadley, London; Dr. H. Handford, Nottingham; Dr. P. Horton-Smith, London; Dr. C. Ogle, London; Dr. A. Ransome, Bournemouth; Dr. W. H. B. Rivers, Cambridge; Dr. W. J. R. Simpson, London; Dr. W. V. Snow, Bournemouth; and Dr. H. R. Spencer, London.

Mortality in Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Calcutta 40, Bombay 104, Paris 20, Brussels 16, Amsterdam 12, Rotterdam 18, the Hague 13, Copen-12, Moscow —, Berlin 19, Christiania 15, St. Petersburg 25, Moscow —, Berlin 19, Hamburg 17, Dresden 20, Breslau —, Munich 26, Vienna 22, Prague 32, Buda-Pesth 24, Trieste 33, Rome 14, Turin (eleven days) 23, Venice 39, New York (including Brooklyn) —, Philadelphia 21 delphia 21.

New Process of Cleaning Bed Linen.

In a circular, the surgeon-general of the Germanarmy, Golar, in Berlin, calls the attention of the heads of the garrison hospitals to a new cleaning method, which is to be employed in future, as thorough experiments have proved it to be of advantage. By this method, petroleum is added to the water besides soap and soda, taking as many grammes of it as there are litres of water used; e.g., 30 grammes of petroleum to 30 litres of water. This admixture of petroleum does not only admit of an easier cleaning, as well as less tear and wear on the linen, but the wash also retains its colour, is thoroughly disinfected, and the expenses are considerably reduced by a saving in soap.—Scientific American.

The Oxygen Home.

PRINCESS LOUISE, Marchioness of Lorne, attended the annual meeting of the Oxygen Home for the Treatment of Ulcers and Wounds by Oxygen Gas, 2, Fitzroy Square. Mr. Burdett-Coutts, M.P., chairman of the general committee, presided. Sir Francis Osborne, the hon. secre-

tary, read the third annual report, in which the com mittee recorded the continued success of the oxygen treatment. Since the home was opened, three years ago, 231 cases had been treated, and of these 172 had been cured. Of the 101 cases treated last year 66 had been cured. Dr. Granville Bantock seconded the resolution, which was carried. The Marchioness of Lorne visited the wards of the hospital before she left, and praised the admirable arrangements that were in operation. The outstanding liabilities of the home at the end of April amounted to £1,122.

London School of Medicine for Women.

WE are asked to announce that a dog show will be held on June 3rd at the London (Royal Free Hospital) School of Medicine for Women, Hunter Street, Brunswick Square. Only qualified practitioners, members of the teaching staffs at the Medical Schools, and medical students may exhibit. Twenty-six classes have been provided; three prizes are offered in each class, and a large number of special prizes have been offered. Captain Barry, Mr. E. W. Allen, Mr. G. R. Kuhl have kindly volunteered their services as judges. Entries will be received till Saturday next, May 20th. Schedules and entry forms may be obtained by applying to the secretaries at Hunter Street, and the committee hope that the medical profession will cordially support the enterprise, the proceeds of which are to be devoted to the building fund of the Womens' Medical School.

The Royal University of Ireland. Medical Degrees.

M.B., B.Ch., B.A.O. DEGREES.

M.B., B.Ch., B.A.O. DEGREES.

UPPER PASS. William Cahill, Qu. C., Cork: Bartholomew J. Hackett, Cath. Univ.; *Edmond McDonnell, Qu. C., Cork: *John W. D. Megaw, Qu. C., Belfast; Andrew Murphy, Qu. C., Cork; *Robert Steen Qu. C., Belfast. Those marked thus (*) may present themselves for honours.

PASS. Bichard Athern, Qu. C., Cork; Peter J. Burke, Cath. Univ., Patrick J. England, Qu. C., Cork: Francis S. Irvine, Qu. C., Belfast: Frederick C. McHee, Qu. C., Belfast; Hugh J. McNabb, B.A., Cath. Univ.; William O'S. Murphy, Qu. C., Cork; Robinson Officer, Qu. C., Belfast: William Paisley, Qu. Cs., Galway and Belfast and Univ. Edin.; William Rice, Qu. C., Cork; and Isobel A. Tate, Qu. C. Belfast:

M.D. DEGREE EXAMINATION.

Pass.—Mina. L. Dobbie, Lond. Sch. Med. Women; Joseph P. Trengley, Cath. Univ. and private Study.

THIRD MEDICAL EXAMINATION.

THIRD MEDICAL EXAMINATION.

UPPER PASS.—*Joseph G. Andersor, Qu. C., Galway; *James Gorman, Cath. Univ.; *Archibald G. Heron, B.A., Qu. C., Belfast; Oswald E. Jackson, Qu. C., Belfast: John C. McCarroll, Qu. C., Belfast; *David McMordie, B.A., Qu. C., Belfast; and *John O'Leary, Qu. C., Cork. Candidates marked * may present themselves for honours.

PASS.—William Barkley, Qu. C., Belfast; James P. Brady, Cath. Univ.; Frederick C. Bullen, Qu. C., Cork; John S. Cargin, Qu. C.; Belfast; Michael Crowley, Cath. Univ.; Frederick Garland, Cath. Univ., Timothy J. Hartigan, Cath. Univ.; John P. Higgins, M.A., Qu. C., Cork; Robert Kennedy, Qu. C., Belfast; Patrick Kerley, Cath. Univ.; Samuel McClure, Qu. C., Belfast; Patrick Kerley, Cath. Univ.; Samuel McClure, Qu. C., Belfast; John McCrea, B.A., Qu. C., Belfast; John A. Mills, B.A., Qu. C., Galway; James Park, Qu. C., Belfast; Chestnut Peacock, Qu. C., Belfast; Herbert C. Quirke, Mason Coll., Birmingham; Hugh B. Smith, Qu. C., Belfast; and William J. Thompson, Qu. C., Belfast.

University of Durham.

At the third examination for the degree of Bachelor in Medicine, during April, the following candidates have satisfied the Examiners:—

Honours-Second Class.

Born, Edward Turner, College of Medicine, Newcastle-on-Tyne. Wigfield. Frederick P., College of Medicine, Newcastle-on-Tyne. Pass List.

Pass List.

Alstrom, Hedda, London School of Medicine for Women.
Blandford, Laurence J., College of Medicine, Newcastle-on-Tyne.
Brown, George Burrows, College of Medicine, Newcastle-on-Tyne.
Braund, Henry, Guy's Hospital.
Cooke, Edleston Harvey, St. Thomas's Hospital.
Heslop, James Willie, College of Medicine, Newcastle-on-Tyne.
Jupp, Balph Tennyson, Mason College, Birmingham.
Morrison, John Wilson H., College of Medicine, Newcastle-on-Tyne.

Morrison, John Wilson H., College of Medicine, Newcastle-on-Tyne.

Mitchell, John Robert, College of Medicine, Newcastle-on-Tyne.

Macfadyen, John, College of Medicine, Newcastle-on-Tyne.

Perkins, Philip Meyler, St. Bartholomew's Hospital.

Rhodes, Thomas Basil, Mason College, Birmingham.

Raw, Stanley, College of Medicine, Newcastle-on-Tyne.

Swainston Eliot, College of Medicine, Newcastle-on-Tyne.

Stainthorpe, Wm Waters College of Medicine, Newcastle-on-Tyne.

Sidgwick, John Ernest, College of Medicine, Newcastle-on-Tyne.

Aotices to Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader, "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS .- Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before the type is broken up.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of The Medical Press AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through

WANTED, A MALE CHILD.

A CORRESPONDENT asks our opinion of the following printed circular letter, which bears the name of C. F. Knight, M.D., of Ludgate Hill, E.C., and is headed "Confidential." It seems to have been sent round broadcast:—

"An American lady of wealth, who wishes to adopt a male child, desires me to put her in communication with some one who can further her object,
"The boy should be between two and four years of age, of gentle birth (legitimate or illegitimate), of attractive appearance and promising character.

"The child's future would be assured: and it occurs to me that

"The child stuture would be assured: and it occurs to me that by communicating with a number of professional men, I may be enabled to find some one of them who would be glad to indicate a suitable boy."

* There is nothing actually unprofessional in the foregoing, however much one may question the desirability of a medical man engaging in this department of research.

MR. GUY C. ROTHERY.-Your communication will appear in an

me. Gut C. Rollson.—The only practical book on the subject within our knowledge is: "The Rontgen Rays in Medical Work," by Dr. David Walsh, Hon. Secretary of the Rontgen Ray Society.

Dr. W. M. J. will see the matter has been referred to in another

column.

DR. JOHN KHOIT.—We hope to have space for your paper on "Internal Derangement of the Knee-joint" in our next.

DR. D. C. S. will receive a private note so soon as the necessary inquiries have been made. We may say, however, in advance that we think our correspondent need have no doubt as to the result.

DUMAS AND THE PHYSICIAN.

DUMAS AND THE PHYSICIAN.

It is related of Dumas that he was one day introduced to a pompous old physician who condescendingly said to him, "You produce tragedies, don't you, young man?" "I do," replied Dumas, "like you, only your tragedies are bound in oak."

A LAY READER.—The powder so largely advertised in the newspapers is only an imitation of the original Carlebad Saits. The case you refer to as recently in the American Law Courts arose from the fact that poison was sent to a man of the name of Barnett in a Kutmow powder bottle. This man died, and the tragedy is reported in a New York exchange to have ruined the Kutmow powder butiles in the United States. We know nothing of the other nostrum about which you ask for information.

in the United States, we know housing of the County which you ask for information.

DR. GEORGE FLEHING'S paper on "The Eradication of Tuberculosis" is marked for early insertion.

OUR PARIS CORPESPONDENT.—The clinical lecture by Professor Potain on "Fever during the Convalescence of Typhoid" received

Meetings of the Societies and Lectures.

WEDNESDAY, MAY 17TH.

THE TREATMENT OF

GONORRHEAL SALPINGITIS. (a)

By J. W. TAYLOR, F.R.C.S.,

Surgeon to the Birmingham and Midlands Hospital for Women, Consulting Surgeon to the Wolverhampton Hospital for Women.

GONORRHEAL salpingitis is now a well-recognised disease, but many of us can remember the time when the connection between "inflammatory disease of the uterine appendages and gonorrhea was by no means established.

When Noegerrath published his treatise in 1872. maintaining that gonorrhea had dreadful consequences; that it was the main cause of pelvic periquences; that it was the main cause of pelvic peritonitis and sterility, and that it was practically an incurable disease, men first of all looked upon him as a wild dreamer and enthusiast. Then, little by little, abundant evidence was found to corroborate most of his assertions, but it was only very slowly that his work received any recognition or support. It was not until some ten or fifteen years later that the seriousness of general or fifteen years later that the seriousness of gonorrhea in the female began to be generally recognised, and enterprising surgeons began to operate freely for inflammatory tubal disease by removal of the uterine appendages.

At first operation was generally limited to the removal of the appendages on the side chiefly or solely affected at the time when the operation was undertaken, but the after-history of these cases was not altogether satisfactory. In many instances extension of the disease occurred on the opposite side, and in a short time the patient was in quite as bad a condition as before operation, so that a second section was needed for the removal of the remaining

appendages.
In consequence of this, attention was directed to the advisability of complete removal of the appendages in all cases of operation for "inflammatory disease." Papers were written on the subject-notably one by Mr. Tait—advocating this treatment, and for a considerable time it was accepted as final that thorough removal of the uterine appendages by abdominal section was the one and only cure for gonorrheal

salpingitis.
But there were difficulties in the carrying out of this advice, and the results, while in some cases very this advice, and the results, while in some cases very successful, in others were decidedly disappointing. In separating the adhesions, which were often very dense, the bowel—particularly the sigmoid flexure and rectum—was liable to injury, and injury in inaccessible regions. Further, the ovary, when peeled or torn away from its surroundings, left some of its tissue behind it, and with this there was often persistent menstration: the uterus, which had exidently been the centre of infection throughout persistent menstruation: the uterus, which had evidently been the centre of infection throughout, remained untouched, and in a small proportion of cases, notwithstanding the utmost care, local peritonitis and fæcal fistulæ resulted, while in others, notwithstanding the utmost thoroughness, menor-

(a) Paper read before the British Gynecological Society, May 11th, 1899. For discussion see page 535.

rhagia and pain persisted after operation, the hæmorrhage in some of these cases being rather aggravated than otherwise by the means undertaken for the cure of the disease.

In the meantime, while this experience was forming or, at all events, before it had been fully formed, Pean and Segond in Paris, Doyen of Rheims, and Landau of Berlin, recognising the gonococcus as Landau of Berlin, recognising the gonococcus as the source of the disease, and gonorrheal endometritis as the starting-point of infection for both Fallopian tubes, not only argued with true logical deduction that the uterus should be removed, but proceeded directly to put this reasoning into practice. tice, and began treating cases of inflammatory tubal disease by extirpation of the uterus as well as removal of the tubes. This was done by the vaginal route, and the result was, on the whole, more satisfactory perhaps than any treatment previously adopted. At all events the treatment was a radical one, and if the patient made a satisfactory recovery, there was, of necessity, no further trouble from uterine hæmorrhage, or from the pain and distress accompanying the pelvic congestion recurring at each menstrual period.

This practice has never been thoroughly adopted and followed in England as a primary procedure, but many English surgeons (including myself) have been over and over again glad to avail ourselves of vaginal hysterectomy as a cure for rebellious cases, and it would be difficult to speak too highly of its value

when every other means has failed.

On looking back over all this period of strenuous surgical effort—whatever may have been its mistakes of enthusiasm and misdirected energy-we cannot withhold a hearty acknowledgment of the courage, the perseverance, and the honesty of purpose which marked in the main each point of progress, or a warm appreciation of the splendid saving of life which has attended one department of the work from the very beginning-viz., the operative treatment of pyo-salpinx.

It must, perhaps, be remembered on looking back over this period, that the issues involved in the work then beginning were by no means so simple and definite as represented in my imperfect sketch. Side by side with the question of the cause of pelvic inflammation and its treatment was the question of its seat—whether it was usually within the peritoneum ("perimetritis") or in the cellular tissue outside it ("parametritis")—and with the elucidation of this problem Birmingham was, perhaps, more this problem Birmingham was, perhaps, more directly concerned than with that which I am now more immediately discussing. In addition to these two problems a subsidiary one, but one more pressing, was the question of the danger of this "pelvic inflammation" if left alone, and there can be no doubt that some operators were so impressed with this danger, and so impressed it on their followers that for a considerable period the finding of any inflammatory tumour in the pelvis was considered a valid reason for immediate abdominal section.

All this has been vastly altered during more recent years. With greater knowledge and more certainty of diagnosis there is more careful differentiation of grades of inflammation and the necessities of individual cases; we know better what may be expected

from rest and medical treatment, and operation is reserved for the minority of cases—or, if this goes too far, it is certainly not practised anything like so frequently as in former years.

But what about these cases—cases of undoubted salpingitis—that are not operated upon? Do they, if they improve under rest and bygienic treatment, necessarily relapse and get worse again, as we formerly thought, or do they get permanently well?

These are questions which I felt needed answering,

These are questions which I felt needed answering, and as I could not find any answer that I could trust, I set myself to study the disease as well as I could, hoping to find the information I needed by experience.

If I am not in a position to speak as definitely as I should like this evening, I feel I have learnt during the past thirteen years a few facts about the history of the disease and its course under treatment that influence my own practice and justify me, I believe, in bringing the subject before the notice of my colleagues.

One of the first things that struck me in the clinical study of salpingitis was the frequency of a syphilitic history; indeed, in many cases it was more easy to elicit this than any clear history of a gonor-rhoad discharge, and for some time it was a question with me whether syphilis was not a factor in the causation that had been overlooked.

Gonorrhea—the gonococcus—was perhaps the only source of gonorrheal inflammation in the mucous membrane of the tube, but was it the sole cause of tubal obstruction, tubal distension, and pyo-salpinx?

In some cases of pyo-salpinx possessing a syphilitic history, I have found at the operation a clearly defined nodule of thickening at the uterine end of the tube—a nodule which on section had all the appearance of a syphilitic gumma. In all cases of marked pyo-salpinx the abdominal ostium of the tube is more or less occluded by tubal and peri-tubal swelling, and it is at all events possible that a syphilitic thickening of the tube may assist in the contraction of the abdominal ostium which appears to be the necessary and immediate cause of tubal distension from retained secretion.

On consideration, however, of other cases of acute pyo-salpinx in which there could be no syphilitic history, and in which the obstructive swelling at the uterine end of the tube was amply accounted for by the acuteness or severity of the inflammation surrounding it; on consideration, too, of what I may term the natural frequency of the two diseases in the same individual, I felt that the point—interesting as it might be—was of little practical value, and that in all probability the ratio of syphilitic and non-syphilitic cases was not appreciably different to the ratio of syphilis with gonorrhea, and gonorrhea alone, irrespective of tubal disease.

So far, if my work had not been misdirected, it was barren of any very profitable result. But, after a time, another point began to engage my attention,

which bids fair to be of greater value.

This point I may perhaps express as the greater tractability of gonorrheal salpingitis in syphilitic subjects, in other words, after some months or years of treatment I found a perfection of cure in my syphilitic cases that I failed to secure in cases of pure and uncomplicated gonorrheal origin.

Before we consider the reason of this, and as I do not want you take anything for granted, I will run over as shortly as possible a few of my cases which

are more prominently in my mind.

Mrs. C. is a patient I have known and watched for fifteen years. When first I saw her (in 1884) she was suffering from syphilis contracted from her husband, and had recently had a miscarriage (at four months) which I considered to be due to syphilitic disease.

On recovering from the miscarriage she almost immediately showed signs of gonorrheal infectiona dangerous time for infection to take place as the uterus is temporarily dilated. She had gonorrhœal vaginitis and the inflammation spread upwards. Pelvic inflammation followed, and a mass formed in the pouch of Douglas, having all the characters of an enlarged or distended tube. For nearly the whole of the next year (1885) she was rather seriously ill—a constant patient—and was kept on mercurial and iodide treatment. The tubal tumours did not materially alter, and I was thinking of removing it by operation, when in September of this year she unexpectedly became pregnant. The complication of a (possibly) syphilitic pregnancy, very liable to The complication abort, and gonorrheal salpingitis was specially awkward from a surgical point of view, and as the general condition of the patient had improved, I decided to wait, maintaining the anti-syphilitic treatment mainly for the sake of the coming infant. The patient went to her full time and was delivered on May 29th, 1886, of a boy, who remains alive and well to the present date. After pregnancy was over the tumour of the damaged appendage was still to be felt. Occasional, but no persistent treatment was maintained, and although the tumour steadily decreased in size and fixity, I find from my notes of occasional consultations after this date that it was not until 1890 that all traces of the tumour had disappeared. This disappearance has been final.

About eighteen months or two years ago the patient's husband died. She has rather recently married again—much more happily, I believe—and is now (at the present date, November 14th, 1898) about six months' pregnant, without a trace of discoverable disease on the most careful examination.

Mrs. D. I have known and occasionally attended for eighteen years. A short time after her marriage she was infected by her husband with syphilis, and left him. For some twelve years she maintained herself, every now and then having some transient syphilitic symptom or affection which received temporary treatment, but the treatment was left off as soon as the symptom was relieved. On the whole, she had fairly good health, and at no time did she have any

pelvic. menstrual, or vaginal trouble. In 1892 a reconciliation was effected with her husband, and she returned to him. Early in 1895 she began to suffer with pain in the right side, pain in the right leg and hip, worse on standing or walking, worse on changing position, not worse at night. At first nothing definite could be found. She went to the seaside for a change, and while there was seized with violent peritonitis, during which, I understand, her life was despaired of. She had the advantage of every comfort and advice, and a London opinion was obtained for her. After some weeks of careful nursing she returned to Warwickshire, thorough invalid, and I again saw her. I then found marked disease of the uterine appendages on the The inflammatory mass formed a right side. rather large tumour, and the parts were fixed, but there was no fluctuation, or evidence of any marked collection of pus. I thought an operation would be necessary, but the patient wished to avoid it, and I was ready to try the effect of further treatment. Knowing her old history, and how well she responded in former days to anti-syphilitic treatment, I gave her grain doses of hyd. c creta and five to eight and ten grain doses of iodide of potassium. This she has taken ever since, and with steady improvement — improvement without the slightest relapse. She has now no trace of disease on binary of the steady improvement. manual examination. She is in robust health, and

can walk ten or twelve miles with enjoyment.

Mrs. E. is a patient I have also known for about eighteen years, though I have only very rarely at-

Digitized by Google

tended her. During a large portion of this time she and her husband have been under the care of Dr. Bull, of Sparkhill. He has attended both of them

for gonorrhea and syphilis.

In July, 1895, I was asked to see Mrs. E. in consultation with Dr. Bull. She had been confined to her bed for some weeks. She had severe abdominal and pelvic pain, and her temperature had been varying between 100 deg. and 102 deg. F. I found well marked tubal disease—a mass on the right side reaching above the groin—but the exudation was hard and resistant, and there was no evidence of any large collection of fluid.

I advised mercury and iodide as in the previous case, arranging, however, to see her again if there was no improvement, so that operation might be undertaken if necessary. From this date the patient steadily improved. I saw her nearly a year afterwards, and there was no trace of the old disease. I wrote to Dr. Bull last week, asking for news of her. He states:—"Mrs. E. is in good health, and is now managing a business." This patient has had a child since her attack of salpingitis, but it was born at

seven months and only lived one day.

Mrs. F. was brought to my hospital out-patient room on Feb. 26th, 1896, by Dr. Vince. She was 20 years of age, and had been married nineteen months. She had one child, living, and of good general health. Pain had been complained of in the left side for six This was steadily increasing, was worse one week after menstruation, and prevented her from attending to her duties. The case was already recognised as one of gonorrheal salpingitis, and my opinion was asked regarding operation. I found a hard, tender mass to the left of the uterus, rather fixed, and agreed with the diagnosis already made. I had some talk with Dr. Vince regarding my experience of these cases, and asked him if there was any history of syphilis as well as of gonorrhea. On March 3rd I received the following note from him :- "Since seeing you I have found there is a distinct history of syphilis in the husband. He is under me now with brain trouble, probably gumma. He has a gonorrhœal discharge at the present time, and the baby is practically blind from gonorrheal ophthalmia.' thought it quite possible that the case might improve with specific treatment, and ordered the patient a mixture of the red iodide of mercury (gr. $\frac{1}{5}$) with iodide of potassium (5 grs.) to be taken three times a day (a formula which I use largely for continued administration). This she has now taken continuously for nearly three years, and with steady improvement—improvement in which there has been no history of relapse whatever. The recovery has been slow but sure and uninterrupted. More than a year after the treatment was begun I find this note:—"Appendages palpably diseased on both sides, but not tender."

To-day (November 10th, 1898) I have examined her and find that the right ovary is still fixed, but this is the only pathological condition to be found. The patient herself states that she is perfectly well, has no pain or discomfort, and wishes to know if she may discontinue her attendance.

I could, if I liked, supplement these cases by several others, but the four I have cited will, I think, suffice. Everyone must acknowledge that they are capital examples of cure after severe gonorrheal salpingitis. One patient can walk twelve miles with comfort, another manages a business which she has taken up since her illness, another who has only just regained her full health has, nevertheless, through the time of treatment, been attending to the cares of her family and the needs of her syphilitic husband, while another, after seven years of freedom from disease, has buried her miserable past, married again,

and is six months pregnant with the first child of a second family.

Can anyone show similar cases of recovery after conorrheal salpingitis in non-syphilitis cases? I confess that until quite recently I could not produce them or anything really approaching to them in my own practice. And if the general consensus of skilled professional opinion is to be trusted there has been no expectation of or belief in similar results since the publication of Prof. Sinclair's book in 1888.

If the cases I have brought forward then are at all exceptional in their recovery to what are we to attri-

bute the happy issue?

Is the poison of syphilis in my way antagonistic to that of gonorrhea? I do not think that this can be maintained for a moment. The one disease does not in any way prevent the other, and untreated cases of both diseases in the same individual are among the very worst that I have encountered. I am forced to the conclusion that the treatment of the case is the main factor in recovery, and I in recovery, and I am far more interested in putting as clearly and forcibly as I can this fact before the notice of the Society than in maintaining any special theory of its mode of action. At the same time, when I consider the difficulty in the untreated disease, not so much of obtaining temporary resolution of inflammatory products—this can often be obtained by simple rest in bed-but of obtaining a cessation of relapses and a steady progress towards permanent recovery, and when I find this recovery repeatedly following a prolonged and uninterrupted course of special treatment, I question whether this effect is attained simply by promoting absorption, but am more inclined to believe that the mercury collected in the tissues of the body after persistent administration has some direct antagonistic action to the vitality and spread of the gonococcus in the deeper layers of the mucous and in the submucous tissues. In contradistinction to the opinion expressed by most writers of the last decade I believe it may be possible to destroy the power of latent gonorrhea, as well as that of distinctly local and acute affection, and that this may be attained in a marked degree by the use of the very same means by which we attack the poison of syphilis.

Since coming to this conclusion I have treated several cases of pelvic gonorrhea uncomplicated with syphilis by mercury and iodides, and, in every case in which it has been possible to continue supervision and treatment, I have had very similar results to those already reported. It will be obvious, however, that in most of these cases the duration of treatment has been as yet insufficient to fully test the value or permanence of its results, and that without general acceptance of the principles on which the treatment rests there is, and will be no likelihood of obtaining the same hearty co-operation on the part of the patient and medical attendant that is so well and cheerfully given in syphilis. One case in point is that of Mrs. G. She came to my out-patient room on September 23rd, 1896, with the history of abdominal and pelvic pain of some months' standing. She was also suffering from a chronic vaginal discharge. On examination I found that both of the uterine appendages were inflamed and adherent—that on the right side was adherent to the uterus only—that on the left was adherent to the pelvic wall. On October 22nd I put her on the biniodide mixture to which I have already referred. She took it during October, November, December and January, and at this date was so much better that only faint traces of any disease remained in the pelvis, and she herself refused further attendance. For half a year I did not see her. She returned on July 8th, 1897, complaining as before. Treatment was resumed, and she has continued it until the present date. The uterus is perfectly free and movable, and there is no trace of disease to be found on examination.

Another case of different type—recent and acute (the notes of which are entirely furnished by the patient's medical attendant), may fitly close the series to which I ask your attention at this stage of

my paper.
"Mrs. H., act. 30, has three children. The last child was born on March 25th, 1898, and a good recovery was made from the confinement. After a short visit to some friends in the following July, Mrs. H. returned home on July 16th in the best of health. On July 19th she felt some vaginal irritation, followed by vaginal discharge, and on July 22nd (the doctor states) I was called in to see her. I found her in bed, suffering from great abdominal pain, more especially on the right side of the abdomen, and from a profuse purulent discharge from the vagina. The temperature was 101 deg. F., and in the evening this rose to 104 deg. F. On inquiry and examination of the husband, I found that he also had a discharge from the urethra, which, to my mind, was a typical gonorrheal discharge. As important questions were involved in the diagnosis, specimens of the discharge were sent to London for bacteriological examination, and gonococci were found in abundance.

"The pain, temperature, and discharge continued in spite of douching and other remedies. On August 9th, Dr. Annie Clarke saw her in consultation, and found the uterus fixed and the right half of the pelvis completely

roofed by hard inflammatory swelling.

"On August 21st acute pain was complained of on the

left side of the abdomen.

"On August 31st, it seeming probable that some operative interference might be needed, Mr. Taylor, of Birmingham, was called in. Gonorrheal salpingitis, with its attendant sub-peritoneal exudation, was found on both sides, but at only one point was there any indication of possible 'pus' formation.

"Specific treatment was advised in the form of a biniodide mixture, and suppositories of ichthyol were ordered for vaginal use.

"From ten days to a fortnight after this date there has been steady and continued improvement. The patient got up for the first time on September 25th."

In a letter dated November 14th, 1898, the doctor

"I am glad to tell you that at last our patient is out again, free from all pain and discharge, but naturally very weak after her long and trying illness. I made a reginal examination last week and all that was to be felt was a hard, cord-like band running across the roof of the vagina on the left side. The right side was apparently quite normal."

[To be concluded in our next.]

CASE OF DOUBLE PYO-SALPINX,

IN WHICH

ONE OF THE TUBES CONTAINED NINETEEN OUNCES OF PUS.—REMOVAL

BY ABDOMINAL SECTION.—

RECOVERY. (a)

By JOHN CAMPBELL, M.A., M.D., F.R.C.S.Eng.; Surgeon to the Samaritan Hospital for Women, Belfast, and Assistant Surgeon to the Belfast Maternity Hospital.

THERE are on record several instances of the Fallopian tubes having become distended to enormous dimensions—e.g., Lawson Tait removed seven litres of fluid from a hæmato-salpinx; Stemann operated upon a tuberculous tube containing two litres of pus; and Championnièrre met with a pyo-salpinx in which

(a) Paper read before the British Gynecological Society, May 11th, 1899. For discussion see page 535.

there were about twelve hundred grammes of pus. The case, however, to which I now venture to call attention presents several features of interest independent of the size of the tubes. The fact that the tumour attained such proportions without causing any notable amount of pain is in itself remarkable. Further, the almost entire absence of adhesions is quite contrary to all my experience of pyosalpins, as I have invariably found the larger collections of pus associated with numerous dense adhesions, Finally, the origin of the condition is somewhat obscure. No history of urethritis or vaginitis could be obtained. The patient had only been married for ten months, and had never been pregnant. There was no rise of temperature or other sign of tuberculous disease. From the thickness of the walls of the tube, and from the absence of acute symptoms; I am inclined to believe that the pus must have been present long before marriage, and that it must have originated in connection with some illness during childhood or adolescence. The following is a brief history of the case:—Mrs. C., et. about 27, and married ten months, consulted me on April 25th, 1898, about an occasional pain in her left iliac region. She had never been pregnant. Menstruation was regular every four weeks, lasting four days, and only sometimes accompanied by pain. Micturition was normal, and had always been so. The bowels were confined. She was a robust, well-nourished, somewhat plethoric woman. Both breasts contained secretion. The abdomen was distended by a firm oval tumour, springing from the pelvis and extending to within two fingers breadths of the navel. It was most prominent to the left of the middle line. On vaginal examination the uterus was found to be retroverted, with a large movable tumour above it, and a smaller fixed one below and to the right of it. The urine was normal. Operation was advised and was performed on May 3rd, 1898. A median incision exposed the larger tumour, which proved to be the greatly distended left tube. Nineteen ounces of pus were withdrawn by aspiration and the tube was removed. The right tube was then found to be in the pelvis and slightly adherent. It was removed entire. From its appearance I estimated that it contained 3½ or 4 ounces of pus. Both ovaries were much enlarged, and firm and tough in consistence. They were resected, the portions left being about the size of normal ovaries. The patient made an excellent recovery. I examined her on March 15th, 1899, i.e., about ten months after operation, and found the uterus slightly retroverted. She enjoys good health and has been menstruating regularly.

I am indebted to Dr. Lorrain Smith for having preserved the specimens for me.

INSANITY AND EDUCATION.

By W. R. MACDERMOTT, M.B. T.C.D., Medical Officer of Poyntzpass District.

A common question put to medical men nowadays is: Why insanity is increasing? When we admit the increase, what is the usual answer? We either say that it is due to unwholesome conditions of life, abuse of alcohol, tobacco, tea, and so on; or the contrary, to better and more secure conditions of life whereby through arrest of natural selection, panmixia, the insane, and those predisposed to insanity survive to taint more deeply the race. The last answer looks the deepest and most learned.

Without any very clear insight into the nature of a disease we can often give grounds for it on the base of concurrence of facts. In modern life diffusion of education concurs more nearly with increase

of insanity than any other fact, both being terms of mental import. But if relation of cause and effect exists it has not only to be established but valued. If ten millions of children are being educated—that is, exposed to mental strain with the result that a greater proportion of them become insane than would otherwise be the case—it does not follow that mental exercise is wrong or undesirable, since the benefit to the many may far outweigh the injury to the few. They could not be trained to ride horses or cycles without increase in the chapter of accidents, but no one would say that therefore they should not become horsemen and cyclists. If, however, education does conduce to insanity, it may be not in principle but in practice, in faults of educational method.

Our definitions of insanity and education, we should realise, are highly conventional. The philosopher Dalton, of atomic theory fame, is said to have scandalised a meeting of Friends to which staid body he belonged, by appearing in a pair of bright red stockings. They seemed to him to be sober grey, but we would not doubt his sanity. If, however, he laboured under the sense impression that his leg was brittle or made of glass, or if he was affected as the man Tuke tells us of, who lost the sense of self-identity and looked for himself under his bed, or if he had suffered from any one of the large class of similar abnormal impressions he would not have escaped so easily. If, however, it is allowed in his case that there was no defect in judgment, no mental disease, it is not easy to see how such disease comes to be affirmed in what are at bottom precisely similar cases. The same thing applies to disease of expression; the line we draw between somatic and mental state in aphasia, and the allied affections seems a very arbitrary one. In general we allow abnormal sense impression and expression to be consistent with normal mental state so far that little room is left for

mental disease in any true sense. Our ideas of education are, I am afraid, not only equally conventional, but false and vicious. When we analyse our mental existence we find its most striking characteristic impersonal operation. All our higher mental determinations might as well be obtained by an impersonal mind dead to us as by our personal selves. Psychologists who insist that the phenomenal object has no existence independent of the percipient mind convict the whole human race of insanity, but in doing so they unintentionally define insanity, and what is so near it, crime. In popular thought, an orange, to use the classical Berkleyan simile, has independent existence, and is the cause of our sensation and perception of it. But-and I am not to be understood as trifling—insanity is disease of the common way of thinking, even if that way is psychologically erroneous and, what is strange, the disease takes on examination far more nearly than could be supposed the form of mind which is true and normal according to the psychologist. If a boy runs away with the orange from an apple-woman's stall he will scarcely defend himself by saying that it was a product of perceptual synthesis in his own mind, but we would certainly decide that he was far too much under the influence of the personal egoistic mind, and that it would be advisable to teach him, if necessary, by the birch, to reason in the usual impersonal way, however erroneous psychologically it might be. In general, the marked characteristic in the insane and mentally degraded is personal egoistic thought, inability to truly distinguish phenomenal object with consequent delusion by taking it as a product of mental synthesis, the process just as it is most strongly marked betraying its own radical incapacity. Again there is inability to eliminate personal self in the usual way from such ideas as God, king, beggar-man, and so on, and from ideas of relation so that the insane person imagines

those in contact with him to be absorbed in thought about him, conspiring against him. Further the imperious control which the ordinary realisation of independent objective existence exerts on him being weakened, he is left more completely to the unregulated impulses of the personal mind. But this exactly answers to the concrete, self-contained individual mind of psychological definition entirely dependent

qua mind on personal nature.

In our educational system, or rather negation of system, it is practically thought enough to bring the personal mind of each subject into conformity with a resultant obtained by a reaction of such minds on each other now and in past time. It is enough, that is, to bring the subject into conformity with some more or less generally received and established canon of thinking and of conduct as flowing from such sensus communis. But when we examine the social mind we can easily see that it is not only largely formed on the concrete personal mind, but superadds to it grievous faults of its own. The child is consciously and unconsciously trained up to conform thought and conduct to a conventional standard of sanity, the vices of which it takes no Jeremiah or Juvenal to detect and denounce. Insanity at bottom is an exaggeration of the personal egoistic mind, is aberration in some ways from the impersonal mode in thought, but if we examine morbid ideation in the actual field we will find that it affects nearly entirely what is acquired by or socially impressed on the mind. It may be said that such is the case, simply because man learns to think just as he learns to walk, ride or play the piano, that his mental are as much acquired as his bodily abilities, and that, therefore, mental disease would necessarily show itself in reference to acquired ideas. Suppose, however, a man learns to swim, he is determined by physical constants in the nature of his own body and of water. In the same way, when he learns to think, he is determined by a physical nature in mind absolutely independent of him, by what are called the necessary laws of thought. But if one thing is more certain than another it is that as the personal egoistic mind intervenes he cannot even learn to swim aright, he is timid, awkward, miscalculates his powers. Much more since such mind does not give the necessary laws of impersonal thought he is unable, just as he is under its influence, to think aright if at all.

But the personal mind, a bundle of sensations, perceptions, and emotions, can be trained, educated up to a certain conventional standard of formal thought. Animals which have no other mind can be trained to do wonderful things, and no doubt they have formal automatic thought in doing them. I have often noticed, however, that performing animals have a puzzled, downcast, hang-dog look, as if beartily ashamed of themselves, and doubtful of their own sanity. The Anti-Vivisectionists should look after the moral dignity as well as corporeal integrity

of their proteges.

We hardly realise how much for mankind education and social training are based on the personal, that is the really insane mind. I said just now that the boy who stole the orange should be taught to think impersonally by the birch, if necessary. By a system of rewards and punishments directly influencing the personal mind and conformed to its nature, the boy no doubt can be got to let the orange alone, but he is not thereby made to think impersonally that is sanely; the very contrary is the result; he is conformed more implicitly to the nature of personal mind.

It cannot be said that education is worse now, more directed to influence the purely personal mind than "when civil dudgeon first grew high and men fell out, they knew not why," when the belief in witchcraft and other forms of social insanity prevailed. The contrary is, perhaps, the case; the impersonal mind has a larger field of exercise with the advance in physical and natural science. What, however, has undoubtedly happened is that a vastly increased number of persons are now brought under educational influences directed to develop the personal mind on its own lines, that they are trained exactly as performing animals are.

as performing animals are.

The common plea for education is itself an illustration of this. The plea is that it opens a career to the subject, that it promises better social position, improved material status, what-not. This incitement directed to the personal mind is a false one, the promise is not and cannot be kept; the number that from this point of view education deceives and disappoints is far and away greater than the number it

serves.

Far and away the greater number of children who attend our schools settle down as labourers, small farmers, and so on, with little or no opportunity or occasion for the three R's. It would not be true, however, to say that they are in the same mental state as if not educated. There is a discontent and impatience with their lot which the totally uneducated seldom show, there is too much of the "a man is a man for a' that" in them, a touchy sensitive personality with a rare crop of curious bizarre notions, the product of the perceptual synthesis of the psychologists, utterly at variance with the laws of impersonal mind. They are, as I conceive, far more predisposed to insanity than the uneducated. I suspect that the ratio of insane per 1,000 of illiterates would be found much lower than the ratio per 1,000 of those subjected to an ordinary school education, but I have not ascertained the point, writing currente calamo.

But it will be said that education must be conformed to the personal egoistic mind, to its desires, vanities, ambitions, tendencies. If so, we must pay the penalty. I, however, deny the position on grounds which the limits of this article do not allow me to

give.

It is enough to say that the position of the psychologist and evolutionist is a very questionable one. It is open to question whether there is any "human mind," as a distinct entity evolved from or in relation with the nervous system. It is more consistent with the mass of biological facts to take mind as an independent natural form of existence in varying conformity to which animals are evolved in much the same way as to physical conditions, the bird to air, the fish to water. On this supposition the impersonal form of mind which man touches, but rests only insecurely on becomes quite intelligible. But as man rises to, rests on the impersonal level it is disease, insanity, in him to revert to the personal level.

It would be ill for us if our faulty system of education was not antagonised and corrected by our unconscious race education ever tending to develope the impersonal mind, the natural effect of having in so many directions to reason impersonally. other words, as far as education opens up to us modes and subject matters of impersonal thought it serves to counteract the evil of training us like animals, who, in a certain sense, are made insane by an education non-natural to them. Still, while for human beings the impassive operation of impersonal mind is natural, it is only imperfectly so, and while education does incidentally cultivate the operation, and therefore tends to raise us to the higher level, it is at the expense of an unconscious and almost unintelligible struggle with the personal mind, animated by egoistic motive. Education rejecting the motives of the personal mind is almost unintelligible and yet impersonal, that is sane thought, allows no more place for personal motive in conduct than in geometry; if the law of mind is

independent of the personal agent in one case it is so in the other. This may seem a hard saying, but it really follows once we allow that mind is an independent natural existence to which we are conformed in higher degree than the lower animals, but still only in varying degree.

Thirty years ago Maudsley, in his "Physiology and Pathology of the Mind," taught that pyschic laws are the same in healthy and diseased phenomena, only they do not operate under the same conditions, and therefore produce different symptoms. We have travelled so far from that, as I conceive, sound position, that a case of colour-blindness, or, for that matter, every abnormal bodily state should logically be regarded as insanity. We are taught now that psychosis and neurosis are inseparable concomitants, that disease of the last implies disease of the first. Without entering into a discussion of the position it is enough to say that the most effective limitation of insanity we hafe is the essentially impersonal habit of distrusting and questioning our sense impressions and emotional impulses, and education ought to be directed more than it is to develope that habit.

I will end with a more practical suggestion. I see that in Prussia, among the most highly educated people in Europe, the number of the insane in asylums rose from 13,267 in 1875 to 66,888 in 1897. That is only one illustration of many I could give of the wisdom of hesitation in enforcing the policy of compulsory education to the bitter end. It might be as well to go slower. Parliament voted between eight and nine millions the other day for education in England and Wales. It would be better if it voted more millions to raise the material status of the people; it looks like social insanity to aggrauate the lot of a mass of paupers or semi-paupers by an education certainly useless, and very probably with a tendency to add the

curse of lunacy to their misery.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.
MEETING HELD THURSDAY, MAY 11TR, 1899.

The President, Dr. H. Macnaughton-Jones, in the Chair.

LARGE INTEA-CYSTIC MAMMARY SARCOMA REMOVED BY OPERATION.

Dr. Herbert Snow exhibited a photograph of this specimen, excised in April last, The patient was a married woman, et. 56, two children. There was no history of injury, but there had been much recent trouble and anxiety, to which, with pressure by tight stays, the growth was attributable. It appeared only one and a-half years previously, and had rapidly grown to a huge size, forming a prominent borsy mass of unequal consistence. Was first noticed as a little lump under the inferior aspect of the organ. There was a dull continuous aching pain, but the general health was sound. The axillary region was tender, but there was no gland enlargement. The skin was enormously distended, livid, marbled by large veins; the nipple almost obliterated by the pressure; the whole mobile.

On excision the growth proved a congeries of whitish fibrous masses, which had developed without a primary cyst. Part of the cyst-wall remained, but most of the fluid contents had disappeared (as usually happens in these cases) through continuous pressure. The solid remainder, after incision, weighed 4 lbs. 4 ozs. The

wound healed by first intention.

The microscopic section showed transition between well-organised fibrous tissue, and the embryonic spindle-cells of true sarcoma. Formerly, these tumours were often allowed to ulcerate, and were termed "fungating adenoma." They proved then rapidly fatal, through exhausting drain of blood serum and attacks of hæmor-

rhage. Modern surgery rarely allowed them to proceed There were no metastases, and the localisation of the disease, with consequent curability by excision in even the most advanced stages, showed a striking contrast to the clinical phenomena of mammary carcinoma.

Dr. Hrywood Smith asked how the flaps were

fashioned in this case?

Dr. C. H. F. ROUTH remarked that he read a paper at the International Congress to show how often diseases of the breast were associated with and kept up by diseases of the uterus. As an example, he had a case in which he removed a breast for carcinoma; it healed up, but the wound kept on breaking down. He then examined the uterus and found a very large ulcer involving the cervix and vagina. He cured this, and the breast got quite well. He would ask Dr. Snow whether the condition of the uterus was examined in his case.

The PRESIDENT said that in some of these cases it was very difficult to determine whether the disease was a true carcinoma, or a transition between that and adenoma. He had seen some cases in which the clinical condition pointed to scirrhus, but a microscopic examina-tion showed it to be otherwise. Sometimes also both pathological and microscopical indications were so mixed up that it was very difficult to say what the condition was. Cases such as Dr. Snow's were not often seen at the present day, because they were usually operated on earlier.

In reply, Dr. Snow stated that although the skin covering was so tense, there was no infiltration of the subcutaneous tissue, as would have been the case with a carcinoma. He had dissected off sufficient flaps for union by first intention, and did not think there would be any recurrence. He fully agreed with Dr. Routh that uterine lesions might exert a considerable effect in causing mammary lesions; but believed that both much more often followed a common cause, the pressure of stays hindering development on the one hand, or healthy involution on the other. There were no uterine symptoms in the present case, and the woman was long past her climacteric. It was certainly, however, an excellent rule, in the absence of obvious cause for a mammary tumour, to seek it in the uterus. The errors in microscopic diagnosis, referred to by the President, Dr. Snow considered mainly due to reliance by pathologists on the phenomena of prepared sections alone. In these the true shape of the cells was often disguised or altered. It was most essential to examine the individual cells as nearly as possible in their natural state, as well as the hardened thin section.

1. Mr. J. W. Taylor, Birmingham, read a paper on "The Treatment of Gonorrhosal Salpingitis."

2. Dr. JOHN CAMPBELL, Belfast, read a paper on "A Case of Pyo-salpinx, in which one of the tubes contained 19 ozs, of pus."

These papers will be found in another part of the journal, under the heading of "Original Communications."

In the discussion on these two papers,

Mr. ALEXANDER FOULERTON said that there was a good deal of bacteriological evidence at our disposal with regard to the relative frequency of gonorrhoeal infection in the causation of salpingitis. He had carefully examined the pus from sixteen cases of pyo-salpinx with the following results:-Cultures of micrococcus gonorrhæa, staphylococcus pyogenes albus, and bacillus coli communis were each obtained in two cases, and of streptococcus pyogenes in one, and in all seven cases the parasite present was found in pure culture. In the remaining nine cases no culture appeared on the media, but in two of them the presence of bacillus tuberculoris was proved by other methods. The cultivation experiments in all sixteen cases included the inoculation of a smear of fresh human blood on an agar plate, with the view of obtaining cultures of the gonococcus if present. Such a series as this was, however, much too limited to permit of any conclusions being drawn from it. Accordingly he had brought together a number of results published by others; and in compiling the statistics he had taken into consideration only work published since 1890, and work done by those—such as Menge, Steinschneider, and others-who had devoted special attention to this

matter. Thus his own series of sixteen cases was the smallest individual series included. The following figures were, therefore, as free as possible from various sources of fallacy. In all he had been able to collect 499 cases of salpingitis so examined, and among these cases were 85 in which the gonococcus had been identified, or about 19 per cent. On going into the matter in detail, however, he found that in about 60 per cent. of the cases no micro-organism of any sort had been identified in the contents of the tubes. Out of every hundred cases of salpingitis, therefore, there were about sixty cases in which the pus was, at the time of examination, sterile; there were about twenty cases in which the gonococcus was present; and there were about twenty cases in which bacteria other than the gonococcus were found. And first as to the sixty cases in which the contents of the tube were sterile of bacteria, the explanation of their occurrence in so large proportion was probably a simple one. These cases did not, as a rule, come under bacteriological examination until the inflammatory process was already of some considerable duration; and the causative parasites had meanwhile died out, partly starved for want of nourishment, partly poisoned by their own excretory products—just in the same way that a number of animals would perish after a time if closely confined in a limited space. Then as to the twenty cases in which bacteria other than the gonococcus were present, a considerable number of these cases would have to be rejected when considering evidence as to the etiology of salpingitis, for the reason that the bacteria present were obviously there as the result of a secondary infection of tubes already in a state of inflammation from some other cause. Thus, whenever bacillus coli communis was found in a pyo-salpinx, Mr. Foulerton felt sure, as the result of a number of observations which he had made in various cases of pelvic suppuration, that its presence might always be attributed to a secondary infection from the bowel following the formation of adhesions between a tube already inflamed and some neighbouring portion of intestine. When, therefore, we considered only those cases in which the cause could be proved by the exact methods demanded in pathological research we found that the gonococcus was present as the causative parasite in considerably more than half such. And that this estimate is, owing to the conditions under which examinations are made, considerably less than is actually the case is highly probable when we take into consideration the further light thrown on the subject by clinical observation. He did not think, on the other hand, that there was much trustworthy of any sort that syphilitic infection important factor in the causation of evidence of was an salpingitis. As to the treatment of salpingitis he had very little to say, but Mr. Taylor had offered them a sufficient variety to choose from, ranging in severity from the administration of biniodide of mercury to the performance of hysterectomy. His own view was that since an inflamed tube was a serious source of potential danger to a woman, and a constant cause of ill-health, the sooner it was removed the better. But hysterectomy would, he thought, very seldom be necessary. With regard to the prevention of salpingitis, perhaps an even more important matter than its treatment, there was rather more to be said. Recognising as he did the frequency of gonorrheal infection as a cause of salpingitis, he thought that surgeons generally had not availed themselves of the assistance in the treatment of this disease which had been placed at their disposal as the result of pathological research. Thus a case of primary gonorrhoeal infection in a woman was almost invariably treated as a vaginitis by means of vaginal medication of one sort or another. Whereas it seemed to have been clearly proved that a true gonorrhœal vaginitis was a rather uncommon occurrence. Bacteriologists had shown that gonorrhoeal infection of the genital tract in a woman was first manifested either by a urethro-vulvitis or an endocervicitis, in the majority of cases perhaps by both. The vaginitis which occurred with gonorrheal infection was, on the other hand, not usually caused directly by the specific coccus at all, but was rather the result of the spreading upwards of an inflammatory process caused by

other bacteria which had gained access to the original lesion situated somewhere in the region of the external urethral meatus and caused by the gonococcus. Thus in 489 cases in which the vulval discharge was examined, the gonococcus was found 323 times, or in about 66 per cent. whilst in 680 cases in which the purely vaginal discharge was examined, the gonococcus was found only 54 times, or in about 8 per cent. Bearing these facts in mind the usual treatment of primary gonorrheal infection in women must be con-demned as inadequate. The treatment of the disease as a vaginitis was the treatment of what was merely a secondary complication; it might, indeed, incidentally have some good effect on the primary urethro-vulvitis, but left the primary endocervicitis untouched. And he thought that if more attention were paid to the condition of the cervical canal in cases of gonorrheal infection, the frequency of so serious a complication (as salpingitis undoubtedly was) would be very much diminished.

Dr. WM. TRAVERS congratulated Mr. Taylor on his paper, which dealt largely with the medical aspect of these cases. When he first took up gynæcology it was chiefly in its medical aspect; the advance of the subject had necessarily led him and others to treat it from the surgical standpoint; but there was still much to be said on the medical side. His own experience had been that perchloride of mercury cured many of these cases of gonorrhœa; and in his hospital practice he often gave the drug before resorting to operation. And as he went on, he found more and more cases cleared up by medical treatment.

Mr. C. RYALL thought that Mr. Taylor laid undue stress on syphilis as a cause of the symptoms of gonor-rhoa. At the Lock Hospital he found many cases of syphilis complicated by unrecognised gonorrhœa which had been overlooked. As regards preventive treatment, he did not think that enough credit was given to work done in this country. The best treatment of gonorrhea was, he thought, the local application of nitrate of silver, 40 grs. to the ounce, whether the infection was

one of the vagina or of the cervical canal.

Dr. C. H. F. Routh said the question was, What did really constitute gonorrhose? Were other bacilli that might be present hostile or otherwise to the gonococcus? They had probably no right to conclude that most of these cases were syphilitic, even if they had got well under antisyphilitic treatment; and they should always remember that every case of gonorrhoea should be treated

not only locally, but also on general principles.

Dr. R. H. Hodgson thought it made very little difference whether pyo-salpinx was due to gonorrhea or to syphilis. Mercury acted on both, and it was a drug that was specially well borne by women. It could be used with advantage also when the cervix was first affected, and in this way they could treat the disease itself, and

not merely its tubal complication.

Dr. George Elder (Nottingham) commented on the fashions that prevailed in medicine and surgery. A few years ago they were in the habit of removing the appendages when there was a history of gonorrhea with recurrent attacks of pelvi-peritonitis; but now, with the swing of the pendulum, they were becoming more con-servative in their methods. The mercurial treatment was advised twenty-five years ago, and the patients got well and remained so; but they were much indebted to Mr. Taylor because he had given them the reasons for the success of the treatment. With regard to Dr. Campbell's case, he had also seen patients with large pus-tubes who were able to get about, showing neither temperature nor much pain. The largest cases he had seen had been cases of mixed infection, where there had been communication between tubes and bowel.

Dr. ARTHUR GILES considered that Mr. Taylor's paper was one of great value, and that it would be increasingly appreciated when it could be read over at leisure in the journals. One point clearly brought out was that gonorrhea was in many cases complicated by an unrecognised syphilis, and that these cases consequently improved considerably under anti-syphilitic treatment. He was greatly interested in Mr. Taylor's remarks on the value of mercury in the treatment of gonorrheal

pyo-salpinx, even when syphilis could be excluded. This was a most suggestive point, and one which would probably be found very useful in practice. This teaching, which on the showing of some previous speakers, was not new, had probably lapsed; certainly he had not heard it in his student days. But independently he had experienced the value of mercury in the treatment of condylomata of the vulva, in cases where there was no suspicion of syphilis. He had often found that by the internal administration of the biniodide of mercury, combined with local applications of blackwash and blue ointment, condylomata nearly disappeared in a week. The infrequency of gonorrheal vaginitis was to be explained by the ana-tomical structure of the vaginal epithelium, which was stratified. Bumon had found that gonococci apparently had great difficulty in penetrating this epithelium, while they could attack the single columnar layer in the urethra and cervix with ease. He had long felt that the treatment of gonorrhea by applications to the vagina alone was very inadequate; and that the proper treatment in the quite early stages was to thoroughly disinfect the vagina and cervix under an anæsthetic.

The PRESIDENT said that Mr. Taylor's paper was an important one which would be sure to attract attention not only in this country, but also abroad. The discussion would help to remind them that gonorrheea and ayphilis were mixed up in a large proportion of cases; he had himself learned this from the careful observations of the late Tilbury Fox. In many cases where syphilis was denied without deceptive intention, there had really been some syphilitic infection. He had not so far seen the view advanced that mercury should be given in cases of advanced tubal disease; but this was a question that required careful attention. An important point in the paper was the conservative one of the advocacy of posterior vaginal section in the treatment of pyo-salpins. There were cases in which, as Mr. Taylor said, medicines were useless; and which nevertheless stopped short of pyo-salpinx. Still, the indication was operation. It would seem to him a dangerous thing to rely too much on the vis medicatrix nature, instead of treatment by removal of the adnexa. At the same time his firm personal belief was that many adnexa were removed unnecessarily. The points raised by Mr. Foulerton were of great importance; he had seen it stated that the gonococcus was found as the causal factor in 33 per cent. of cases of pyo-salpinx. It was also important that they should remember that the cervix was so often infected; much harm might be done by treating the vagina alone by forcible douching. He believed that the cause of the infrequency of vaginal gonorrhea was, as stated by Dr. Giles, the structure of the vaginal epithelium.

Dr. Campbell's case was a very interesting one, the absence of pain was a notable point in many of these cases. A year ago he showed a specimen at the Obstetrical Society, from a patient with a similar history; there was no pain until the function of the bladder became interfered with. It was a general rule that in tubal disease the symptoms might be very slight in propor-

tion to the severity of the condition.

Mr. TAYLOR, in reply, said that the main point in his paper was not the recognition of the fact of the complication of gonorrhea by syphilis; but that in cases of mixed infection improvement of the salpingitis could be effected by anti-syphilitic treatment; and that improvement might also occur in cases where there was no syphilitic history. He thought that both clinical and bacteriological examination would go to show that most cases of pyo-salpinx were due to gonorrhea or tuberculosis. The statement that primary gonorrheal vaginitis never occurred seemed to him too strong a statement; but it might be very transitory. It had long been recognised that the source of danger to the woman was the disease in the cervix; but he had found that mechanical treatment of the cervix and uterus might be disastrous, and might lead to salpingitis. In his opinion the treatment by suppositories was better. He had not found any harmful result from the vaginal douche.

Dr. CAMPBELL expressed his thanks for the interest

the Society had shown in his paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING HELD FRIDAY, APRIL 14TH, 1899.

The President, Dr. John W. Moore, in the Chair.

NOTES ON A CASE OF ADDISON'S DISEASE.

Dr. J. B. Coleman made a communication on the subject of diseases of the suprarenal capsules, and exhibited the viscera and microscopic sections of two cases, of which he narrated the clinical history. One case presented the classical symptoms of Addison's disease, and it occurred in a girl, et. 26, the duration of the disease being three years. Both suprarenal capsules were more than double the normal size, and were a mass of fibro-caseous material, containing giant cells and tubercles; sections of the skin showed brownish-yellow pigment in the cells of the rete mucosum; the heart weighed only five ounces; in the duodenum close to the pylorus there were pin-head-sized greyish nodules, due to hyperplasia of lymphoid tissue around the gland tubules. The other case was one of primary sarcoma of the suprarenal bodies, the patient being a man, æt. 23, who presented none of the symptoms of Addison's disease. For three months before his death he suffered from epileptiform fits and from weakness of his limbs; on admission to hospital he presented the signs of ataxic paraplegia; after a debauch he rapidly passed from a drowsy condition into collapse and coma; the necropsy showed both adrenals uniformly enlarged to the size of a man's fist, the growths consisting of round-celled sarcoma; there was a secondary growth about the size of a cherry in the wall of the right auricle; no tumours in the brain or cord; the cord showed degeneration in the motor tracts and in the posterior columns. Dr. Coleman suggested that the epileptiform fits and the degeneration in the spinal cord were the result of a toxemia, the latter being due to the diseased condition of the adrenals; under the depressing influences of the debauch the terminal symptoms were set up-drowsiness, collapse, and coma.

Dr. R. TRAVERS SMITH spoke.

Dr. Finny pointed out that great destruction of the suprarenals could take place without any of the symptoms of Addison's disease supervening. There was also ptoms of Addison's disease supervening. There was also a group of cases which presented all the evidence of suprarenal melasma, while a necropsy showed that the suprarenals were perfectly healthy. He himself had an example of the latter group under care. The patient was suffering from tuberculous disease, but the suprarenals were unaffected. He therefore thought it probable that the disease was due to some affection of the large nerve elements in the neighbourhood rather than to structural changes in the gland itself.

The PRESIDENT said that, as had been shown, there were three groups of cases—namely, disease of the supra-renals and pigmentation, disease without pigmentation,

and pigmentation without disease.

Dr. Coleman, in reply, said he thought Byrom Bramwell's theory the safest, in which he combined the suprarenal inadequacy and the nervous theory.

CASES OF PYLOBIC OBSTRUCTION.

Dr. Parsons read a paper on the above subject. The President, Surgeon Croly, Mr. G. J. Johnston, and Dr. Langford Symes discussed the paper.

CHRONIC PHARYNGITIS.

Dr. Robert Woods read a paper on chronic pharyngitis and its relation to nasal obstruction, in which he expressed his belief that mouth-breathing was the essential cause of chronic simple inflammations of the throat. He reviewed the chief functions of the nose, and pointed out how in mouth-breathers the disuse of the special apparatus for modifying the air, by warming, moistening, and filtering from dust, must affect the throat injuriously, since the throat was compelled to take palati be lifted, the pharynx wall under cover of it will be found normal. In addition to the more familiar forms of nasal obstruction, he drew attention to a common condition of the nose where the passage, though free enough in the daytime, became stopped at night. This results apparently from the difference in level of the head between the upright and horizontal positions, there being less drainage, and, therefore, greater tendency for the congested soft tissues to encroach on the air-space in the horizontal than in the upright. The paper concluded with a short account of the operative nasal treatment necessary for the cure of the condition.

The Section then adjourned.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD THURSDAY, APRIL 27th, 1899.

DR. MACFIE CAMPBELL, President, in the Chair.

Dr. John Hay related three cases of "Pulsus Para-I the first cases the abnormal pulse condition was associated with the dyspnœa of acute bronchitis in a child of three years, and was only a temporary phenomenon. The second case was one of pericarditis with effusion, complicated by serous effusion into the right pleural cavity. The removal of this fluid improved the pulse condition, but the pulsus paradoxus again became well marked, without a corresponding accumulation of fluid in the pleural cavity. The third case was one of reversed pulsus paradoxus, the arterial pulsation in the vessels of the right side of the neck and right arm disappearing during expiration. It was observed in a man suffering from aneurysmal dilatation of the arch of the aorta. The cases were illustrated by pulse tracings and charts of the chests.

Dr. Bradshaw considered that the anacrotic character of the pulse in the last case was due to the percussion wave being largely lost in its transmission through the sac of the aneurysm. It was followed by a slowly advancing tidal wave. The increased anacrotism during expiration was to be explained by increased interference with the passage of the tidal wave.

Mr. F. T. Paul exhibited a patient on whom he had

performed colotomy by a new method. The divided large intestine was conducted for some distance between the muscles of the abdominal wall and then brought to the surface. This allowed of efficient control by a light horseshoe truss.

Mr. THELWALL THOMAS spoke in favour of Frank's operation, and exhibited a photograph of a man operated upon six months previously, and who is now following his occupation. He saw objections to the Senn method.

Mr. Rushton Parker exhibited a boy whose right upper extremity had been almost totally avulsed by

machinery, necessitating the removal of the whole, except a short piece of the clavicle. The subclavian artery had been torn across. Injection of saline solution into the veins acted very beneficially.

Dr. Whitfford exhibited a patient who had suffered from lupus for seventeen years. She came of a very "tuberculous" family. Some of the scars as the result of treatment were elastic and almost undistinguishable from normal skin. The treatment had been scraping, with the application of caustic potash in sticks.

Dr. PERMEWAN read notes of a case of "Acute Rhinitis" which had caused general infection of the system, and in which treatment directed to the nasal condition caused

rapid subsidence of the fever, &c.

Mr. W. M. CLEMMEY related a case of "Rupture of Kidney," with secondary operation and recovery. The patient received a kick from a horse in the front of the abdomen on September 21st, 1898. The first symptoms of pain, collapse, and retching and hæmaturia were treated by fomentations and opium. On September 30th, owing to the temperature rising, the pain of a grinding character not eased, the loin was opened, exposing the throat in juriously, since the throat was compelled to take in flamed kidney, the rupture extending half way on the function of the nose. In support of this contention he quoted an observation he had repeatedly made, and into the pelvis of the kidney. Smart bleeding, that in these cases of chronic pharyngitis, if the velum controlled by ice and packing, followed. On December 6th, the tube was removed. On April 13th the wound healed, the patient since working as a timber carrier and being in excellent health. In three other cases of severe kidney injury with the ordinary symptoms of rupture no operation was required, rest, fomentations, ice, and opium being the treatment. Whether secondary lesions of the kidney will follow it is at present too short a time to say.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, May 20, 1899.

GUNSHOT WOUND IN THE CHEST.

M. Lucas presented a man of 35 at the Academie de Médecine who had received two months previously a revolver bullet in the chest. The orifice of penetration was situated a little to the right of the sternum towards the clavicle, and the projectile traversed the lung from above downwards. The man was brought to the hospital in an almost comatose condition; the pulse was small and irregular, and the patient spat up a large quantity of blood. The wound was washed with oxygen water and plugged with iodoform gauze, while the patient was recommended absolute immobility. The following day all the signs of a large effusion of blood in the right side of the thorax were present. Subdelirium accompanied by præcordial anxiety being remarked during the night, an injection of morphia was given, and in two or three days the effusion began to be absorbed, and finally the man recovered without any more trouble. The radiograph showed the ball to be lodged in front of the twelfth rib. The speaker said that he seized on this case to state in a few words the method to be followed in the treatment of penetrating wounds of the chest. Contrary to that which took place in penetrating wounds of the abdomen, for which the general tendency was to operate as early as possible, great reserve should prevail. Not only was it not necessary to interfere in the majority of cases, but the patient should be the least disturbed possible. He should be examined with extreme discretion, as the simple moving to practise auscultation might be fatal to him. patient should not be placed in the horizontal position, but rather half sitting up, so as to facilitate the laboured respiration. Against the hæmoptysis iced drinks hould be given, and purgatives, when the first danger had passed. To allay the pain and the agitation injections of morphine were good treatment, and if great weakness is observed recourse should be had to injections of serum.

The patient should be kept on liquid diet as long as possible.

PNEUMONIA AND CEREBRO-SPINAL MENINGITIS.

M. Rendu said that he had treated a child of 5 years who had been suddenly seized one night with severe rigor, followed by high fever and delirium. The following day she was in a comatose state, the pupils contracted, the pulse at 140, and the temperature at 106 degs. F. Nothing was observed at that time in any organ. The evening of the same day a bath at 92 degs. F. was given and an enema of eight grains of antipyrine, which produced abundant perspiration and a slight improvement of the symptoms. The treatment was kept up for four days and at the end of that time pneumonia of the apex of the right lung appeared. The cold

baths were continued and soon an improvement of all the symptoms was manifest, but a few days afterwards the child presented all the signs of cerebro-spinal meningitis (stiffness of the neck, contractions of the jaws and limbs, the sign of Kering, rise in the temperature, &c.) At the same time the pneumonia reappeared warm baths were substituted for the cold baths and four ounces of artificial serum were injected daily, small doses of calomel and bromide of potassium completed the treatment. A fortnight subsequently the child had fully recovered. The speaker concluded by saying that, although the direct examination of the cephalo-rhachidian liquid was wanting in this case, he believed that the microbe which provoked simultaneously the pneumonia and the meningitis was a pneumonococcus.

M. Netter said that he considered warm baths to be superior to cold baths in persons suffering from pneumonia complicated with meningitis. He obtained the cure of three patients by this treatment.

Germany.

FROM OUR OWN CORRESPONDENT.]

BERLIN, May 20th, 1899.

At the Surgical Society, Hr. Benda read a paper on Tuberculosis of Bones and Acute Miliary Tuberculosis.

He said that experience taught that general tuberculosis not infrequently followed operation for tuberculous disease of bones, and it was assumed that there was a direct connection between the operation and the succeeding disease, inasmuch as at the operation the veins of the bones had been opened and the tubercle bacilli had passed into the system through them. By Weigert's investigations and the proof of the penetration of the bacilli into the blood vessels, this assumption had fallen to the ground. Weigert had shown that penetration from a tuberculous centre took place into the great veins, or into the thoracic duct, and that no increase in the bacilli took place. From this arose a doubt as to whether disease of the bones afforded sufficient material for such a flooding of the system, and whether the small veins of the bones were large enough for the purpose. According to many authors, more remote penetration penetration from place, and had also taken diseased centres had been proved into a cerebral The speaker's own material consisted of sinus. cases in which general tuberculosis had three followed operations on bones. In all three cases penetration disease had been proved Two were cases of tuberculous coxitis, and one of caries of the vertebral column. In one case Weigert's tubercle of veins, and twice tuberculous endarteritis of the aorta and mitral valves were present. Here there was enormous growth of tubercle bacilli. But a conclusion here as to the relation of cause and effect between the operation and the subsequent miliary tuberculosis would be too hasty, as it was only an accidental one. From his searching investigation it was shown that the disease started in the intima of vessels. Here took place the first metastasis into the bones, and led to tuberculous disease into them, and also to the general tuberculosis. From this, therefore, there must be a limit to Weigert's conception as to relationships.

Hr. Felix Franke, Brunswick, related a case of Fibro-Plastic Ostitis.

A patient was admitted into hospital with chronic articular inflammation; on the outside of the joint were puffiness and fluctuation. On opening the joint a peculiar change was observed. The lower end of the femur was softened, and for a distance of 19 to 12 ctm. converted into porous tissue; only on one side was a small lamella of cortex. The bone could be cut with the knife-There was fibrous degeneration of the bone; thick fibrous cords passed through the tissue, and enclosed small sequestra of bone. There was very rapid softening of bone, as the first symptoms appeared in April and in July the disease had progressed so far that operation was necessary. The patient stated that eight months before the commencement of the disease he had injured himself by falling on the knee. The diagnosis arrived at was fibrous ostitis, without new formation of bone, with subscute course, and probably in connection with injury. The ostitis was clearly of a bacterial nature, possibly set up by the influenza organism; the patient had suffered for a long time from symptoms of that disease.

Hr. Riese related a case of

PYELITIS WITH CHRONIC APPENDICITIS
after an abcess on the right side with typhlitis. A large
swelling formed on the left side, which palpation showed
to be a renal tumour, then violent pain came on. After
some time swelling went down. After several
such attacks had taken place the speaker decided
on excision of the appendix. At the operation a cord-like
formation was found passing from the appendix abscess
to the left ureter, leading to acute flexion of it, and
retention of urine in the kidney, besides this, infection
had taken place from the pus, so that pyelitis had
occurred. Permanent recovery took place after removal
of the cord-like structure and the appendix.

Hr. Dührssen read a paper on

SIMULTANEOUS DISEASE OF THE APPENDIX AND THE FEMALE PELVIC ORGANS.

He said it was the duty of the gynæcologist to treat other diseases of the abdomen in the course of operation for disease of the female pelvic organs. For years he had turned his attention to the relations of the gall-bladder, and also to changes in the vermiform appendix, which he had removed nine times in a total of 320 abdominal operations. He had noticed that in disease of the adnexa, appendicitis and attachments of intestine to the adnexa and the broad ligament were not infrequent. The appendicitis was always simple. Sometimes in the case of large pelvic abscesses he had removed the adnexa, the vermiform appendix, and the uterus. He recommended the incision in the linea alba.

Dr. Kummel, Hamburg, related
Two Cases of Resection of the Descending Colon
with Suture of the Transverse Colon to the
Sphingter Ani.

The first case was a man of 20 suffering from high reaching carcinoma of the descending colon. The rectum and the diseased sigmoid flexure were removed. The transverse colon was then brought down and out through the anus, twisted and sutured in position. Recovery. The second case was that of a woman who had an artificial anus made fifteen years previously for carcinoma. The ulceration extended very high up. Resection was performed, the transverse colon drawn down, twisted,

and sutured in as before. At first there was collapse, but the patient rallied. Then acute ileus came on and laparotomy was again performed. Two necrotic loops of intestine were found in the small pelvis; these were drawn out and resected. After some months the patient was discharged cured.

THE KAISER FREDERICK QUELLE (SODA LITHIA SPRING).

This spring, as is known, is at Offenbach on the Rhine. With great labour, and after long and persevering effort, a boring was effected reaching a depth of 275 metres, or not much less than 1,000 feet. At this depth an abundance of remarkably clear odourless sparkling water gushed forth, which, on being tested, proved to have useful medicinal properties. From an analysis by the well-known Professor Fresenius, of Weisbaden, and others, we learn that the water contains the carbonates of lithium, sodium, and ammonium, some sodium sulphates, and a relatively active quantity of sodium chloride. The water, therefore, may be designated as an alkaline saline, and it is principally distinguished among the group of useful mineral water by its relatively large percentage of lithium carbonates. It is further distinguished from others of the group by the small amount of contained am. carbonate, magnesium, bicarbonate, and free carbonic acid. On first coming from the spring the water is neutral in reaction, but it quickly becomes distinctly alkaline. Its absolute purity as regards germs is guaranteed by the enormous depth from which it springs.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 20th, 1899.

LY88A ANIMALIA.

Kraus read a report of the experiments which he, in common with Paul, has recently made on birds, with the object of testing how far the virus of hydrophobia is resisted by this class of animal. He finds that when the "subdural" membrane in hens, ducks, and geese is inoculated with the virus, the incubation lasts from eight to thirty days when a train of symptoms appears that reminds us much of the appearances met with in quadrupeds. There is a form of ataxia and paresis almost amounting to paralysis associated with these symptoms, but recovery is the general rule, while in quadrupeds it is the exception. Pigeons and crows seem to be quite refractory. The infected membrane of the bird cannot be made to transmit the virus to a guinea-pig.

HEREDITARIA TARDA.

Berdach exhibited a young boy, æt. 16, with hereditaria tarda, which appeared three years ago in the form of periosteal thickenings on the tibia, the upper part of the arm, and left clavicular region. It may be noted that none of Hutchinson's trias, such as formation of teeth, otitis interna, or keratitis parenchyma, were present. Father and mother were decidedly syphilitic before the birth of the child. No symptom of a secondary stage seems to have been present.

ANCHYLOSTOMA DUODENALE.

Hugo Goldmann, who is medical officer for the "Brennberg im Oldenberger" Company, read a long paper on the history, habitat, symptoms, and treatment of the disease.

The parasite was for the first time described in 1883, when it was found in the bowel of the human subject. Its natural habitat is Brazil, India, Borneo, and Egypt, which from the latter in derived the name of Egyptian chlorosis. In 1880, during the construction of the St. Gothard tunnel, the same malady went under the name of "tunnel disease," or mountain cachexis.

Since that time it has been discovered to exist more or less in works of this kind over the whole of the Continent.

The parasite is male and female, the female being fifteen millimetres long while the male is only ten millimetres. The latter is distinguished from the former by a bursa copulatrix and a spicula. Its colour is reddish brown, sometimes grey, and it has no segmental construction. The head is bell-shaped, supported by a chitine arrangement; the mouth capsule has four large ventral and two small dorsal teeth.

The bowel is almost straight, while the stomach is recognised as a dilatation in its centre. The seminal duct leaves the ventral part of the body about the middle. The ovules appear in a small irregular adherent mass which undergo segmentation and develop a larva which afterwards pass through a stage of cystation. After complete development the parasite, with its bell head, seizes the mucous membrane with its teeth through which it bores with a small stiletto. The duodenum is the usual site, but it is not infrequently found in the jejunum and ileum in enormous quantities, even exceeding 1.500.

The disease is usually ushered in by characteristic malaise, exhaustion, feebleness of the extremities, headache, flickering of the eyes, noise in the ears, increased flow of saliva, and pyrosis. The general appearance is anemic, with sub-icteric colour associated with rapid emaciation. There is frequently dilatation of the heart, accompanied with a blowing systolic murmur. abdomen is distended and tender to touch. The patella reflex is increased; pulse soft and averaging about 120; respirations, 40; temperature, 38½ degs. C., or 101½ degs. Fahr.; no albumen in the urine. A frequent warning is blood-coloured stools, in which the ovum may be discovered. The blood examination is sometimes chlorotic, although the hæmoglobin is increased. The eosinophile cells are in greater number, and the reaction of ptomaines can be obtained.

The prognosis depends very much on the constitution although it is more severe in northern climates. As a rule it may be given as favourable if the disease be attacked energetically. Pulmonary tuberculosis is the chief danger,

The treatment is varied—thymic acid in doses of about one-tenth of a gramme in the form of an oblate after meals; extract filicis. max. in capsules, preceded by four-tenths of a gramme of calomel, is also highly recommended.

The Operating Theatres.

ST. PETER'S HOSPITAL FOR STONE.

SUPEA-PUBIC LITHOTOMY IN A CASE OF LARGE STONE PAIN PAIN ENLARGED PROSTATE RENDERING LITHOLAPAXY AND ENLARGED PROSTATE RENDERING LITHOLAPAXY IMPOSSIBLE.—Mr. SWINFORD EDWARDS operated on an old man, æt. 72, who had been admitted for symptoms of vesical calculus. The patient had 10 years previously there was no pain nor tenderness, and no fever. The

undergone lithotrity at the hands of the same surgeon. On sounding him a large stone was felt lying behind an hypertrophied prostate. An endeavour was made to crush the stone by means of the largest lithotrite which could be introduced (it was found impossible to pass Bigelow's large instrument) and although by this means large pieces were shaled off the stone, the calculus could not be fairly broken, therefore a supra-pubic operation was decided upon. Mr. Edwards tried to distend the bladder but this was found to be impossible as it would only hold about two ounces of fluid. A silver catheter through which the viscus had been injected was left in situ to act as a guide. cutting down above the pubes, the bladder wall was found to be much hypertrophied; there seemed to be at least one-third of an inch of tissue thickness between the finger in the wound and the inlying catheter. The bladder was now incised, and the stone with some difficulty extracted owing to its size. Part of the circumference was found to have been broken off and lay in fragments around it in the bladder. All these were extracted by means of forceps and scoop after the stone itself had been removed. A large rubber drainage tube was now inserted, and the bladder freely flushed out with boracic acid solution. The tube having been made fast to the parieties, the upper and lower extremities of the wound were brought together by silkworm gut sutures, two sutures of the same material having previously been employed to bring together the abdominal aponeurosis. Mr. Edwards commented upon the enormously thickened bladder wall, and upon the conformation of the interior of the viscus: he found on introducing his finger that the base with the posterior wall was practically divided into two compartments by an enormously hypertrophied inter-ureteral bar which thus divided the deep post-prostatic pouch from the posttrigonal pouch, the prostate around the vesical orifice was found to be enlarged and bossy. He remarked that having failed to pass an instrument sufficiently large to crush the stone, two courses appeared to be open to him, one being a perineal lithotrity, and the other the one he had selected. reasons for preferring the latter to the former were that he considered it a better operation where the prostate was so hypertrophied. In cases of a large stone which cannot be crushed, and in which the prostate is not appreciably enlarged, he considered that a median perineal cystotomy with crushing of the stone in situ is a better operation than the supra-pubic cystotomy as it affords better drainage. The stone was smooth excepting where the outer surface had been chipped off by the lithotrite, it was evidently composed of uric acid, and its weight was estimated at about three ounces.

MIDDLESEX HOSPITAL.

RELAPSING APPENDICITIS. APPENDECTOMY.—MR. ANDREW CLARK operated on a strong, healthy-looking girl, et. 25, who had been admitted for continuous pain in the right iliac region; she had suffered from a similar pain some months before, but had recovered under medical treatment. After admission on the present occasion, although vomiting was persistent for a few hours the pain partly subsided with rest, but was still most marked at McBurney's point, and although the symptoms of the acute attack quite disappeared after a few days there still remained slight rigidity over the right iliac fossa; there was no pain nor tenderness, and no fever. The

patient was anæsthetised, and an incision 3 inches long made over the region of the appendix. On introducing the finger; the appendix was immediately felt and drawn to the surface. There were no adhesions. The appendixlooked thickened and baggy. The mesentery of the appendix was transfixed and ligatured, and the process itself removed about half an inch from the cœcum, its peritoneum being dissected by a circular incision and stripped up, so that after the appendix had been ligatured and removed it could be sewn over the stump. The parts were then carefully swabbed with weak perchloride of mercury, the abdominal wall sewn up layer by layer, and the wound closed with collodion. Mr. Clark remarked that this was a case in which appendectomy had been determined on after the patient had had two distinct attacks, and, looking at the part removed, it would be seen that it was a case in which the operation was likely to be of the utmost benefit to the patient, for although no concretion, or indeed any evidence of disease beyond its puffiness could be observed, even after removal, yet on laying it open, the canal half an inch beyond where it was examined was found to be distended with pus; this would most assuredly have set up fresh trouble soon after the patient began to get about again. The operation itself, he pointed out, was about as simple as it could be, and gave rise to no difficulty in its performance. The case, he thought, rather tended to confirm the opinion of those who say that it is wisest to remove the appendix after a single attack, and not to wait until inflammation has occurred outside the appendix and given rise probably to localised suppuration.

"SALUS POPULI SUP EMA LEX."

WEDNESDAY, MAY 24, 1899.

MEDICAL JURISPRUDENCE OF INSANITY. This wide and much debated question, like the poor, is ever with us, and we are accustomed to hear many extreme views propounded, and sometimes not without reason. Professor Richard Brown, St. Mungo's College, Glasgow has, in the Law Magazine and Review for May, taken up the cudgels and fought the battle from a lawyer's point of view. We do not remember to have heard some of the arguments here given so emphatically, by any other lawyer, though it is conceivable that not a few legal luminaries have had them in their mind's eye. The article is written apropos the appearance of a recent work by Dr. Clevenger, of Chicago. It is somewhat on the lines of Isaac Ray in America, and Maudsley in this country. Professor Brown runs foul of Dr. Clevenger at the outset, and we confess to some approval of his stricttures on what seems a rather pedantic utterance. Clevenger opens thus:—"Precisely as the exactness of modern research in the field of mental disease is demonstrated to intelligent jurists, so will there be improvement of the common and statutory laws relative to insanity." Brown retorts, "We take this to mean that every change in the medical view of insanity must be accompanied by a corresponding change in legal responsibility. In other words, every departure from the normal, which justifies a medical man in declaring a person insane, absolves that person from the legal consequences of a criminal act." This is, perhaps, too free a rendering, and the word justifies begs the question. If the diagnosis is justified then Professor Brown has no case. It is much too soon, however, for Dr. Clevenger to speak of the exactness of modern research in the field of mental disease as a medico-legal quantity, whatever we may say of it in the histological department of the same field. The lawyer's view is that "writers like Dr. Clevenger view the law only from the standpoint of medicine, and ignore the true object of legal punishment which is the safety and security of society," or in the words of the old Scottish indictment "that others may be deterred from committing the like crimes in all time coming." And yet crime does not cease! What then is the efficacy of the remedy. He holds strong views on the subject of socalled moral insanity, or moral imbecility, and with these we strongly sympathise. Here the physician is apt to go beyond the physician's province, and talk of responsibility which is really a judicial question. In the case of innate depravity in contradistinction to moral imbecility-if any such distinction can be drawn, Ray says, "the law must take its course," but Professor Brown adds, "We may fairly ask whether it is not quite as open to the man of 'innate depravity' to say 'I could not help it,' as to any 'moral imbecile.'" He thinks, and, we fear, truthfully, that sympathy does enter into the medical treatment of such cases. "On the one hand, the presence in the community of strong personal or sympathetic feelings often excites an unreasoning fury against the perpetrator of an atrocious crime. . . On the other hand, we sometimes lose sight of the wrong done, and allow our sympathies to concentrate themselves upon the circumstances and surroundings of the criminal." such views we must, to some extent, concur, and medical men, and especially asylum medical men, will find this review a wholesome and helpful one.

Unfortunately, medical expert evidence is not yet regarded with the unqualified favour that it might receive if medical men themselves were careful not to take sides in a case, as they are apt consciously, and often unconsciously, to do.

THE SELECTION OF ENGLISH POOR-LAW MEDICAL OFFICERS.

WE have received a circular letter calling attention to the special circumstances attending the recent appointment of medical officers by the Bradford Board of Guardians which raises several questions of general interest. It is asserted that the guardians have departed from the time-honoured custom of throwing such posts open to competition, and have, instead, selected two particular medical men, excluding applications from other practitioners. There seems to be a considerable amount of commotion among the medical profession in Bradford at the present time in consequence. We are not quite sure that we understand the precise merits of the controversy which appears to have divided the profession in the stirring democratic city into two or more camps; but so far as we can gather, there seems to have been a considerable amount of difference of opinion on the question of abuse of the medical charities. Some members of the profession hold that there is gross abuse of the charities, and strenuously assert that many persons, well able to pay for medical services, persistently, and for many years past, have made use for private purposes and from sordid motives of funds collected, avowedly for the relief of the poor of the city. Other members of the profession, on the contrary, allege that while, no doubt, some amount of abuse may be shown to obtain in the distribution of the relief given by the medical charities, that abuse is no greater than must necessarily attach to all charities while human nature continues to be what it is, a little too much inclined to selfishly grasp to itself what was intended for less favoured parties; but they say that on the whole no great amount of abuse has been shown to exist. Naturally, perhaps, the outside practitioners seem to take the former view, while the members of the various hospital staffs seem to incline to the latter. There are numerous exceptions, no doubt, and probably a good deal more will be heard on both sides respecting the merits of the controversy and the various facts of the case. The question is by no means settled, and we are not yet in possession sufficient materials to enable us to form an opinion. But one great fact seems to be certain-viz., that on this question the divergency view has been so great that a great many medical practitioners, while they do not seem to have left the older medico-ethical society, in whose deliberations they still take part, and at whose meetings they vote, have yet thought it advisable to found a new society called the Bradford and West Riding Medical Union, and it appears to be the secretaries of this new society who have issued a circular convening a meeting of the whole profes-

sion in Bradford and the district. The meeting was duly held, and was very largely attended. Certain medical practitioners appear to feel aggrieved that the guardians have made appointments to posts paid for out of the ratepayers' money without throwing those posts open to public competition. If this be so it is a view for which, in our opinion, much may be said. Probably the guardians are acting within their legal rights. No doubt they have been advised in this sense. We have no wish to question their right. But as to the expediency of the course they are taking surely much is to be said. We have not a word to say against the gentlemen they have appointed, or as good as appointed. No doubt their standing, if somewhat youthful, justifies the confidence, the "complete confidence," which the guardians are said to repose in them. Neither do we even say, if the guardians "offered" these gentlemen the appointments, as we are told they have done, the gentlemen were bound to raise any difficulty as to accepting them. That was a question which appealed to their discretion. Both Dr. Campbell and Dr. Crowley withdrew on a previous occasion for reasons which, at that time, seemed convincing, but which do not now seem adequate to Dr. Crowley. But it does seem strange to us that "eminent local physicians, surgeons whose knowledge and skill involve them in being summoned in a consultative capacity," are not thought good enough by the guardians to be allowed even to compete for the posts, although evidently the general public think them good enough to be called in in consultation with their own family attendants. That general public, as ratepayers, contribute to the payment of the salaries of the gentlemen who are thus thought so supremely fitting for the new posts that no others need apply, even if they are willing to do so, which, of course, may or may not be the case. Perhaps the practitioners in question may be too busy to do the work of the new posts properly. But if so, they would not apply for the posts. If they did apply it would be because they felt they were able to find time to do the work. Surely that is a point which might have been left to their own discretion. But if ratepayers call in consultation with their family attendants eminent local practi tioners, when their own lives are at stake, it is curious that they should think those same practitioners ought to attend to the lives and health of paupers in the workhouse. Of course the eminent local practitioners might not have wished to apply for the posts. But on what grounds of public utility should they have been prevented from doing so, if they did wish? On this point no information appears to be offered. It may fairly be asked whether the guardians, in the exercise of their authority, and in their discretion as representatives of the ratepayers, have been sufficiently careful in this matter to avoid even the appearance of jobbery or of favouritism, of which we do not, indeed, accuse them in this case, but which it is quite evident might, in other circumstances, be construed in such a sense? There is another aspect

of the question which is evident even to the lay mind, since the Bradford Observer refers to it. Physicians and surgeons who do not take general practice are dependent for a large part of their practice on the goodwill of general practitioners. Do the gentlemen in question sufficiently realise how much they may be affected in the future by a feeling or by a possible feeling in the minds of practitioners who might call them in in consultation, that these very men were depriving the practitioners of emoluments and of offices, which they might think ought to have been filled by themselves? This is a very grave question, indeed, for Dr. Crowley and Mr. Hall. Are we to understand that, in a district so rich as Yorkshire and as cities in the West Riding, competition in the medical profession is so keen that pure physicians and pure surgeons actually accept appointments which practitioners have been in the habit of filling? may not the practitioners in self-defence proceed to inquire whether there is, after all, so much in a name as has been supposed, and whether a so-called pure physician and pure surgeon is any better for the purpose of helping the general practitioner than the "eminent local physicians and surgeons" whom they have been in the habit of consulting! Is not one of the chief reasons why there are pure physicians and pure surgeons at all, because in no circumstances will such men compete with general practitioners? And if so, may not the practitioners think that in transferring their consultations from eminent local practitioners to pure physicians and pure surgeons, they may have escaped one form of competition indeed, only to fall into another quite as grave, or even more so? We shall await the issue of the position in Bradford with some interest.

GONORRHŒAL SALPINGITIS AND ITS PREVENTION.

THE recognition of the far-reaching effects of gonorrhea in the female constitutes quite a recent addition to our knowledge of the subject. At one bound gonorrhea, formerly regarded as almost a trivial disease when it affected the female generative organs, has come to be regarded as a potential factor in the production of far-reaching and grave consequences. Our information on this subject is still far from complete, and great interest, therefore, attaches to the record of collective investigation and experience such as we are enabled to offer to our readers in the papers read and discussed at the last meeting of the British Gynæcological Society. Mr. J. W. Taylor, of Birmingham, brought forward an interesting series of cases pointing to conclusions which embody sundry elements of novelty, notably in respect of the often unsuspected association of syphilis and gonorrheea in the same subject. He has found as a matter of experience that in cases of salpingitis it is oftener much easier to elicit a history of syphilis than of gonorrheal discharge. We are justified in supposing that gonorrhea cannot be the only factor at work in the production of this serious i ticket, whatever that may mean.
